LINE, *n. s.*

LIN'EAGE,

LIN'EAL, *adj.*

LIN'EALLY, *adv.*

LIN'EAR, *adj.*

LIN'EATION, *n. s.*

Fr. *line*; Lat. *linea*. The path of a mathematical point: extension longitudinally; limit: hence sketch; outline; marks or features of the hand or

face; contour; an extended thread or string; family, ascending or descending; and, particularly, the equinoctial circle; a rank, or disposition, of soldiers; a trench, or work, in fortification; as much as is written, or printed, from margin to margin in a book or manuscript; a verse; a measure of extension, containing one-tenth of an inch: lineage is race; progeny; family: lineal, containing or composed of lines; in direct descent; hereditary: lineally, in a direct line: lineal, composed of lines: lineation, lineal form; draught of a line, or lines.

And it hadde a wall greet and high hauynge welue ghat, and in the ghat of it twelue aungelis and names written yn that ben the names of twelue *nagis* of the sones of Israel. *Wiclif. Apoc. xxi.*

Their *line* is gone out through all the earth; and their words to the end of the world. *Psalm xix. 4.*

Joseph was of the house and lineage of David. *Luke.*

O Conqueror of Brut's Albion!

Whiche that by *lync* and fre eleccion

Ben very kings. *Chaucer. Unto the Kinge.*

Let calle thyn trewe frendes alle, and thy *linage*, which that ben wise, and telleth to hem your cas, and herkeneth what they saye in counseilling, and overne you aftir hir sentence. *Id. Cant. Tales.*

Both the *linage* and the certain sire
From which I sprung, from me are hidden yet. *Spenser.*

I shall have good fortune; go to, here's a simple one of life; here's a small trifle of wives. *Shakspeare.*

Long is it since I saw him,
But time hath nothing blurred those *lines* of favour
Which then he wore. *Id.*

He chid the sisters.
When first they put the name of king upon me,
And bade them speak to him; then, prophet-like,
They hailed him father to a *line* of kings. *Id.*

Queen Isabel, his grandmother,
Was *lineal* of the lady Ermengere.

Peace be to France, if France in peace permit
us just and *lineal* entrance to our own. *Id.*
(Knowledge) A climbing height it is, without a

head,
Depth without bottom, way without an end;
circle with no *line* environed,
not comprehended, all it comprehends,
orth infinite, yet satisfies no mind
ill it that infinite of the Godhead find.

Sir Fulke Greville.
The Tirsan cometh forth with all his generation or
age, the males before him, and the females following
him; and, if there be a mother from whose body

the whole *lineage* is descended, there is a traverse where she sitteth. *Bacon.*

Here, while his canting drone-pipe scanned

The mystic figures of her hand,

He tipples palmestry, and dines

On all her fortune-telling *lines*. *Claaveland.*

When the sun below the *line* descends,

Then one long night continued darkness joins. *Creech.*

If he had been the person upon whom the crown had *lineally* and rightfully descended, it was good law. *Clarendon.*

Eden stretched her *line*

From Auran eastward to the royal towers

Of great Seleucia. *Milton's Paradise Lost.*

His empire, courage, and his boasted *line*,

Were all proved mortal. *Roscommon.*

Well sung the Roman bard; all human things,

Of dearest value, hang on slender strings;

O see the then sole hope, and in design

Of heaven our joy, supported by a *line*. *Waller.*

Victorious with their *lines* and eyes,

They make the fishes and the men their prize. *Id.*

You have generous thoughts turned to such speculations; but this is not enough towards the raising such buildings as I have drawn you here the *lines* of, unless the direction of all affairs here were wholly in your hands. *Temple.*

We as by *line* upon the ocean go,

Whose paths shall be familiar as the land. *Dryden.*

Now snatch an hour that favours thy *designs*,

Unite thy forces, and attack their *lines*. *Id.*

A golden bowl

The queen commanded to be crowned with wine,

The bowl that Belus used, and all the Tyrian *line*. *Id.*

O that your brows my laurel had sustained!

Well had I been deposed if you had reigned:

The father had descended for the son;

For only you are *lineal* to the throne. *Id.*

Men of mighty fame,

And from the immortal gods their *lineage* came. *Id.*

To re-establish, de facto, the right of *lineal* succession to paternal government, is to put a man in possession of that government which his fathers did enjoy, and he by *lineal* succession had a right to. *Locke.*

A *line* seldom holds to strain, or draws straight in length, above fifty or sixty feet. *Mozon.*

The years

Ran smoothly on, productive of a *line*

Of wise heroick kings. *Philips.*

In moving *lines* these few epistles tell

What fate attends the nymph who loves too well. *Garth.*

The real *lineage* and succession of wit is plainly

founded in nature. *Shafesbury.*

No longer shall the widowed land bemoan

A broken *lineage*, and a doubtful throne,

But boast her royal progeny's increase,

And count the pledges of her future peace. *Addison.*

Sir Fulke Greville.

The Tirsan cometh forth with all his generation or

age, the males before him, and the females following

him; and, if there be a mother from whose body

VOL. XIII.—PART 1.

B

They pierce the broken foe's remotest lines. *Id.*

The soul, considered with its Creator; is like one of those mathematical lines that may draw nearer to another for all eternity without a possibility of touching it: and can there be a thought so transporting, as to consider ourselves in these perpetual approaches to him, who is not only the standard of perfection, but of happiness! *Addison.*

When any thing is mathematically demonstrated weak, it is much more mechanically weak; errors ever occurring more easily in the management of gross materials than *lined* designs. *Wotton.*

Where-ever it is freed from the sand stone, it is covered with *linear* strim, tending towards several centers, so as to compose flat stellar figures.

Woodward on Fossils.

There are in the horney ground two white *lineations*, with two of a pale red. *Woodward.*

Even the planets, upon this principle, must gravitate no more towards the sun; so that they would not revolve in the curve *lines*, but fly away in direct tangents, till they struck against other planets.

Bentley.

Oh lasting as those colours may they shine,
Free as thy stroke, yet faultless as thy *line*! *Pope.*

In the preceding *line*, Ulysses speaks of Nausicaa, yet immediately changes the words into the masculine gender. *Broome.*

There is a sort of masonry in poetry, wherein the pause represents the joints of building, which ought in every *line* and course to have their disposition varied. *Shenstone.*

To dote on aught may leave us, or be left,
Is that ambition! then let flames descend,
Point to the centre their inverted spires,
And learn humiliation from a soul
Which boasts her *lineage* from celestial fire.

Young.

A poet does not work by square or *line*,
As smiths and joiners perfect a design;
At least we moderns, our attention less,
Beyond the example of our sires digress,
And claim a right to scamper and run wide,
Wherever chance, caprice, or fancy guide.

Cowper.

Nor less amazed, that such a blot
His noble 'scutcheon should have got,
While he was highest of his *line*.

Byron.

LINE, *v. a.* } From LINEN, which see; or
LIN'ING, *n. s.* } Lat. *linum*. To cover inside;
to guard or protect within; place within; double;
impregnate: a *lining* is an inward covering or guard.

Her women are about her: what if I do *line* one
of their hands? *Shakspeare. Cymbeline.*

Line and new repair our towns of war
With men of courage, and with means defendant.

Shakspeare.

Son of sixteen,
Pluck the *lined* crutch from thy old limping sire.

Id.

Who *lined* himself with hope,
Eating the air on promise of supply. *Id.*

The *lining* of his coffers shall make coats
To deck our soldiers for these Irish wars. *Id.*

The two armies were assigned to the leading of two generals, both of them rather courtiers, and assured to the state, than martial men; yet *lined* and assisted with subordinate commanders of great experience and valour. *Bacon.*

The charge amounteth very high for any one man's purse, except *lined* beyond ordinary, to reach unto.

Carew.

Let no man tell me now of that just wonder of the world, the Jewish temple; white marble without, *lined* with gold within. *Bp. Hall.*

Thus from the Tyrian pastures *lined* with Jove,
He bore Europa, and still keeps his love. *Creech.*
Notwithstanding they had *lined* some hedge
with musqueteers, they were totally dispersed.

Clarendon.

Was I deceived, or did a sable cloud
Turn forth her silver *lining* on the night?

Milton.

A box *lined* with paper to receive the mercury that might be spilt. *Boyle.*

The fold in the gristle of the nose is covered with a *lining*, which differs from the facing of the tongue *Grew's Cosmologia.*

The gown with stiff embroidery shining,
Looks charming with a slighter *lining*. *Prior.*

He, by a gentle bow, divined
How well a cully's purse was *lined*. *Swift.*
Nor name nor title, stamped behind,
Adorns its outer part;

But all within 'tis richly *lined*,
A magazine of art.

Cowper.

LINE, EQUINOCTIAL. See ASTRONOMY.

LINE, GUNTER'S, a logarithmic line, usually graduated upon scales, sectors, &c. It is also called the line of lines, and line of numbers; being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into 100 parts, every tenth of which is numbered, beginning with 1 and ending with 10: so that if the first great division, marked 1, stand for one-tenth of an integer, the next division, marked 2, will stand for two-tenths, 3 for three-tenths, and so on; and the intermediate divisions will in like manner represent 100th parts of the same integer. If each of the great divisions represent ten integers, then will the less divisions stand for integers; and, if the greater divisions be supposed each 100, the subdivisions will be each ten. 1. To find the product of two numbers. From 1 extend the compasses to the multiplier; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus, if the product of 4 and 8 be required, extend the compasses from 1 to 4, and that extent laid from 8 the same way will reach to 32, their product. 2. To divide one number by another. The extent from the divisor to unity will reach from the dividend to the quotient: thus, to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought. 3. To three given numbers to find a fourth proportional. Suppose the numbers 6, 8, 9: extend the compasses from 6 to 8; and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required. 4. To find a mean proportional between any two given numbers. Suppose 8 and 32: extend the compasses from 8, in the left-hand part of the line, to 32 in the right; then, bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought. 5. To extract the square root of any number. Suppose 25: bisect the distance between 1 on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In

L I N E N.

the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line between 1 and the given number into as many equal parts as the index of the power expresses; then one of those parts set from 1, will find the point representing the root required.

LINE, MERIDIAN. See **GEOGRAPHY** and **ASTRONOMY**.

LINE OF BATTLE is the disposition of the fleet in the day of engagement, on which occasion the vessels are usually drawn up as much as possible in a straight line, to gain and keep the advantage of the wind and to run the same board. See **NAVAL TACTICS**.

LINE, SHIP OF THE, a vessel large enough to be drawn up in the line, and to have a place in a sea-fight.

LINEA ALBA, in anatomy, the concourse of the tendons of the oblique and transverse muscles of the abdomen; dividing the abdomen in two in the middle. It is called *linea*, line, as being straight; and *alba*, from its color, which is white.

LINE'AMENT, n. s. Fr. *lineament*; Lat. *lineamentum*. From **LINE**, which see. Feature; discriminating mark.

Noble York

Found that the issue was not his begot:

Which well appeared in his *lineaments*,

Being nothing like the noble duke, my father.

Shakspeare.

Man he seems

In all his *lineaments*, though in his face

The glimpses of his father's glory shine.

Milton.

God our parent hath stamped on our nature some
lineaments of himself, whereby we resemble him.

Barrow.

There are not more differences in men's faces, and the outward *lineaments* of their bodies, than there are in the makes and tempers of their minds; only there is this difference, that the distinguishing characters of the face, and the *lineaments* of the body, grow more plain with time, but the peculiar physiognomy of the mind is most discernible in children.

Locke.

The utmost force of boiling water is not able to destroy the structure of the tenderest plant: the *lineaments* of a white lily will remain after the strongest decoction.

Arbuthnot.

I may advance religion and morals, by tracing some few *lineaments* in the character of a lady, who hath spent all her life in the practice of both. *Swift*.

These are the moral attributes of the Divine Being, in which he requires us to imitate him; the express *lineaments* of the divine nature, in which all good men bear a resemblance to him; and for the sake of which only they are the objects of his delight. *Mason*.

LIN'EN, n. s. & adj. Sax. *linen*; Goth. *lin'ener*. *Lin*; Teut. *lein*, flax; Lat. *linum*; Gr. *λινον*. Cloth of hemp or flax.

And they took the body of Jesus and bounden it in *linnum* clothis with sweete smellynge oynementis, as it is the custom to iewis for to byrie.

Wiclif. Jon. xx.

Here is a basket, he may creep in; throw foul *linen* upon him, as if going to bucking. *Shakspeare*.

A *linen* stock on one leg, and a kersey boot hose on the other, gartered with a red and blue list. *Id*.

Death of thy soul! those *linen* cheeks of thine
Are counsellors to fear, What soldiers, whey-face?
Id.

Where is my fashioner? my feather-man?
My *linener*, perfumer, barber? *Ben Jonson*.

Unseen, unfelt, the fiery serpent skims
A her *linen* and her naked limbs.

Dryden.

...ered spendthrift, whose fantastic air,
...oned figure, and cockaded brow,
...a charge, and underneath the pride
Of costly *linen* tucked his filthy shroud. *Young*.

A drawer, it chanced, at bottom lined

With *linen* of the softest kind,

With such as merchants introduce

From India, for the ladies' use.

Cowper.

LINEN. The fabrication of linen is a most important branch of the staple manufactures of Great Britain. On this account we have already fully examined the agricultural processes connected with the cultivation of flax; the dressing of hemp has also been briefly considered, and we must now proceed to the operation of spinning.

The most ancient mode of *spinning* is by the spindle and distaff, and this method is the simplest of all others. The spindle is nothing more than a piece of hard wood, made round, and sharp pointed at one end, so that it can be made to whirl upon its point in the same manner as a child's top: the upper part is reduced to a pin or peg, and it is this part which has the fibres united to it, the lower or enlarged part being only to give sufficient weight to make it revolve. The spinner must be seated upon the ground, and after having put the distaff in motion upon its point, by twirling it between the hands, get it up to a rapid motion by striking it occasionally with the hand, with a motion very similar to that by which a child keeps up the motion of his whipping-top, when he draws the lash of a whip round it.

The flax, after having been properly prepared, is lapped round the end of the distaff, which is nothing more than a stick that the spinner holds in his left hand, so as to be conveniently situated to draw off from it a few fibres at a time with the finger and thumb of the right hand, to form the thread. The upper part of the spindle, which is made smaller like a pin, has the ends of the fibres which are to form the thread attached to it before it is put in motion. These fibres are drawn out of the bunch which is wound upon the distaff, and held between the finger and thumb, so as to be in the direction of the length of the spindle; therefore, when the spindle is once made to revolve, it twists these fibres together, to form a thread, and, as fast as the thread forms, the spinner draws off more flax from the distaff, and guides the fibres between the finger and thumb, so that they shall be regularly delivered out, and make an even thread. The motion of the spindle is constantly kept up, by striking it as often as the hand can be spared from the operation of guiding the thread. When by these means as great a length of thread is formed as is convenient to reach from the end of it to the spindle, the thread is wound upon the outside of the small part or pin of the spindle, for which purpose the spinner applies the fore-finger against the thread, close to the end of the spindle, and bends the thread at that

part, so that it will be at right angles with the direction of the spindle, instead of being nearly in the direction of its length; and also, that it will be guided opposite to the middle of the pin, or small part of the spindle, instead of being at the extreme end thereof. In this situation the motion of the spindle, which is continually kept up, occasions the thread to wind up, or lap upon the pin of the spindle, instead of twisting round upon itself, as in the former case; but, when nearly all the length of thread is thus disposed of, the finger is removed from the thread, and it immediately assumes its original direction, by slipping to the extreme end of the spindle, so as to be twisted round itself by the motion of the spindle, and more fibres are now supplied to it from the bunch upon the distaff, to form a fresh length of thread. In this manner the spinning proceeds, until as much thread is spun and wound upon the pin of the spindle as will make a moderately sized ball.

This simple and inconvenient method of spinning becomes very efficient, when the spindle, instead of being spun upon the ground, is mounted in a proper frame, and turned by a wheel and band; this forms a machine which is called the one-thread wheel, and is still used in some parts of the country for spinning wool: the spindle is made of iron, and placed horizontally, so that it can revolve freely; and the extremity of the spindle, to which the thread is applied, projects beyond the support.

The wheel which turns it is placed at one side, the pivots of both being supported in upright pieces, rising up from a sort of stool. The spinner puts the wheel in rapid motion by its handle, and its weight is sufficient to continue the motion for some seconds; then walking backwards from the spindle, in the direction of its length, she supplies the fibres regularly, and the motion twists them into a thread; but, when a convenient length is spun, the spinner steps on one side, and reaches out that arm which holds the end of the thread, so as to alter the direction of the thread, and bring it nearly perpendicular to the length of the spindle, which motion gathers or winds up the thread upon the middle of the projecting part of the spindle. This being done, she holds the thread in the direction of the spindle, so that it will receive twist, and retreats again to spin a fresh length of thread.

A *spinning-machine* more perfect than this is the one-thread flax-wheel, with spindle and flyer; it has the property of constantly drawing up the thread as fast as it is spun, instead of spinning a length, and then winding it upon the spindle. For this purpose the spindle is made longer than the other, and is turned by a band and wheel; but the wheel receives motion from the foot by a small treadle, because the spinner sits before the wheel to work the spindle, which is supported upon its two extreme ends, and near one end the flyer is fixed, this is a piece of wood curved to an arc, the vertex of which is fixed on the spindle, and from the extremities of the arc two arms proceed, so as to be parallel to the spindle, and at such a distance from it as to admit a wooden bobbin to be fitted loosely upon the spindle; and at the same time the arms of the flyer can revolve round the bobbin without

touching it. The end of the thread is fastened to the bobbin, and conducted through a hook fixed in the flyer, so that it proceeds from the circumference of the bobbin to this hook, in a direction perpendicular to the bobbin, but turns round the hook so as to come into the direction of the spindle.

The thread is then conducted through a perforation made in the centre of the end of the spindle or pivot, upon which it revolves, and to this end of the thread the fibres are supplied. The twisting motion given by the revolution of the spindle forms them into a continuation of the thread, which is gathered up upon the bobbin as fast as the spinner lets it go through her fingers, by a tendency which the bobbin has to turn slowly, at the same time that the flyer to which the thread is hooked is revolving rapidly round the bobbin. For this purpose a string is passed round a small neck upon the bobbin, and, one end of the string being fastened to the frame, the other has a small weight to draw it tight round the neck of the bobbin, and occasion friction.

In other spinning wheels a second band from the great wheel is made to turn the bobbin more slowly than the spindle. The thread which passes over the hook of the flyer is rapidly carried round the circumference of the bobbin; but, as the bobbin follows the motion of the flyer, it only winds up as much thread upon the bobbin as the difference of the two motions; and this tendency to wind up can be increased or diminished at pleasure, by the friction which is occasioned by the string or band which passes round the neck of the bobbin. When the winding-up of the thread upon the bobbin has accumulated a ridge of thread, upon it opposite to the hook in the flyer, the thread must be shifted to another hook opposite to a different part of the bobbin, for which purpose the arms of the flyer are furnished with different hooks, and this must be repeated several times, until the whole length of the bobbin is filled; it is then taken off to be reeled, and replaced by another empty bobbin.

An improvement was made in the *spinning-wheel* by Mr. Antis some years ago, which was an application of what Sir Richard Arkwright had before invented. The object is to obviate the necessity of stopping the wheel to remove the thread from one hook to another, in the manner just described. For this purpose, the bobbin is made to move regularly backwards and forwards upon the spindle a space equal to its length, so that every part will, in succession, be presented opposite the hook over which the thread passes, and thus receive the thread regularly upon the whole length of the bobbin. The additional parts necessary for producing this movement are as follow: a pinion of only a single leaf is made to project from the extremity of the pivot of the great wheel, or a worm or endless screw formed on the end pivot will answer the same purpose, which is to actuate a wheel of seven inches diameter, and ninety-seven teeth; therefore ninety-seven revolutions of the great wheel will produce one revolution of this smaller wheel; upon the face of which a circular ring of wire is fixed, and supported from the wheel by six legs, so as to be oblique to the plane of the

wheel, as it touches it at one part, and at the opposite side of the ring projects nearly three-quarters of an inch. This ring of wire gives motion to an upright lever, about fifteen inches long and moving on a centre at three inches from its lower extremity, where it has a pin fixed in it and resting against the oblique ring of wire; and therefore, when the wheel turns round, it communicates a small motion to the lever in consequence of its obliquity to the plane in which it revolves. The upper end of the lever is connected to an horizontal sliding-bar situated beneath the spindle, and having an upright piece of brass, which works in the notch of a pulley formed in the ends of the bobbin, and drives the bobbin backwards and forwards upon the spindle, according as the oblique ring of wire forces the pin at the lower end of the lever in or out, when the wheel moves round. To regulate and return this alternate motion, a small weight hangs by a line to the sliding-bar, and, passing over a pulley, rises and falls as the bobbin recedes and advances, and tends constantly to keep the pin at the lower end of the lever in contact with the wire. It is evident from this description, that one staple only is wanted to the arms of the flyer, which being placed near the extremity, the thread passes through it, and by the motion of the bobbin is laid regularly upon it from one end to the other.

The invention has also another advantage over the old method, which always winds the thread in ridges upon the bobbin; and, if the thread breaks in reeling the yarn, the whole bobbin may as well be thrown away, because the thread cannot easily be found again; but this improved wheel always winds the threads across upon one another, by which means the end can never be lost.

In order to regulate the friction on the bobbin, and retard its motion in a greater or less degree at pleasure, there is a neck of brass or steel fastened to one end of it, and embraced by a kind of small vice, or pincers, fixed to the sliding-bar. This vice must be made either with two elastic springs with wooden tops, or of wood wholly, and faced with leather; but, if made of wood only, then a spring must be made beneath the shoulder of the screw, to answer the same purpose. By tightening this screw, more or less, the friction on the bobbin may be regulated to the greatest nicety, provided the springs are of a strength rightly proportioned to their functions. It will readily appear, that all this may be done without the least effect on the velocity of the whole machine, as thereby nothing is added to the general friction so as to obstruct it.

We shall now proceed to give a description of a patent, obtained in 1806, by Messrs. Clarke and Bugby, for effecting certain improvements in a *machine*, intended to be worked by hand-labor, for the spinning of hemp, flax, &c.:—

Plate LINEN MANUFACTURE, fig. 1, represents an oblique view of the front of a frame containing ten spindles (but the frames may contain an indefinite number of spindles). A, the spindle or a bow passing through the whole frame, having ten bosses of brass or cast-iron thereon, each about four inches diameter, each boss supplying one spindle; B, a pinion of twelve leaves

upon the end of the spindle A, connected with the wheel C, of eighty teeth, fixed upon the end of a small iron spindle F, covered with wood, and extending through the whole frame; D, a slack or intermediate pinion of any size at discretion, connected with another similar pinion, the latter connected with a wheel of 120 teeth, which is fixed upon an iron spindle G, of about an inch and a half in diameter, and extending through the whole frame; but the wheels B, C, D, and F, may be varied in their numbers, to increase or diminish the draught of the substance operated upon, as may best suit its quality or the ideas of the workman. The pinion B is so contrived as to slip off the end of the spindle A, to make room for a smaller or larger one; by means whereof a larger or shorter thread may be spun from the same sized rovings; *a a a a a a a a a* represent ten roved slivers of hemp, flax, tow, or wool, passing between the iron spindle G and rollers in pairs pressed against them by springs or weights; these springs or weights must operate with sufficient force to hold back the slivers or rovings so securely, that they may only pass on with the movement of the spindle; these pairs of pressing rollers are placed behind the spindle. The use of the small iron spindle F, covered with wood, and left rather larger than the spindle G, is, with pressure of the small wood-roller, made up in pairs *b b b b b*, and so contrived that each pair may roll upon two slivers, to bring them down straight, and preserve the twist which they receive in the roving-machine till the slivers leave them. The bosses on the spindle A, have likewise wooden rollers in pairs pressed against them by springs or weights, between which the drawn, lengthened, or extended slivers pass to the spindle, the rollers having each a tin conductor, *c c c c c c c c c c*, to bring the material under operation as centrally as possible between the wood-rollers and the bosses; but all the above-mentioned parts of the machine are so similar to the common upright frames, that a person conversant with them will not be at a loss to understand its arrangement. H, is a wheel of wood four feet in diameter, having its rim about two inches thick, with a groove in its periphery for a small cord or band. In its centre is a rule or stock of wood, through which the spindle I passes, and extends into its frame about one-fourth of its length. To enable the person that turns the winch to reach all the spindles at work, with the hand that is not engaged in turning, to remove any obstacle that may arise to the spindles, the arbor or spindle of the wheel I has its bearing on the sides of the frame that contains it, marked *L L L L*; this frame, with the wheel H, the arbor I, and the winch K, is similar to that part of a machine called a mule-jenny, used for spinning cotton; this frame is supported in a horizontal position at the outer end by two legs marked *M M*, and a screw-pin which passes through K, the front upright A, fig. 2, and made tight with the thumb-screw *a*; the screw passes through a groove or mortise at the end of the wheel frame, to enable the workman to adjust the wheels N and O, as it will be found necessary to change the wheel N, to make such alteration in the twist as the size of the yarn may

require, or as the workman may think proper. P and Q are bevel wheels of equal size, the former fixed upon the rule or stock of the wheel H, and connected with Q upon the spindle R, taking round with it the wheel N, which is connected with the wheel O. Upon the embossed spindle or arbor A, *a a a a a a a a*, are spindles standing on a carriage with four wheels, similar to the carriages used in mule-jennies for spinning cotton, having at each of them, at *d d d d d d d d*, a convex seat of wood of any convenient size, not less than the bottom of the bobbins or quills *e e e e e e e e*; these bobbins or quills are about six inches long and one inch and a quarter diameter at the bottom, and three quarters of an inch diameter at the top; but the sizes must be varied according to the size of the yarn. Perhaps four or five variations will be sufficient to spin yarn for tarpaulins or sail-cloth, up to fine yarn fit for good dowlas and fine stockings. T, a pulley, over which a band, from S, runs and returns, to draw out the carriage upon the four wheels described; W, the cylinder which drives the spindles.

Fig. 2 exhibits a side view. A, the wheel mentioned above in fig. 1, and there marked H; B, the winch by which it is turned by hand; C C C C, the frame wherein it works; D and E are blocks of wood on each side of the said frame to raise the wheel, so that the winch may be clear of the carriage F F, and apparatus G G; the two end wheels upon the carriage containing the spindles having two more corresponding on the opposite side thereof. H, a groove upon the end of a cylinder, which drives the spindles, and stretches through the carriage-frame, for the diameter of which no certain rule can be laid down, as it depends upon the length or size of the yarn, taken into account with the other parts of the machinery. N N N N N N N, a small band passing over the wheels A K, H I L, and M, by which the groove-wheel H and its cylinder are moved, and the spindles driven. O, a treadle shaft, represented by S S, fig. 1, passing through the frame or part thereof at the option of the workman, connected with a tumbler at the end of the embossed spindle or arbor A, in fig. 1, by a small band, wound five or six times round each of them, and passing over the wood groove-wheel Q, and made fast to the back of the carriage F F; this tumbler, by the motion of A, is, at the return of the carriage, locked to the wheel R; and unlocked when the carriage is not in its proper situation.

The carriage is drawn on by the weight of S fastened to a cord, which passes over the groove-wheel T, and is connected with the front of the carriage; U, the wheel on the arbor containing the holder shown in fig. 1; V, the cylindrical roller on a stirr fixed therein, and rolling at every return of the carriage on the plane W and X, which raises and falls the fallers and holders, so as to distribute the yarn upon the bobbins from the top to bottom; the wheels Y Z, A 2, and B 2, are the same wheels shown by B, C, D, and E, in fig. 1; 1, 2, &c., spools containing the rovings.

This machinery is calculated to save the heavy expense of currents of water, erecting spacious buildings, water-works, steam engines, &c., and

to spin hemp, flax, &c., at such an easy expense as to bring it within the reach of small manufactories. This machinery is also constructed upon such safe and simple principles, that no length of experience is necessary to enable even children to work it; and the use of water, steam, &c., being rendered unnecessary, it occupies so little space, that it may be placed in small rooms, out-buildings, or other cheap places. To effect the above purpose, it was necessary to get rid of the lanier or flyer, upon the spindle used in the old machinery for spinning hemp and flax, which requires a power in proportion of five to one, and to surmount the difficulty that arose from the want of elasticity in these substances. This want of elasticity, in the substance to be operated upon, is compensated and provided for in this machinery; and upon this composition and provision, effected by the various means hereafter mentioned, the return of the carriage without any assistance from the work-person, and the traverse for distributing the yarn upon the bobbins or quills, lay the stress upon the patent. The most simple mode of compensating the want of elasticity, and which is recommended in preference to the other, is that of having a holder of large wire for every spindle, fixed in an arbor or shaft extending from one end of the carriage to the other.

This arbor or shaft, with the holders, may be considered as a large and improved substitute for what is called a faller in the mule-jennies for spinning cotton, fig. 3. Let A represent the arbor or shaft, *b b b b b b b b* the holders fixed therein with the elliptical eyes, through each of which a thread passes from the bosses on the arbor A, in fig. 1, to its spindle. B, a spindle, which may be from ten to thirteen inches long; C, the whirl, wherein a small worsted band from the cylinder H, fig. 2, works D, a convex seat upon the spindle, whereon the concave bottom of the bobbin or quill E rests.

F, a piece of buffalo skin, or metal, screwed or nailed to the rail I, having a hole in it, through which the spindle passes, and by which it is kept steady; G, a wire bent at right angles at *a*, and the bent part driven into the rail A, so that it may be removed to or from the whirl C, and, by the other crook *b*, prevent the spindle from running out of its step H, which is a screw of brass or other metal passing through the rail K. The wire of which the holder is made, after forming the elliptical eye, is left or extended beyond the uppermost part *a*, that the yarn may be conveniently slipped in when occasion may require it; these holders for each thread are for the purposes of keeping the yarn in a state nearly vertical over the tops of the spindles when the carriage which contains them is coming out, and being released from that situation at the beginning of the carriage's return, and thrown into nearly a horizontal position, so as to bring the yarn below the top of the bobbins or quills upon the spindles; and then being curved and raised again by the wheel U, and its cylindrical roller moving upon the plane W and X, fig. 2, distributes the yarn upon the bobbins or quills, and prevents it from cockling, hinkling, or improperly doubling or twisting together. The

seats upon the spindles described by D, are turned convex, and the bottoms of the bobbins and the bottoms of the quills concave, to keep the bobbins or quills in a more central state upon the seats. The concavity of the bobbins or quills, exceeding the convexity, throws the weight of the bobbins or quills upon the peripheries or extremities of the seats, and ensures the rotatory motions of the bobbins or quills with that of their spindles. We prefer the convex and concave surfaces before described; but other surfaces will have nearly the same effect, if so contrived (as they easily may be) to bear upon the peripheries or extremities of the seats, as well as of the bobbins or quills. The hole through the bobbin or quill, fig. 4, is rather larger than the spindle, that it may not be obstructed in its motion round the spindle, which motion takes place at every return of the carriage, and as often as any thing obstructs the coming forward of the sliver of which the yarn is formed. At one end of the arbor whereon the holders are fixed is a counterpoise L, fig. 3, having a socket, and made fast; the arbor by a thumb-screw *m*, the round ball at the top being led to counterbalance the holders. This counterpoise, when the holders are in a vertical state, declines about 10° or 15° towards the horizon; but when the holders are thrown down, and under the government of the cylindrical roller V, upon the wheel U, is in a different situation; but the roller V, arriving at B 3, fig. 2, on the return of the carriage, the holders are precipitated to a height where the counterpoise overbalances them, and locks the wheel M fig. 3, or U in fig. 2, in the ratchet *n*, where it remains until the carriage has reached its destined place, where the tail of the catch O strikes against the pin in a frame C C C C, fig. 2, and releases it, the said roller then resting upon the frame U X. A second method of compensating and providing for the want of elasticity in hemp and flax, which is a part of the discovery, is, to fix a round bar of wood, about an inch and a half in diameter, the whole length of the carriage, about three or four inches above the tops of the spindles, so that the outer surface, or that next the work-person, may be perpendicularly, or nearly so, over the tops of the spindles, the inner side having pieces of wood or metal nailed or otherwise fixed thereto, leaving only small spaces between each for the yarn to pass through; the use of these pieces is to prevent the threads getting together and entangling, see fig. 5. A A A A represents a common faller used in the mule-jennies for spinning cotton with counterpoise B, wheel C, with its cylindrical roller D, with the plane W and X, before described by figs. 1, 2, and 3; E E, spindles with their whirls, convex seats, bobbins or quills, with their concave bottoms; F F F F F F F F F F the pieces of wood or metal, nailed or otherwise fastened to the round piece of wood, to prevent the thread getting together. In this case every thing applied to or used with the arbor, containing the holders above mentioned, may be applied or used.

The bleaching of linen being a purely chemical art, it might be expected that the knowledge of the instruments it employs would keep pace

with the progress and improvements of that science to which it is subordinate, and so much the more as the nature of alkaline substances in general, which are its proper instruments, has been in a great measure explained by the celebrated Dr. Black. Yet it has so happened, when a scarcity of these saline substances unhappily prevailed in this kingdom, it was seriously questioned whether their place could be supplied by materials manufactured at home. Mr. Kirwan very minutely examined the various processes that had previously been resorted to, and the result of his labors is given in a very valuable paper in the Transactions of the Royal Irish Academy. He commences with barilla. Of this substance there are several sorts, made of different plants; but the best is that formed near Alicant, at a distance from the sea, by the combustion of a plant called by the inhabitants *barilla*, and described by Jussieu, in the memoirs of the Academy of Paris for 1717, under the name of *kali hispanicum, supinum, annuum, sedi foliis brevibus*. It seems to be classed by Linnæus under the pentandria digynia, by the name of *sal sola vermiculata frutescens foliis ovatis acutis carnosiss*, and should carefully be distinguished from the various kinds of *salicornia* which he ranges under the title of *monandria monogynia*; and also from other plants which he calls *chænopodia*, which yield an alkali, but less pure than the *salsola*. These plants, being dried to the same degree as hay, are burned in pits nearly as kelp is with us, the ashes and salt run into a grayish blue mass, which is the barilla. The best sort is here called sweet barilla.

The sweet barilla examined by Mr. Kirwan was of a bluish color, covered over with a saline powder exceedingly hard, and had a sharp alkaline taste. When broken, it looked black in the fractured part, and visibly contained pretty large pieces of charcoal. To find the proportion of fixed air in this substance, having reduced a quantity of it to fine powder, he poured on an ounce of it a sufficient quantity of marine acid, and found it to lose by the action of this acid eighty grains of its weight; consequently one pound troy of this substance contains 960 grains of fixed air (mixed with a little that had an hepatic smell), that is exactly one-sixth of its weight. Other parcels contained somewhat more, and others somewhat less.

As this substance evidently contained some parts that were soluble in water, and some that were insoluble therein, to discover the weight of each, Mr. Kirwan poured on one pound of it, reduced to fine powder, thirteen pounds of water, moderately hot, successively; this water had previously been boiled and filtered, and tained no other impurity than a slight trace of common salt. This quantity of water was necessary to exhaust all the soluble matter in the barilla. The solutions were taken in six different portions: none of them betrayed the smallest trace of sulphur, nor did the Prussian alkali discover any vestige of iron. By eighteen successive evaporations and crystallisations, he obtained 4881 grains of saline matter, and 2903 of insoluble matter.

It may at first sight appear extraordinary that

the saline matter and the insoluble part should weigh more than the pound of barilla that seemed to afford them; for this amounts only to 5760 grains, and the two former weigh 7784 grains; but it should be considered that these products were obtained not from the barilla alone, but from the barilla and the water in which the salts were dissolved, whose crystals retained a great quantity of it, and also from the air to which the solutions were exposed, and which they absorbed in large proportion. As the quantity of the insoluble matter was subject to no such deceptive appearance, Mr. Kirwan began by examining the weight of that; for this, being subtracted from 5760 grains, necessarily determined the true weight of the saline part; as the state in which the saline part exists in barilla depends in some measure on the earths and charcoal with which it is united, as well as the most advantageous method of using it.

Having therefore dried the insoluble matter for a considerable time, in a low heat, until it appeared as dry as the barilla itself, and found its weight in that state to amount to 2903 grains, or 6·04791 ounces, Mr. Kirwan took one ounce of it, and, drying it in a heat little below redness, found it to lose thirty-eight grains of moisture. Another ounce of the same residuum, being treated with dilute marine acid, lost 125·5 grains of its weight, and this loss expresses the quantity of fixed air contained in it. Another ounce, being calcined in a white heat for about one hour, lost 200 grains of its weight; and, on repeating this experiment, he found the loss amount to 199 grains. Lastly, on the 281 grains which remained after this experiment, he poured dilute marine acid, and found the quantity of fixed air to be 106 grains.

Mr. Kirwan next examined the fixed incombustible part that remained after the above calcination. On the 279 grains of this, which remained after the calcination of an ounce of the insoluble part, he poured a quantity of distilled vinegar, whose specific gravity in the temperature of 62° was 1·008, and digested that residuum therein for sixteen hours in a heat little more than 100°. After edulcoration, and desiccation, the weight of what remained undissolved was found to amount to sixty-three grains. Upon this experiment he reasoned thus: 281 grains of a residuum of this sort contained 106 grains of fixed air, therefore the 279 grains subjected to the vinegar in this experiment must have contained 105·24, which were dissipated by the action of the acid; there remained, therefore, of mere earth only 173·76; but of these sixty-three escaped the action of the acid, therefore there were dissolved 110·76. And as distilled vinegar can act only on calcareous and muriatic earth (the barytic not being excepted), the 110·76 that were dissolved must have consisted of either or both of these, and the undissolved sixty-three grains must have been argillaceous or siliceous. The sixty-three grains, being digested in spirit of salt, left a residuum of 41·3 grains, which, therefore, were siliceous; the remainder, not being precipitable by the vitriolic acid, was consequently argillaceous earth: hence the quantities of these ingredients in 480 grains of the insoluble part of barilla were found to be:—

		In the whole soluble part.
	grains.	grains.
Fixed air . . .	125·5	759
Water . . .	38	229·82
Charcoal . . .	142·5	861·82
Calcareous earth . . .	89·76	542·86
Muriatic . . .	21	127
Argillaceous . . .	21·7	131·23
Siliceous . . .	41·3	249·58
	479·76	2901·31
Error . . .	24	Error 1·69
	480·00	2903·00

We may now return to the soluble part of the barilla, which necessarily amounted to 2857 grains. In the first place, Mr. Kirwan obtained 4213 grains of pure crystallised mineral alkali: but these crystals are known to contain but one-fifth of real alkaline substance, the remainder being fixed air and water of crystallisation; therefore, one pound of barilla contains but 842 grains of pure teal alkali. Besides this, he also obtained 127 grains of a mixture of vegetable and mineral alkali, with a small proportion of extractive matter, and some digestive salt; this mass constantly attracted moisture. These solutions afforded also 125 grains of Glauber's salt, and seventy of common salt; but the Glauber's salt, at least, did not exist in a crystallised form in the barilla; and, as 100 grains of it are reduced to forty-two by expelling the water of crystallisation, no more than fifty-three grains of it can be deemed to have pre-existed in the barilla. Hence the weight of the different ingredients contained in one pound of sweet barilla is as follows:—

Fixed air . . .	960	
Charcoal . . .	861·82	
Calcareous earth . . .	542·86	
Muriatic earth . . .	127	} 1050·67
Argillaceous . . .	131·23	
Siliceous . . .	249·58	
Mineral alkali pure . . .	842	
Mineral alkali impure . . .	250	} 12
Mineral alkali mixed with common salt . . .	127	
Glauber's salt . . .	125	
Common salt . . .	70	
Earth deposited . . .	20	
	4306·49	
Water . . .	1453·51	
Total . . .	5760·00	

Hence we see that the alkaline part of barilla is nearly in a caustic state; for the entire pound of barilla contained but 960 grains of fixed air, and of this quantity 759 were contained in the earthy part. Therefore only 201 grains were contained in the saline part. Now 960 grains of this require for their saturation at least 700 of fixed air, therefore they wanted at least two-thirds

of the quantity requisite to saturate them. Hence bleachers should not use boiling water to extract the saline substance of barilla, for the alkaline part being in a caustic state dissolves part of the coaly matter with which it is united, which sullies the solution, gives it a dark hue, and afterwards is deposited on the linen, and cannot be separated by acids.

Dantzic pearl-ash.—The quantity of fixed air and earth contained in different parcels of this substance is variable; in some ounces the quantity of fixed air was found to amount to 100 grains, in others to 115; and therefore at a medium it may be rated at 107·5 grains, or 1290 grains in one pound troy. The earth remaining after the solution of one pound amounted to twenty grains. After ten evaporations, Mr. Kirwan procured from one pound of this substance 505 grains of tartar vitriolate, the last portions of which contained some digestive salt, and also thirty-six grains of this last containing a portion of tartar vitriolate; about eighteen grains of earth were deposited during the evaporations. The remainder of the pound consisted of the pure alkali. Hence the ingredients in a pound must have been nearly in the following quantities:—

Fixed air	1290
Moisture	414
Digestive salt and ditto	36
Tartar vitriolate	505
Earth	38

	2283	5760
Mere alkali	3477	2283
	5760	3477

Mr. Kirwan considers the following method much more practicable and easy than the preceding, for discovering the alkaline principle in all substances in which it exists. 1st. Procure a quantity of alum, suppose one pound; reduce it to powder, wash it with cold water, and then put it into a tea-pot; pour on it three or four times its weight of boiling water. 2dly. Weigh an ounce of the alkaline substance to be tried, powder it and put it into a Florence flask with one pound of pure water; if the substance to be examined be of the nature of barilla or potash; or half a pound of water if it contain but little earthy matter as pearl-ash; let them boil for a quarter of an hour; and when cool let the solution be filtered into another Florence flask. 3dly. This being done, gradually pour the solution of alum hot into the alkaline solution also heated, a precipitation will immediately appear; shake them well together, and let the effervescence, if any, cease before more of the aluminous solution be added; continue the addition of the alum until the mixed liquor, when clear, turns syrup of violets red; then pour the liquor, and precipitate on a paper filter placed in a glass funnel, the precipitated earth will remain on the filter; pour on this a pound or more of hot water until it passes tasteless; take up the filter and let the earth dry in it until they separate easily, then put the earth into a cup of Staffordshire ware, place it on hot sand and dry the earth until it ceases to stick to glass or iron, then pound it and reduce it to powder in the cup with a glass pes-

tle, and keep it a quarter of an hour in a heat from 470° to 500°. 4thly. The earth being thus dried, throw it into a Florence flask and weigh it, then put about one ounce of spirit of salt into another flask, and place this in the same scale as the earth, and counterbalance both in the opposite scale; this being done, gradually pour the spirit of salt into the flask that contains the earth, and, when all effervescence is over, blow into the flask, and observe what weight must be added to the scale containing the flasks to restore the equilibrium; subtract this weight from that of the earth, the remainder is a weight exactly proportioned to the weight of mere alkali of that particular species which is contained in one ounce of the substance examined; all beside is superfluous matter.

Crystallised soda.—Though it contains only one-fifth of its weight of real alkali, the remainder being water and fixed air, but the proportion of alkali being invariably the same, it is the fittest for a standard with which other substances containing the same sort of alkali may be compared. Mr. Kirwan found that as much of this substance as would contain 480 grains of mere alkali would precipitate 725 grains of earth of alum dried, and consequently that 480 grains of mere mineral alkali precipitate 725 of earth of alum.

Cunnamura kelp.—This is a hard porous black substance, mixed with white and gray spots, it smells sulphureous, and its taste mixed, being that of common salt and alkali. One ounce of it dissolved in marine acid lost twenty-four grains of its weight, which escaped in an aerial form. This air was hepatic. Another ounce dissolved in boiling water left an insoluble residue, which, being heated in a crucible to redness, weighed 165 grains; this residue effervesced with acids, and seemed for the most part calcareous. This solution precipitated twenty-five grains of earth of alum, and therefore contained 16·5 grains of mere alkali. During the precipitation of the earth of alum much hepatic air was emitted, and the earth was sullied by the sulphur, though only a few grains of this can be presumed to be mixed with it.

Strangford kelp.—This substance was much denser, less porous, and in appearance approached more to that of a vitrified mass than Cunnamara kelp; it was at least equally sulphureous. The solution of one ounce of it precipitated only nine grains of earth of alum, and this earth was much more discolored than that precipitated by the preceding kelp. The insoluble residuum of an ounce amounted to 174 grains.

Vegetable alkali.—Mr. Kirwan found that 480 grains of the purest and driest salt of tartar (making allowance for the quantity of fixed air it contained) precipitated 331·5 grains of earth of alum.

Cashup.—The best sort, namely, that marked with the cross arrows, is of a bluish-gray color, exceedingly hard, and of a semivitrified appearance, its smell sulphureous, its taste scarcely alkaline, and does not attract the moisture of the air. With marine acid, one ounce of it afforded thirty-one grains of hepatic air. When dissolved in water the residuum of an ounce was 357 grains of a gray earth, that appeared to be calca-

reous for the most part. The solution itself was of a yellow color and strongly sulphureous. With the solution of alum it did not effervesce strongly, until a good deal was added. The precipitate was of a dirty white, and amounted to sixty-six grains, of which two appeared to be sulphur. Hence its quantity of vegetable alkali is nearly ninety-three grains per ounce.

Common Irish weed ashes.—This was of a loose texture, dark gray color, and salt taste, mixed with charcoal, brick-dust, and other impurities. One ounce of it lost by gentle drying forty-seven grains, and in a red heat seventy-two grains more. Twelve ounces of the undried ashes, being lixiviated, left a residuum, which when dried weighed 4214 grains; the solution was reddish, replete with extractive matter; it afforded a large quantity of digestive salt, and some tartar vitriolate, and very little alkali. Two ounces of the same ashes being gently heated to a slight degree of redness lost 186 grains of their weight. One ounce of this calcined ash being boiled in six ounces of water left a residuum of 344 grains, and consequently contained 136 grains of saline matter; but of this saline matter only 22.4 grains were pure alkali, for the solution precipitated 15.5 grains of earth of alum; an hepatic smell was perceived during the precipitation of the alum, and the earth was of a dirty color.

The following table contains the quantity of mere alkali, in 100 avoirdupois pounds of the substances below-mentioned, by the aluminous test:—

	Mineral alkali.
Crystallised soda	20 lbs.
Sweet barilla	24
Cunnamara kelp	3.437
Do. desulphurated by fixed air	4.457
Strangford kelp	1.25
	Vegetable alkali.
Dantzic pearl-ash	63.33
Clarke's refined ash	26.875
Cashup	19.376
Common raw Irish weed ash	1.666
Do. slightly calcined	4.666

Mr. Kirwan furnishes in his paper a section on the coloring matter of linen yarn and its solvents. Having procured a sufficient quantity of alkaline lie saturated with this coloring matter, or, as the workmen call it, *killed*, and which they are in the habit of throwing away, he found it to be a turbid liquor, of a reddish-brown color, a peculiar taste, and strong smell, affording no sign of either acidity or alkalescence. On five quarts of this liquor he poured two ounces of weak marine acid; there was no effervescence, but a copious deposition instantly took place of a grayish-green color, and the liquor freed from this deposit was of the color of red amber. The next day he drew off the liquor with a syphon, and poured two quarts of pure water on the deposited matter; and, having agitated the whole, suffered this matter again to subside, drew off the water, and added two quarts more; this liquor gave manifest signs of acidity, and continued somewhat reddish. Presuming, that after the addition of so much water, this acidity could

not proceed from the small quantity of marine acid he had used, more especially as the liquor originally contained an alkali, in the saturation of which the greater part of the acid must have been employed, he began to suspect that this lie contained an acid of its own, which was disengaged and separated from the alkali by the marine acid as the more powerful of the two; and hence he reserved the two quarts of liquor, last added, for subsequent experiments. After repeated effusions of cold water, when the characters of acidity were scarcely any longer perceptible, he threw the deposited matter on a filter and suffered it to dry for some time; it was then of a dark greenish color, somewhat clammy like moist clay. He took a small portion of it, and added to it sixty times its weight of boiling water, but not a particle of it was dissolved. The remainder was dried in a sand heat; it then assumed a shining black color, became more brittle, but internally remained of a greenish yellow, and weighed an ounce and a half.

By treating eight quarts more of the saturated lie in the same manner, Mr. K. obtained a further quantity of the greenish deposit, on which he made the following experiments: 1st. Having digested a portion of it in rectified spirit of wine, it communicated to it a reddish hue, and was in a great measure dissolved; but by the effusion of distilled water the solution became milky, and a white deposit was gradually formed; the black matter dissolved in the same manner. 2ndly. Neither the green nor the black matter was soluble in oil of turpentine or linseed oil by a long continued digestion. 3dly. The black matter being placed on a red-hot iron, burned with a yellow flame and a black smoke, leaving a coaly residuum. 4thly. The green matter being put into the vitriolic, marine, and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the latter, but did not seem in the least diminished.

Hence it appears that the matter extracted by alkalies from linen yarn is a peculiar sort of resin, different from pure resins only by its insolubility in essential oils, and in this respect resembling lacs. He now proceeded to examine the power of the different alkalies on this substance; eight grains of it being digested in a solution of crystallised mineral alkali, saturated in the temperature of 60°, instantly communicated to the solution a dark brown color; two measures (each of which would contain eleven pennyweights of water) did not entirely dissolve this substance. Two measures of the mild vegetable alkali dissolved the whole. One measure of caustic mineral alkali, whose specific gravity was 1.053, dissolved nearly the whole, leaving only a white residuum. One measure of caustic vegetable alkali, whose specific gravity was 1.039, dissolved the whole. One measure of liver of sulphur, whose specific gravity was 1.170, dissolved the whole. One measure of caustic volatile alkali dissolved also a portion of the matter. See BLEACHING.

M. Hermbstaedt has furnished the following method of preparing colors for dyeing linen goods, which may easily be washed out or bleached and replaced by others. They are

much used in Germany, where they are called *waschfarben* or washing colors. The base is a good white starch, which may be combined with any color whatever, in such a manner as to form a compound, that can be dissolved in warm water without being decomposed. But although starch forms the base of all these colors, a particular process is necessary to prepare each of the different coloring matters that are to be combined with it, which we shall give as follows:—

1. *Blue*.—Grind some indigo of Guatimala to an impalpable powder; then pour four ounces of burning oil of vitriol into an earthen pan, and put to it an ounce of the pulverised indigo, by degrees, and always in small quantities; while the indigo is being thus incorporated with the oil of vitriol, the mixture must be well stirred at each fresh addition of the powder with a stone pestle, until the whole liquid mass becomes of a uniform blackish blue color. By thus mixing indigo with oil of vitriol the mixture heats itself, exhales a sulphurous smell, and a slight fermentation will be perceived. As soon as the fermentation ceases, the vessel must be closely covered, and placed for twenty-four hours in a situation moderately warm, in order to give time for the acid to dissolve the indigo entirely.

When the dissolution is effected, the liquid must be diluted with ten times its weight of pure water; after which it is exposed to the fire in a copper vessel, until it is nearly as hot as boiling water. Then soak it in some flocks of wool well bleached, or pieces of white wool, in the proportion of eight ounces of wool to half an ounce of the dissolved indigo; expose the whole for twenty-four hours to a moderate fire of about 150° of Fahrenheit's thermometer. The wool acquires a very deep blue dye, almost black; and the remainder of the liquid is almost entirely deprived of the blue coloring matter, and appears of a dirty green color. In this manner the wool absorbs the blue coloring matter of the indigo, by separating it from the heterogeneous particles that were combined with it.

The wool that has been thus dyed is put into a sieve over a tub, and some pure river water poured on, being kneaded at the same time, until the water comes off quite clear and colorless; thus the heterogeneous and dirty parts are separated from the indigo, and the pure blue coloring matter remains with the wool. When this operation is terminated, a quantity of river or rain water, equal to forty times the weight of the indigo and oil of vitriol, is boiled in a boiler; in this water is dissolved as much crystallised natron as equals the quantity of indigo employed; the dyed wool is then plunged into it, and boiled until it has nearly lost all its color. The wool when it comes out of the boiler is a blue gray; the liquid remains of a fine deep blue, and contains the coloring matter of the indigo pure and dissolved.

If, for instance, an ounce of indigo is dissolved in oil of vitriol, and the liquid evaporated until the weight is reduced to four pounds and a half, then strained through a linen cloth, in order to separate the foreign particles that may be mixed with it, after which, if this blue dye be left to cool, it is then in a proper state to be em-

ployed as a coloring matter to give a blue color to starch.

If a deep blue is desired, the proportions must be half an ounce of indigo to a pound of starch; for a middling color, a pound and a half of starch to the same quantity of indigo; and, for a light blue, two pounds of starch to the same. The starch must be put into a bowl, the blue dye poured on it, and the whole well rubbed together until the starch be completely divided, and uniformly combined with the dye. Lastly, the mixture must be left at rest, until it acquires the consistency of a fine thin jelly; it is then dried in a warm air, and put away for use.

2. *To prepare a blue color with prussiate of iron*.—A blue color, similar to the preceding, may be prepared by employing, instead of indigo, prussiate of iron, or Berlin blue. The last mentioned must be of the best quality, and it is rubbed with water in a mortar until it is so far combined with it that it will not easily separate; afterwards the blue matter is left to deposit, the water is decanted off, and the matter is triturated with the quantity of wet starch that is necessary to make the shade of blue desired. This color, which is very fine, is dried, and bears the action of the sun and air better than the preceding. It must be observed, however, that when the cottons that have been dyed with this color are washed with this soap, it always leaves a yellowish tint in the water.

3. *Citron-yellow*.—Weld, saw-wort, and turmeric, are employed in preparing this color. One pound of the two first substances, or half a pound of the turmeric, if that root is preferred, are boiled with twelve pounds of water, in a copper boiler, until the liquid is reduced to a pound, which is then strained through a linen cloth. In this clear liquid two ounces of alum are dissolved, the solution is suffered to cool, and two pounds of white starch are mixed with it, and rubbed until all its particles are well combined with those of the color. This compound is then dried in the air.

4. *Orange color*.—Bixa orellana is preferred for this color: an ounce of it is pulverised with half an ounce of pure potash; some river water is poured on it, and this mixture is digested in an earthen vessel, closely covered, for four hours, at a temperature of 185° of Fahrenheit, and occasionally shaken.

The liquid obtained by this process is of an orange color, which is drained through linen, suffered to cool, and then incorporated with two pounds of starch. The whole is afterwards dried in a warm or temperate air.

5. *Green*.—This color is composed of blue and yellow: in order to obtain it, a part of the indigo dye, described at No. 1, and as much of the yellow dye of No. 3, are mixed together until the desired color is produced, which may be known by trying it on paper. A pound of this mixed dye is dissolved with an ounce of alum; when the solution is cold two pounds of white starch are mixed, and well incorporated with it, after which it is dried.

In this manner different shades of green can be obtained, according to the proportions in which the blue and yellow dyes are mixed.

6. *Olive*.—This color is prepared by mixing the indigo dye No. 1, with the bixa orellana, No. 4, until the desired shade is obtained; the necessary quantity of starch is then added, and the mixture dried.

7. *Red*.—This is prepared from Brasil wood or cochineal; if the first be preferred, a pound of scrapings of this wood must be boiled in a tin copper cauldron, with twelve pounds of rain or river water, until the whole is reduced to two pounds. It is then strained through linen. Afterwards two ounces of alun are dissolved in three ounces of boiling water, to which are added six ounces of the decoction of Brasil wood, and the whole is left to cool. To this mixture three pounds of white starch are added, and well incorporated; then the remainder of the decoction of Brasil wood is poured on, and the mixture is stirred until it acquires the consistency of a thin jelly, when it is dried in the air.

8. *Crimson*.—Half an ounce of pulverised cochineal is tempered with water, and put into a tin vessel, containing two pounds of boiling water. When the whole is well mixed, it must continue gently boiling until the quantity of liquid is reduced to a pound: it is afterwards strained through linen or a paper filter. In this colored liquid half an ounce of alun is dissolved; and when it is cold two pounds of starch are well incorporated with it; it is then left to dry in the air at a mild temperature.

Besides these two colors, other shades of red may be obtained:—

(1.) By adding, instead of the alun, half an ounce of tin dissolved in aqua regia, to a pound of the cochineal or fernambouc dye.

(2.) By mixing either of these dyes with a decoction of weld or turmeric, by which means yellow reds and coquelicot may be produced.

(3.) By mixing them in different proportions with the blue dye, this mixture will produce different shades of violet and purple.

9. *Violet*.—Half a pound of scrapings of log-wood must be boiled with six pounds of water in a tin vessel, until the liquid is reduced to a pound and a half. This decoction is strained through linen, or filtered through paper. An ounce of tin dissolved in aqua regia is then added to it, two pounds of starch incorporated with it, and left to dry in mild air. In this manner the colors and shades may be multiplied and diversified in a thousand ways by mixing the above decoction in different proportions, or by adding to it other coloring substances in order to obtain dyes that may be combined with the starch.

When any of these colors are used to dye wearing apparel, furniture, &c., any quantity may be taken and tempered with fresh water, and afterwards dissolved in boiling water: into this the stuff must be plunged; which, with well rubbing, takes the desired color, and acquires also additional body or solidity. See DYEING.

Mr. Shotwell obtained a patent, in 1807, for a machine for bleaching, washing, and cleansing linen. It consists of an oblong wooden box of about three feet and a half in length, fourteen inches wide, and about fourteen inches deep, made perfectly water-tight, excepting a small

hole through the bottom near to one end, to draw off the water when done with, which hole is at other times stopped up by a bung or any other contrivance. To this box legs are affixed, so as to raise it about three feet from the ground; it is covered over with boards laid cross-ways about four inches and a half at each end, and which may be made to project outwards to any extent, as also over each side so as to form a table. The remaining open space is covered with two flaps, excepting a portion of about nine-eighths of an inch; one of these flaps is hung with hinges to the outward or back side, so as to form a door to lift up; the other is simply laid in grooves, and fastened down by wooden bolts. Into the open space between the boards, the washing implement, represented in figs. 6 and 7, is introduced; and to the top of this a lever is attached in the manner shown at B in figs. 8 and 9; though it is evident, the patentee states, that any other mode of propelling the washing implement may be employed, or the lever may be attached in any other way.

Instead of having the washing-implement on the above plan, the box may be entirely covered over with boards, flaps, or doors, as before mentioned; and pieces of wood may be nailed to the inside, so as to form ridges about an inch and a half from the top, on which the washing-implement may be suspended and made to slide; the whole of the upper part will in this case be needless, and the lower part, which will be in the box, is to be affixed to a lengthened piece of wood C, fig. 8, which is to be brought through a hole made in the end of the machine, opposite to that at which the lever B is placed. This lengthened piece of wood is connected with the lever in the manner shown by the dotted lines C D in fig. 8.

The foul linen to be washed by this machine is evidently to be placed on each side of the implement, which is to be forced backwards and forwards by the lever, as before described.

If it be convenient to admit steam into the machine, the water therein will be kept at a proper heat, and the linen will be whiter than in the usual way of washing. The steam may be introduced into the washing-machine by means of a pipe communicating with a boiler.

Fig. 6 exhibits a side view of the washing-implement.

Fig. 7 a front view of the same, or that part which faces the end of the machine.

Fig. 8 is a side view of the apparatus complete. A, the oblong box, with small inclinations at each end, as shown by the dotted lines *aa*, which cause the linen to turn more about than they otherwise would, when the washing-implement approaches them. B shows one way of connecting the lever with the implement, and the dotted lines C D another. E is a mortise to support a tenant board, on which the lever B works; it is more clearly shown in fig. 9 which is an end view.

Mr. Shotwell has constructed another apparatus for the same purpose, which it may be advisable briefly to examine. Instead of making an oblong box, a barrel is formed, which is placed horizontally on axes at each end, which

are made to turn in friction-boxes. The barrel is placed on a convenient framing, as may be seen in figs. 10 and 11, to which is generally attached a vessel, immediately under the washing-barrel A, to receive the dirty water from the barrel, in which there is a hole B to permit its escape into the vessel D. In this barrel a hole C is made sufficiently large to put in and take out the linen, &c., and which is stopped up with a bung when in use. On the inside of this barrel one or more ribs is affixed, as in the common horizontal barrel-churn; and when steam is to be employed, as in the apparatus described, it must be introduced through one of the axes, which must be perforated for that purpose: the other axis should also be perforated to permit the escape of any superabundance.

Mr. Weise, of Tooley Street, has taken out a patent for making cloth waterproof. Among the materials enumerated by the patentee are, fur, flax or hemp, carded silk, and feathers. The proportions of these are to be five pounds of the finer furs, two pounds and a half of the wool, two pounds of the flax, one pound of the carded silk, and three-quarters of a pound of the feathers. These materials are to be divided into portions of about two ounces each, and to be passed through a fine carding engine by one portion at a time, the fine fur being first laid or bowed on the roller cloth of the engine, which will cause it to lie on the outside of the carded flake. After being thus carded, the materials are to be drawn, roved, and spun, like cotton, the management directed for them being the same as is used for that substance.

The yarn spun is to be of two sorts, one fine, for the warp, and the other coarser and softer, for the weft. It is then to be woven in a loom of from eight to twelve lambs, and a proportional number of treadles. The fine yarn forming the warp is to be kept at the back of the cloth, and the soft weft in the front, by the means well known to weavers, and similar to those used in weaving diapers and velvets.

When the cloth is wanted to be made waterproof, a composition is to be prepared of equal portions of shell-lac, caoutchouc, mastic, gum animi, and sandarac; by cutting the caoutchouc into very small shreds, and pounding the gums and lac very fine, and then dissolving them in ether and spirits of wine, or spirits of turpentine. Into this composition the fine skeins for the warp are to be dipped, and then to be gently pressed or left to drain, and to be hung up to dry; and, when dry, are to be stretched in the loom, where, instead of the common sizing, the composition above stated is to be used.

After the cloth is woven, the fur or nap is to be drawn forward on its front by teazles or cards, and a hot smoothing iron is to be passed over its back, to cause the composition to sink into it, and close the interstices.

This cloth, when intended for hats, is to be laid over linings or moulds, on hat blocks, of the same materials usual for those of silk hats, and to be managed in the same manner. For wearing apparel the cloth is to be chiefly made of Saxon wool and flax, managed as before mentioned; and when cloth with a pile, like

plush or velvet, is wanted, it is to be woven in a velveteen loom, and then to be cut in the usual manner.

A few facts connected with the history of weaving may now be introduced.

The combined arts of spinning and weaving are among the first essentials of civilised society, and we find both to be of very ancient origin. The fabulous story of Penelope's web, and still more the frequent allusions to this art in the sacred writings, tend to show, that the fabrication of cloth from threads, hair, &c., is a very ancient invention. It has, however, like other useful arts, undergone a vast succession of improvements, both as to the preparation of the materials of which cloth is made, and the apparatus necessary in its construction, as well as in the particular modes of operation by the artists. Weaving, when reduced to its original principle, is nothing more than the interlacing of the weft or cross threads into the parallel threads of the warp, so as to tie them together, and form a web or piece of cloth. This art is doubtless more ancient than that of spinning, and the first cloth was what we now call matting, viz. made by weaving together the shreds of the bark, or fibrous parts of plants, or the stalks, such as rushes and straws.

This is still the substitute for cloth amongst most rude and savage nations. When they have advanced a step farther in civilisation than the state of hunters, the skins of animals become scarce, and they require some more artificial substance for clothing, and which they can procure in greater quantities. Nevertheless, some people are still ignorant of the art of weaving; for the cloth made in the islands of the South Sea appears to be made by cementing or glueing the shreds together, rather than by weaving. From the description given by captain Cook, and other circumnavigators, and from the specimens which have been brought to Europe, their cloth, or rather matting, is in general produced by cohesion of the parts, rather than texture. This assimilates it more to the ideas which we attach to paper or paste-board, than those which we form of cloth.

When it was discovered that the delicate and short fibres, which animals and vegetables afford, could be so firmly united together by twisting as to form threads of any required length or strength, the weaving art was placed on a permanent foundation. By the process of spinning, which was very simple in its origin, the weaver is furnished with threads far superior to any natural vegetable fibres in lightness, strength, and flexibility; and he has only to combine them together in the most advantageous manner.

The art of weaving cloth has been so extensively applied in almost every civilised country, and the knowledge of its various branches has been derived from such a variety of sources, that no one person can ever be practically employed in all its branches; and, though every part bears a strong analogy to the rest, yet a minute knowledge of each of these parts can only be acquired by experience and reflection.

We may now briefly examine the origin of the linen manufactory in Ireland. In the year

1633 lord Wentworth, an austere, imperious, but active and sagacious nobleman, entered into office as chief governor. He was a tyrant, but his tyranny was tempered with wisdom. Sensible how much the power and glory of a monarch depend on the prosperity of his people, he was so assiduously attentive to the peace, intellectual improvement, and industry of the Irish, that, though individuals often felt the arrogance of his temper, the nation in general had reason to be grateful for the benefits arising from the vigor of his administration. Protected by a strictness before unknown in the execution of English law, unusual numbers, and with unusual attention, applied their thoughts to pursuits of industry; the consequences of which appeared in the rising value of land, the augmented quantity of products for exportation, and such an increase of commerce, that the shipping of Ireland was multiplied a hundred fold. For the encouragement of traffic, this deputy, so zealous for the promotion of the power and revenue of his master, used his influence for the abolition of oppressive duties on the importation of coals and horses into Ireland, and on the exportation of live cattle.

By Wentworth's endeavours, a manufacture of linen cloth was established in Ulster; a recent fabrication of woollen drapery was discouraged, lest it should come in competition with that of England, for the purpose that Ireland should be dependent on that country for the clothing of its inhabitants, and consequently less prone to a political separation; to make amends for this injustice, the deputy exerted himself so strenuously for the encouragement of linen, that he took a share in the enterprize, at the expense, according to his own statement, of £30,000, from his private fortune; as flax had long been known to thrive in this country, and many of the women being spinners, hopes of success were early conceived. Flax-seed was brought from Holland; weavers from several parts of the Low Countries, and from France; looms were fabricated, and regulations formed for the prevention of defects in the cloth by fraud or negligence: experience has proved the propriety of the plan, since this manufacture, notwithstanding its interruption in its infancy, by a desolating civil war, became in time the principal support of the wealth of Ireland.

In Ireland, every bleacher must stamp his own name on the end of every web; hence it can always be ascertained, by mere inspection, where the bleaching has been performed. Again, should any goods be improperly bleached, so that the texture is injured, the bleacher is liable to be compelled to take back the whole of them, and pay every expense of carriage, however far they may have been conveyed from the spot where they were finished. In this case, the bleacher is also subjected to a considerable fine. So certain is the infliction of this penalty, in case of a complaint being properly lodged against a delinquent, that some years ago, when the bleaching process was not conducted with that care with which it is at present, several persons actually travelled through many of the counties of England and Scotland for the purpose of collecting

from the mercers all such damaged Irish linens, and for which they paid good prices, in order to be entitled to receive the fines.

The best regulation may, however, be superseded and often evaded. Accordingly it is well known that many hundred thousands of pieces of calicoes are made and finished in Lancashire, and stiffened in a peculiar way, to imitate the Irish linens, particularly those made at Colerain, and that they have the name of this place stamped upon them.

It is notorious that a kind of linen thread made at Paisley, in Scotland, and known by the name of nuns' thread, has the preference, and is the best for use. In consequence of the character which this thread has acquired, the Irish have begun a similar manufacture, and scruple not to usher theirs into the market under the sanction of a stamp bearing the name of Paisley.

In like manner, an article called Inkle, and some species of thread resembling that which is made in Holland, are now manufactured in large quantities in Scotland, and sold under a Dutch stamp; the method of making these articles having been stolen from Holland, and brought into Scotland half a century ago. Thds, self-interest is apt to be the leading motive with mankind in all nations.

The linen trade of this country is regulated by several statutes.

No person shall put to sale any piece of dowlas linen, &c., unless the just length be expressed thereon, on pain of forfeiting the same, 28 Hen. VIII. cap. 4. Using means whereby linen-cloth shall be made deceitfully incurs a forfeiture of the linen, and a month's imprisonment. Stat. 1 Eliz. cap. 12. Any persons may set up trades for dressing hemp or flax, and making thread for linen-cloth, &c. 15 Car. II. cap. 15.

By 43 Geo. III., c. 69, all former duties on linen-cloth, silks, cottons, and calicoes are repealed; and in lieu thereof other duties are imposed upon all goods which shall be printed, stained, painted, or dyed in Great Britain, according to a schedule annexed to the act: and, by 50 Geo. III. c. 26, certain export duties are imposed; the said duties to be paid by the printer, stainer, painter, or dyer. By 49 Geo. III., c. 98, certain duties and customs are imposed upon French linens (or lawns). By 43 Geo. III., c. 69, every calico printer, and every printer, painter, or stainer of linens, cottons, or stuffs shall pay annually for a license £10. The printing or staining of calicoes must be for exportation; because by 7 Geo. I., stat. 1, c. 7, the use of printed, painted, stained, or dyed calico for wearing apparel is prohibited, on pain of £5 to the informer, on conviction: and a person offering such for sale, unless for exportation, forfeits £20, half to the informer and half to the poor. This prohibition, however, does not extend to calicoes dyed wholly blue: and it shall be lawful to use stuff made of linen yarn and cotton wool manufactured, and printed or painted in Great Britain, provided the warp thereof be wholly linen yarn. 9 Geo. II., c. 4. By 14 Geo. III., c. 72, it is enacted that no greater duty shall be paid for stuffs made of raw cotton wool within this kingdom than 3^d. a yard, 43 Geo.

III., c. 69, and that any person may use the same in apparel or otherwise: and every piece is to have three blue stripes in both selvages, and to be stamped at each end with a stamp provided by the officers of excise; and, instead of the word calico, used for foreign calicoes, each piece shall be marked with the words *British Manufactory*. If stuffs made wholly of cotton, and printed, painted, stained, or dyed stuffs (muslins, neck-cloths, and fustians excepted), without such mark shall be exposed to sale, they shall be forfeited, and £50 for each piece. If any person shall counterfeit such stamp, or knowingly sell such stuffs with a counterfeit stamp, he shall be guilty of felony without benefit of clergy. If any person shall import any calicoes, muslins, or other stuffs made of linen yarn only, or of linen yarn and cotton wool mixed, or wholly of cotton wool, in which shall be woven in the selvedge any such blue stripe, he shall forfeit the same and £10 for each piece. Every such printer, painter, stainer, or dyer, shall give notice in writing, at the next office, of his name and place of abode, and where he intends to work, on pain of £50. 10 Anne c. 19; 25 Geo. III., c. 72. By 1 Geo. II., stat. 2, c. 34, any person undertaking to print, paint, &c., any silks, linens, or stuffs, at any other place than the place of his usual residence or exercise of his trade, shall first make entry of the place, and pay the duties, on pain of £50, and forfeiture of the goods. Officers may enter at all times, by day or night, to take account, &c., and the penalty of obstructing the officer in the execution of his duty is £200. 10 Anne c. 19; 25 Geo. III., c. 72. Goods shall be entered once in six weeks on oath before the collector or supervisor, on pain of £50. 10 Anne c. 19. No person shall begin to print, stain, paint, or dye any goods before they have been measured and marked, on pain of forfeiting the same, and also £20 for every piece. 25 Geo. III., c. 72. If any printer shall wilfully cut out or deface such frame-mark, he shall forfeit £50. Concealing goods, or avoiding duty, incurs a forfeiture of £50; and all goods found in a place of which no notice has been given, or the value thereof, shall be forfeited. 10 Anne c. 19; 25 Geo. III., c. 72. Nor shall goods be kept in unentered places on pain of forfeiting £50, and the goods. 20 Geo. III., c. 72. Within six weeks the duties shall be cleared, on pain of forfeiting double. 10 Anne c. 19. Nor shall they be removed before the officer has taken account of them and stamped them, on pain of £50, and seizure. 10 Anne c. 19; 25 Geo. III., c. 72. Goods surveyed shall be kept separate from those unsurveyed, on pain of £50; and goods unstamped may be searched for and seized. 10 Anne c. 19; 25 Geo. III., c. 72. The person in whose custody such goods are found shall forfeit £100. 5 Geo. III., c. 11; 27 Geo. III., c. 31.

Calicoes, &c., that shall not have three blue threads in the selvedge, shall be deemed foreign calicoes; and, on being printed or dyed, shall be marked at each end with the words *'foreign calicoes for exportation;'* and every dealer who shall have any such goods in his custody (except dyed throughout of one color), or any stuffs

made wholly of cotton wool woven in Great Britain, commonly called *'British manufactory,'* (muslins, neckcloths, and fustians, excepted), not having such blue threads, shall forfeit £200, and every such piece found in his custody. 25 Geo. III. c. 72. The owner or printer of any piece or remnant of cossac, or foreign muslins and calicoes, shall, before they be presented to the officer, mark the same at both ends with a frame-mark, containing his name and place of abode, and also the name by which such goods are commonly known (except such as are dyed throughout of one color), on pain of forfeiting £10 for every piece or remnant. The owner or printer of any linens or stuffs made of cotton mixed, or wholly of cotton wool woven in Great Britain, called *'British manufactory or muslins,'* shall mark the same at both ends (fustians, velvets, velverets, dimities, and other figured stuffs, excepted) with a mark, containing his name and place of abode, and the name and quality of such goods, with the ready-money price thereof, before the same are presented to the officer in order to be printed or dyed, on pain of forfeiture, and seizure, and £20; and, if any such piece be marked at a less price than the real value, the same may be seized and forfeited, and the owner shall forfeit £20. If the frame-mark be defaced, the same shall be renewed on notice; but if any person shall counterfeit or forge any frame-mark, he shall forfeit £100; and, if any person counterfeit the stamp, it is felony without benefit of clergy. 25 Geo. III. c. 72; 27 Geo. III. c. 31. If any person shall knowingly sell any of the goods with a counterfeit stamp, he shall forfeit £100, and stand two hours in the pillory. 10 Anne, c. 19; 13 Geo. III. c. 56; 25 Geo. III. c. 72. By 27 Geo. III. c. 31, if any person shall knowingly sell any such goods with counterfeit stamp, thus intending to defraud his majesty, he shall be guilty of felony without benefit of clergy. Every person who has paid the duties, or bought the goods of any person who has paid the duties, may export the same, and shall be allowed all the duties in drawback, as set forth in 43 Geo. III. c. 69, Sched. C., on conforming to certain prescribed conditions. 25 Geo. III. c. 72; 25 Geo. III. c. 74. By the 4 Geo. III. c. 37, which establishes the corporation of the English Linen Company for making cambrics and lawns, it is enacted that the commissioners of excise, where there shall be a manufactory of cambrics or lawns, or of goods known under that denomination, shall appoint the supervisor or other officer to seal the same, for which they shall have such fee as the commissioners shall appoint; the manufacturer to give notice in writing to the officer of the finishing of every piece, before it is taken out of the loom, who shall seal the same at both ends; on pain that such manufacturer, taking the same out of the loom without having given such notice, and having the same sealed as aforesaid, shall forfeit £5; and every such piece shall be forfeited, and may be seized by any officer of the customs or excise; and the officer, with convenient speed after notice, shall mark and also number each piece; and make entry in writing, in books to be provided at the expense of the manufacturer,

of the number set to each piece, the length thereof, and the number of threads in the warp, on pain of £10. If the officer shall mark any not made in England, or after the same is taken out of the looms, he shall forfeit £50 for each piece to him who shall sue, and forfeit his office, and be incapacitated to hold any other office of trust under the crown. If any person shall offer to the officer any bribe, he shall forfeit £50; and if he shall by bribery, or otherwise, prevail upon the officer to commit such offence, he shall forfeit £100, and stand in the pillory two hours. And the officer shall yearly, in the month of June, transmit to the commissioners an account of all goods which he shall have stamped, and a copy of the entries made, on pain of dismissal; and he, or his executors, shall deliver up the seals, on demand from the commissioners, on pain of £200. Cambrics and lawns made in England, found unstamped, shall be forfeited, and may be seized by any officer of the customs or excise, and, after condemnation, shall be sold; and every person who shall sell, or expose to sale, or have in his custody for that purpose, any cambrics or lawns made in England, unmarked, shall forfeit £200: such goods not to be sold, or worn in this kingdom, but to be exported, and to be sold only on condition of exportation. Nor shall they be delivered out of the warehouse until bond be given, to the satisfaction of the collector, in double penalty of the goods, that

the same shall be exported, and not relanded. To counterfeit the seal appointed by this act, or import any foreign cambrics or lawns having such counterfeit mark thereon, or expose the same to sale, knowing the stamp thereon to be counterfeited, is felony without benefit of clergy. All goods condemned in pursuance of this act, and all pecuniary forfeitures (not otherwise directed), shall be sued for and recovered in any of his majesty's courts, in the name of the attorney-general, or of such officer as aforesaid; and applied, after deduction of charges, half to the king, and half to the officer seizing, informing, or suing, according to the directions of this act. The penalties may be sued for, levied, and mitigated, as by the laws of excise, or in the courts at Westminster; and employed half to the king, and half to him that shall discover, inform, or sue. 10 Anne, c. 19; 24 Geo. II. c. 40; 25 Geo. III. c. 72. All utensils and instruments for printing, painting, staining, or dyeing such goods, in custody of the said person, or any other, shall be liable to all arrears of the duty, and to all penalties concerning the same, in like manner as if such person was the lawful owner. 10 Anne, c. 19; 25 Geo. III. c. 72; 28 Geo. III. c. 37.

A few statistical tables, illustrative of this branch of our manufacture, must conclude our article. We shall commence with an enumeration of

The species and quantities of FOREIGN LINENS imported and exported from GREAT BRITAIN and IRELAND, in the year ending 5th of January, 1826.

COUNTRIES FROM WHICH IMPORTED.	Plain of Germany, Silesia, &c.	Plain of Russia.	Plain of Nether-lands.	Can-vas, Hes-sen.	Can-vas, Pack-ing, or Spruce.	Hinder-lands and Brown.	Dril-lings and Pack Duck. The following is an account of the number of yards of linen cloth on which duties of excise have been paid in the year ending 5th of January, 1826, for painting and printing linen both respectively, with the rates of duty paid per square yard.

Linen cloth painted at 3½d. per square yard.	Linen cloth printed at 3½d. per square yard.
Yards. 554,721	Yards. 1,378,356

LING, *n. s.* Isl. and Goth. *ling*; Dan. *lyng*. Heath; brake. The former sense is retained in the northern counties; yet Bacon seems to distinguish them.

Heath, and *ling*, and sodges.

Bacon's Natural History.

LING, *n. s.* Belg. *linghe*; Swed. *lång*. A kind of sea fish.

When harvest is ended, take shipping, or ride, *Ling*, salt fish, and herring, for Lent to provide.

Tusser.

Our English bring from thence good store of fish.

but especially our deepest and thickest *ling*, which are therefore called island *lings*. *Abbot.*

LING. See *GADUS*.

LINGELBACH, or **LINGELBACK** (John), an excellent painter, born at Franckfort on the Maine, in 1625. He learned the art in Holland, but perfected himself at Rome; where he studied till 1650, when he settled at Amsterdam. His usual subjects are fairs, mountebanks, sea-pieces, and landscapes, which he executed well, and enriched with antiquities. His sea-fights are full of expression. He had also great readiness in painting figures and animals, and was employed by other artists to adorn their landscapes with such objects. He died in 1687.

LINGEN ISLE, an island in the Eastern Seas, of irregular figure and situated off the north-east coast of Sumatra. It is fifty miles in length, and thirty in breadth, and is remarkable for a mountain in its centre, terminating in a fork, which the seamen have distinguished by the name of *Ass's Ears*. It is much frequented, and indeed possessed by Malay pirates. The equinoctial line passes through it.

LINGER, *v. n. & v. a.* } Sax. *lmg, leng, long.*

LINGERINGLY, *adv.* } To remain (i. e. stay long); particularly to remain in pain, languor, illness, or suspense. Generally used respecting a culpable or painful delay; barbarously used by Shakspeare as an active verb, or in the sense of to protract; draw out: lingeringly is tediously; in a delaying manner.

And while he *lingered*, the men laid hold upon his hand; and they brought him forth. *Gen. xix. 16.*

Let order die,

And let this world no longer be a stage

To feed contention in a *lingering* act. *Shakspeare.*

We have *lingered* about a match between Anne Page and my cousin Slender, and this day we shall have our answer. *Id.*

She doth think, she has strange *lingering* poisons. *Id.*

I can get no remedy against this consumption of the purse. Borrowing only *lingers* and *lingers* it out, but the disease is incurable. *Id.*

Perhaps thou *lingerest*, in deep thoughts detained Of the enterprise so hazardous and high. *Milton.*

Of poisons, some kill more gently and *lingeringly*, others more violently and speedily, yet both kill. *Id.*

Not accompanied with so acute torments, nor with so *lingering* pains, nor with so utter a ruin as might have been inflicted. *Barrow.*

Should not a *lingering* fever be removed,
Because it long has raged within my blood?

Dryden.

Ye brethren of the lyre, and tuneful voice,
Lament his lot; but at your own rejoice.

Now live secure, and *linger* out your days;
The gods are pleased *alone* with Purcell's lays. *Id.*

Like wretches, that have *lingered* long,
We'll snatch the strongest cordial of our love. *Id.*

Your very fear of death shall make ye try
To catch the shade of immortality;
Wishing on earth to *linger*, and to save
Part of its prey from the devouring grave. *Prior.*

Better to rush at once to shades below,
Than *linger* life away, and nourish woe.

Pope's Odyssey.

Sir,—For some months past I have been *rambling* over the country; but I am now confined with some *lingering* complaints, originating, as I take it, in the stomach. *Burns.*

Straight be thy course: nor tempt the maze that leads

Where fell Remorse his shapeless strength conceals,
And oft Ambition's dizzy cliff he treads,

And slumbers oft in Pleasure's flowery vales.

Nor *linger* unresolved. *Beattie.*

LING'ET, or } Fr. *linget*, iron; Span. *ingot.*

LIN'GUET, *n. s.* } A small piece of metal.

Other matter hath been used for money, as, among the Lacedemonians, iron *linguets* quenched with vinegar, that they may serve to no other use. *Camden.*

LING'O, *n. s.*

LINGUA'CIOUS, *adj.* } Port. *lingua*, from
LINGUADENT'AL, *adj.* } the Lat. *lingua*, the
} tongue, the origin of
} the other words. **LIN-**

GUACIOUS is full of tongue; loquacious; talkative: linguadental, Lat. *lingua* and *dens*, uttered by the joint action of the tongue and teeth: linguist, a professor of languages, or one skilled in various languages.

Though a *linguist* should pride himself to have all the tongues that Babel cleft the world into, yet, if he had not studied the solid things in them, as well as the words and lexicons, he were nothing so much to be esteemed a learned man, as any yeoman or tradesman competently wise in his mother dialect only. *Milton.*

The *linguadentals*, *f, v*, as also the *linguadentals*, *th, dh*, he will soon learn.

Holder's Elements of Speech.

Our *linguist* received extraordinary rudiments towards a good education. *Addison's Spectator.*

I have thoughts to learn somewhat of your *lingo*, before I cross the seas. *Congreve.*

This then, if fostered by the hand of a skilful *linguist*, this science might perhaps, in time, come nearer than any other to realize the extravagant idea of the ingenious but romantic Bishop Wilkins, of an universal language. *Canning.*

LINGONES, an ancient people of Gallia Belgica, who inhabited part of Champagne, now in the department of the Upper Marne. They were conquered by Julius Cæsar, and made tributaries to Rome. They afterwards emigrated into Italy, and settled on the Adriatic, near the Alps.

LING-TAO, a city of China of the first rank, in the province of Chen-si, in a fertile territory, abounding with gold, corn, fruits, cattle, tigers, wild bulls, &c.: 672 miles W. S. W. of Peking. Long. 121° 20' E. of Ferro, lat. 35° 22' N.

LIN'IMENT, *n. s.* Fr. *liniment*; Lat. *linimentum*. Ointment; balsam; unguent.

The nostrils, and the jugular arteries, ought to be anointed every morning with this *liniment* or balsam. *Harey.*

The wise author of nature hath provided on the rump two glandules, which the bird catches hold upon with her bill, and squeezes out an oily pap or *liniment*, fit for theunction of the feathers. *Ray.*

A **LINIMENT**, in pharmacy, is somewhat thinner than an unguent, and thicker than an oil. used for anointing different parts of the body. The materials proper for composing liniments are, fats, oil, balsams, and whatever enters the composition of unguents and plasters.

LINK, *n. s. & v. a.* Teut. *gelenke*; Dan. and Isl. *lanke*; Swed. *lank*. A part or ring of a

chain; a loop; any thing connected in its parts by loops or rings, and any single part of such thing: to connect together; enchain; unite; or concatenate.

But fair Clarissa to a lovely frere
Was *linked*, and by him had many pledges dear.

Fucrie Queene.

They make an offer of themselves into the service of that enemy, with whose servants they *link* themselves in so near a bond.

Hooker.

These things are *linked*, and, as it were, chained one to another: we labour to eat, and we eat to live, and we live to do good; and the good which we do is as seed sown, with reference unto a future harvest.

Id.

The Roman state, whose course will yet go on
The way it takes, cracking ten thousand curbs
Of more strong *links* asunder, than can ever
Appear in your impediment.

Shakspeare. Coriolanus.

They're so *linked* in friendship,
That young prince Edward marries Warwick's daughter.

Shakspeare.

Blood in princes *linked* not in such sort,
As that it is of any power to tye.

Daniel's Civil War.

God has *linkt* our hopes and our duty together.
Decay of Piety.

I feel

The *link* of nature draw me; flesh of flesh,
Bone of my bone thou art.

Milton's Paradise Lost.

Descending tread us down,
Thus drooping; or with *linked* thunderbolts
Transfix us to the bottom of this gulph.

Milton.

Married to immortal verse,
Such as the meeting soul may pierce
In notes, with many a winding bout
Of *linked* sweetness long drawn out.

Id.

The thread and train of consequences in intellective ratiocination is often long, and chained together by divers *links*, which cannot be done in imaginative ratiocination, by some attributed to brutes.

Judge Hale.

Truths hang together in a chain of mutual dependence; you cannot draw one *link* without attracting others.

Glauville.

So gracious hath God been to us, as to *link* together our duty and our interest, and to make those very things the instances of our obedience, which are the natural means and causes of our happiness.

Tillotson.

Fire, flood, and earth, and air, by this were bound,
And love, the common *link*, the new creation crowned.

Dryden's Knight's Tale.

By which chain of ideas thus visibly *linked* together in train, i. e. each intermediate idea agreeing on each side with those two it is immediately placed between, the ideas of men and self-determination appear to be connected.

Locke.

Make a *link* of horse hair very strong, and fasten it to the end of the stick that springs.

Mortimer.

Though I have here only chosen this single *link* of martyrs, I might find out others among those names which are still extant, that delivered down this account of our Saviour in a successive tradition.

Addison on the Christian Religion.

While she does her upward flight sustain,
Touching each *link* of the continued chain,
At length she is obliged and forced to see
A first, a source, a life, a deity.

Prior.

So from the first eternal order ran,
And creature *linked* to creature, man to man.

Pope.

The three principal *links* in this chain are sympathy, imitation, and ambition.

Burke on the Sublime.

Ask not the boy, who, when the breeze of morn
First shakes the glittering drops from every thorn,
Unfolds his flock, then under bank or bush
Sits *linking* cherry stones, or platting rush,
How fair is Freedom?

Cowper.

Steel were the knots, and steel the twisted thong,
Ring *linked* in ring, indissolubly strong;
On viewless hooks along the fretted roof
Hehung, unseen, the inextricable woof.

Darwin.

'Tis something, in the dearth of fame,

Though *linked* among a fettered race,

To feel at least a patriot's shame,

Even as I sing, suffuse my face.

Byron.

LINK, *n. s.* } Goth. *lugin*; Gr. *λυχνος*. A
LINKBOY, } torch of pitch: link boy or
LINKMAN, } man, the bearer of this useful
invention.

O, thou art an everlasting bonfire light; thou
hast saved me a thousand marks in *links* and torches,
walking with thee in the night betwixt tavern and
tavern.

Shakspeare. Henry IV.

There was no *link* to colour Peter's hat.

Shakspeare.

Whereas history should be the torch of truth, he
makes her in divers places a fuliginous *link* of lies.

Howel.

One that bore a *link*

On a sudden clapped his flaming cudgel,
Like linstock to the horse's touch-hole.

Hudibras.

What a ridiculous thing it was, that the continued shadow of the earth should be broken by sudden miraculous disclusions of light, to prevent the officiousness of the *linkboy*!

Morr.

Round as a globe, and liquored every chink,

Goodly and great he sails behind his *link*.

Dryden.

Though thou art tempted by the *linkman's* call,
Yet trust him not along the lonely wall.

Gay.

In the black form of cinder-wench she came,

O may no *linkboy* interrupt their love!

Id.

LINLITHGOW (from Lin, Gael. i. e. a lake, lith, a twig, and gow, a dog), a royal borough in Scotland, capital of the county. The name is said to allude to a black bitch, which, according to tradition, was found tied to a tree in a small island, on the east side of the lake, near which the town stands. This etymology seems confirmed from the figure of the black bitch making part of the town's armorial bearing, on its public seal. Others, however, derive the name from lin, a lake, lith, snug or close, and gow, a vale, which seems confirmed from its situation. It was a royal borough in the time of David I. On the accession of the house of Stuart it became a royal residence. James IV. was much attached to it, and built the east part of the palace, which has been peculiarly magnificent. Several queens of Scotland held it as their jointure. It is built of polished stone, and covers an acre of ground forming a square with towers at the corners, and standing on a gentle eminence, with the lake behind it on the west. It was greatly ornamented by James V. and VI. Within it is a handsome square; one side of which was built by James VI., and kept in repair till 1746, when it was accidentally damaged by the king's troops.

making fires on the hearths, by which the joists were burnt. A stone ornamental fountain in the middle of the court was destroyed at the same time. The other sides of the square are more ancient. Narrow galleries run quite round the old part, to preserve communications with the rooms; in one of which the unfortunate Mary queen of Scots was born. The town consists of one open street of stone houses, three-quarters of a mile long, with lanes on each side, and gardens on the north and on the south. On the north side of the High Street, on an eminence east of the palace, stands St. Michael's church. In the market place is another fountain of two stories with eight spouts, and surmounted like the former with an imperial crown. The gallery, whence the regent Murray was shot, is still to be seen. The house of Carmelites, founded in 1290, was destroyed by the reformers in 1539. This borough is governed by a provost, four bailies, dean of guild, treasurer, twelve merchant-councillors, and eight deacons of incorporations. The market is on Friday, and there are six fairs. A considerable trade is carried on in leather, flax, wool, stockings, linen, porter, ale, &c. Linlithgow is two miles south of Borrowstownness, its port, and sixteen west of Edinburgh.

LINLITHGOW. See LOTHIAN WEST.

LINNE' (Sir Charles), the celebrated reformer of botany and natural history, was born on May 24th, 1707, in a village called Roesult in Smaaland, where his father, Nicholas Linné was then vicar. The name assumed by this great man, even in his Latin works, is neither *Lindelius*, nor *Linnæus*, but *Linné*, which seems to be the real Swedish name of the family. In his Latin works, printed in Sweden, he styles himself *Carolus à Linné*. How he came to be styled *Linnaeus* by foreigners is therefore not easily accounted for.

His taste for botany seems to have been imbibed from his father; who cultivated a garden plentifully stored with plants, by way of amusement. Young Linné soon became acquainted with these, as well as with the indigenous ones of his neighbourhood. In 1717 he was sent to school at Wexjö; where, as his opportunities were enlarged, his progress in all his favorite pursuits was proportionably extended; and even at this early period he began to study the natural history of insects. Professor Stobæus, under whom he received the first part of his academical education at Lund, in Scania, favored his inclination to natural history. He removed in 1728 to Upsal, where he contracted a close friendship with Artedi, a native of Angermania, who had been four years a student in that university, and had a strong bent to natural history, particularly ichthyology. Soon after his arrival at Upsal, he obtained the favor of several gentlemen of established character in literature. He was particularly encouraged in the pursuit of his studies by Dr. Olaus Celsius, then professor of divinity, and the restorer of natural history, in Sweden; who, being struck with the accuracy of Linné in describing the plants of the garden at Upsal, admitted him to his house, his table, and his library. Under his patronage Linné made such a rapid progress, that in two years he was thought qualified to give lectures in the botanic chair, in the

room of professor Rudbeck. In 1731 the Royal Academy of Sciences at Upsal, with a view to improve the natural history of Sweden, at the instance of professors Celsius and Rudbeck, deputed Linné to make the tour of Lapland, and explore the natural history of that arctic region. He left Upsal the 13th of May, by the route of Gevalia, the capital of Gesticria, forty-five miles from Upsal, and travelled through Helsingland into Medelpadia. Thence he went through Angermanland to Hernösand, a sea-port on the Bothnic Gulf; where he visited the remarkable caverns on the summit of mount Skula, though at the hazard of his life. Arriving at Uma, in West Bothnia, he quitted the public road, and took his course through the woods westward, to the most southern parts of Lapland. Though a stranger to the language and manners of the people, and without any associate, he trusted to the hospitality of the inhabitants, and mentions, with peculiar satisfaction, the innocence and simplicity of their lives. He now arrived at the mountains of Norway, and, after encountering great hardships, returned to West Bothnia; visited Pitha and Lula, on the gulf of that name; from which last place he took a western route, proceeding up the river Lula, and visited the ruins of the temple of Jockmock in Lappmark: thence he traversed the Lapland desert, destitute of all villages, cultivation, roads, or any conveniences, and inhabited only by a few straggling people, originally descended from the Finlanders. Hence he crossed the Lapland Alps into Finmark, and traversed the shores of the North Sea as far as Sallero. These journeys were made on foot, attended by two Laplanders, as his interpreter and guide. In descending a river, he narrowly escaped perishing by the oversetting of the boat, and lost many of the natural productions he had collected. He now spent the greater part of the summer in examining this arctic region, and those mountains on which, four years afterwards, the French philosophers secured immortal fame to Sir Isaac Newton. At length, after having suffered incredible fatigues and hardships, he returned in September to Tornö. Having next resolved to visit and examine the country on the east side of the gulf, his first stage was to Ula in East Bothnia; thence to Old and New Carleby, eighty-four miles south of Ula. He continued his route through Wasa, Christianstadt, and Biorneburgh, to Abo, a small university in Finland. As winter was at this time setting in, he crossed the gulf by the island of Åland, and arrived at Upsal in November, after having performed, mostly on foot, a journey of 10° of lat. in extent, exclusively of numberless deviations. In 1733 he visited and examined the mines in Sweden. The outlines of his system of mineralogy appeared in the early editions of the *Systema Naturæ*; but he did not exemplify the whole until 1768. In 1734 he was sent by baron Reuterholm, governor of Dalecarlia, with several other naturalists in that province, to investigate the productions of that part of the Swedish dominions; and published the result under the title of *Pan Suecus*, in the second volume of the *Amœnitates Academicæ*. After this expedition, Linné resided some time at Fahlun, the chief

own in Dalecarlia; where he taught mineralogy, and practised physic. He contracted at this time in intimacy with a daughter of Dr. More, the physician of the place, whom he married about five years afterwards. In 1735 he travelled over many parts of Sweden, Denmark, and Germany, and fixed in Holland, where he chiefly resided until his return to Stockholm, about 1739. In 1735 he took his degree of M. D., and published the first sketch of his *Systema Naturæ*, in the form of tables, in twelve pages folio. By this it appears that he had, before he was twenty-four years old, laid the basis of that structure which ye afterwards erected to the increase of his own fame, as well as of natural science. In 1736 he came to England, and visited Dr. Dillenius, of Oxford, whom he justly considered as one of the first botanists in Europe. He mentions the privilege he gave him of inspecting his own and the Sherardian collection of plants. He also became acquainted with Dr. Martyn, Mr. Rand, Mr. Miller, and Dr. Isaac Lawson, and Mr. Peter Collinson.

Early in 1738 Linné had a long and dangerous fit of sickness; and upon his recovery went to Paris, where he was entertained by the Jussieus, then the first botanists in France. The opportunity this gave him of inspecting their Herbaria, as well as those of Surian and Tournefort, afforded him great satisfaction. He did not fail to avail himself of every advantage which access to the several museums of that country afforded him in every branch of natural history; and the number and importance of his publications, during his absence from Sweden, demonstrate the fund of knowledge which he had accumulated before, as well as his extraordinary application. These were, *Systema Naturæ*, *Fundamenta Botanica*, *Bibliotheca Botanica*, and *Genera Plantarum*; the last of which is justly considered as the most valuable of all his works. Before the publication of the first edition, the author had examined the characters of 8000 flowers. The last book he published, during his stay in Holland, was the *Classes Plantarum*, which is a copious illustration of the second part of the *Fundamenta*. About the end of 1738, or beginning of 1739, he settled as a physician at Stockholm. By the interest of count Tessin, his patron, he obtained the rank of physician to the fleet, and a salary for giving lectures on botany. The establishment of the Royal Academy of Sciences at Stockholm, was highly favorable to the advancement of his character and fame; he was constituted the first president. By the rules of the academy, this officer held his place but three months. At the expiration of that term, Linné made his *Oratio de memorabilibus in Insectis*, October 3d, 1739; in which he endeavours to excite an attention to entomology. In 1741, upon the resignation of Dr. Roberg, he was constituted professor of physic and physician to the king of Sweden. During the interval of his removal from Stockholm to Upsal, in consequence of this appointment, he was deputed by the states to make a tour to the islands of Oeland and Gothland in the Baltic, attended by six pupils. On his return he pronounced before the university his *Oratio de Pægrinationum intra*

Patriam necessitate, October 17th, 1741. Linné was now fixed in the situation best adapted to his character, taste, and abilities; but, when he was appointed professor, the garden did not contain above fifty exotic plants. His correspondence with the first botanists in Europe soon supplied him with great variety. He received Indian plants from Jussieu of Paris, and Van Royen of Leyden; European plants from Haller and Ludwig; American plants from the late Mr. Collinson, Mr. Catesby, and others; and many annuals from Dillenius. How much the garden owed to his diligence and care, in a few years, may be seen by the catalogue entitled *Hortus Upsaliensis, exhibens Plantas exoticas horto Upsaliensis Academiæ a sese (Linnæo) illatas ab anno 1742, in annum 1748; additis differentiis, synonymis, habitationibus, hospitiiis, rariorumque descriptionibus, in gratiam studiosæ juventutis*; Holm. 1748, 8vo. pp. 306, tab. 3. By this it appears, that he had introduced 1100 species, exclusively of all the Swedish plants and of varieties; which last, in ordinary gardens, often amount to one-third of the whole. The fame which Linné had now acquired by his *Systema Naturæ*, of which a sixth edition, much enlarged, had been published at Stockholm in 1748, in 8vo., with plates and eight tables explanatory of the classes and orders, had brought him a conflux of every thing rare and valuable in every branch of nature and from all parts of the globe. The king and queen of Sweden had their separate collections of rarities; the former at Ulricdsdal; the latter, very rich in exotic insects and shells, procured at great expense, at the palace of Drottningholm; both of which our author was employed in arranging and describing. The museum of the royal academy of Upsal had also been augmented by a considerable donation from the king, whilst hereditary prince, in 1746; by another from count Gyllenborg in 1745; by a third from M. Grill, an opulent citizen of Stockholm.

Linné from this time sustained a more elevated rank. His reputation had procured him honours from almost all the royal societies in Europe; and Adolphus Frederick created him in 1753 a knight of the polar star, and in 1757 a noble of Sweden. His successor Gustavus III. doubled his pension in 1776, and settled a liberal donation of landed property on his family. In reply to an invitation to Madrid from the king of Spain, with the offer of a pension for life of 2000 pistoles, letters of nobility, and the free exercise of his own religion, he returned for answer, 'that if he had any merits they were due to his own country.' Soon after this Linné obtained the *præmium centum aureorum*, proposed by the imperial academy of sciences at Petersburg, for the best paper written to establish or disprove by new arguments the doctrine of the sexes of plants.

Linné, on the whole, enjoyed a good constitution, but was sometimes severely afflicted with a hemicrania, as well as with the gout. In the close of 1776 he was seized with an apoplexy, which left him paralytic; and at the beginning of 1777 suffered another stroke, which much impaired his powers. But the disease supposed to

have been the immediate cause of his death, was an ulceration of the urinary bladder; of which, after a tedious indisposition, he died, January 11th, 1778, aged seventy-one. His other principal works are, *Iter Oelandicum et Gotlandicum*: *Iter Scanicum*: *Flora Suecica*: *Materia Medica*: *Philosophia Botanica*: *Genera Morborum*: different papers in the *Acta Upsaliensia*, and the *Amœnitates Academicæ*. The last of his treatises was the *Mantissa Altera*, published in 1771; but before his death he had finished the greatest part of the *Mantissa Tertia*, afterwards completed and published by his son. On his death a general mourning took place at Upsal, and his funeral was attended by the whole university, and the pall supported by sixteen doctors of physic, all of whom had been his pupils. The king lamented his death in his speech to the states, and ordered a medal to be struck in his memory. Nor was Linné honored only in his own country. The professor of botany at Edinburgh, Dr. Hope, pronounced an eulogium in honor of him before his students, at the opening of his lectures in spring 1778, and erected a monument to his memory in the botanic garden there. He possessed a lively imagination, a strong judgment, the most retentive memory, unremitting industry, and the greatest perseverance in all his pursuits. Perhaps there is no circumstance of his life, however, which shows him in a more dignified light than his conduct towards his opponents. Disavowing controversy he replied to no one of them. He had a happy command of the Latin language; and has altogether, perhaps, advanced the literary honor of his country more than any other of her sons. Natural history arose in Sweden, under his culture, to a state of perfection unknown elsewhere; and was thence disseminated through all Europe.

L'INNET, *n. s.* Fr. *linot*; Lat. *linaria*. A small singing bird.

The swallows make use of celandine, the *linnet* of euphrasia, for the repairing of their sight.

More's Antidote.

Is it for thee the *linnet* pours his throat? Pope.

Congregated thrushes, *linnets*, sit

On the dead tree, a dull despondent flock.

Thomson.

Far dearer to me are yon humble broom bowers,

Where the blue-bell and gowan lurk lowly unseen;

For there, lightly tripping among the wild flowers,

A listening the *linnet*, aft wanders nay Jean.

Burns.

LINNET, in ornithology. See **FRINGILLA**. These birds build in hedges, as well as in furze bushes on heaths, but with very different materials. In hedges they use the slender filaments of the roots of trees, and the down of feathers and thistles; but on heaths they use moss, principally for the outer part, finishing it within with such things as the place affords. They have young ones three or four times a year, especially if they are taken away before they are able to leave the nests. When *linnets* are to be taught to whistle tunes, or to imitate the notes of any other bird, they must be taken from the old one when they are not above four days old; for at this time they have no idea of the note of the

old ones, and will be readily taught to modulate their voice like any thing that is most familiar to their ears, and within the compass of their throats. More care is required in feeding them when taken thus young, than when they are left in the nest till nearly fledged; but they will be reared very well upon a food half bread and half rape-seed boiled and bruised: this must be given them several times a day. It must be made fresh every day, and given sufficiently moist, but not in the extreme. If it be in the least sour, it gripes and kills them; and if too stiff it is as mischievous by binding them up. They must be hung up as soon as taken from the nest under the bird whose note they are intended to learn; or, if they are taught to whistle tunes, it must be done by giving them lessons at the time of feeding; for they will profit more while young in a few days than in a long time afterwards, and will take in the whole method of their notes before they are able to crack hard seeds. Some have attempted to teach them to speak, and they often arrive at some perfection in that art!

LINSEED, *n. s.* Lat. *semen lini*. The seed of flax, which is much used in medicine.

The joints may be closed with a cement of lime, linseed oil, and cotton. *Mortimer's Husbandry.*

Linseed cakes, in agriculture, is the name of such cakes as remain after the expression of the oil from flax seed. They are at present much used in the fattening of cattle, sheep, and other sorts of live stock, and of course of great value and importance to the farmer. *Dr. A. Rees.*

LINSEED, or more properly **LINT-SEED**, is the seed of the plant *linum*. Lint-seed steeped and bruised in water gives it very soon a thick mucilaginous nature, and communicates much of its emollient virtue to it. See **LINUM**.

LINSEYWOOLSEY, *adj.* From linen and wool. Linen and wool mixed: hence of different and unsuitable parts; vile; mean.

A lawless *linseywoolsey* brother,

Half of one order, half another. *Hudibras.*

Peeled, patched, and pyebald, *linseywoolsey* brothers,

Grave mummings! sleeveless some, and shirtless others. *Pope.*

LINSTOCK, *n. s.* Teut. *lunte* or *lente*, (a match cord), and stock. A staff of wood with a match at the end of it, used by gunners.

The nimble gunner

With *lynstock* now the devilish cannon touches,
And down goes all before him. *Shakspeare.*

The distance judged for shot of every size,

The *linstocks* touch, the ponderous ball expires.

Dryden.

A **LINSTOCK**, or **LINTSTOCK**, in military affairs, is about three feet long, and has a sharp point on one end, and a fork or crotch on the other; the latter serves to contain a lighted match, and by the former the linstock is occasionally stuck in the ground, or in the deck of a ship during an engagement. It is used in small vessels, where one is fixed between every two guns, by which the match is always kept dry, and ready for firing.

LINT. Sax. *linet*; Lat. *linteum*. A flaxen substance; linen scraped.

I dressed them up with unguentum basilici cum vitello ovi, upon pledgets of lint.

Wiseman's Surgery.

Lint made up in an oval, or orbicular form, is called a pledget; if in a cylindrical form, or in the shape of a date olive-stone, it is called a dossil.

Dr. A. Rees.

LINT, in surgery, is made into various forms, which acquire different names according to the difference of their figures. Made up in an oval or orbicular form, it is called a pledget; in the shape of a date or olive-stone, as we have seen, a dossil. These different forms are required for many purposes; as 1. To stop blood in fresh wounds, by filling them up with dry lint before the application of a bandage: though, if scraped lint be not at hand, a piece of fine linen may be torn into small rags, and applied in the same manner. In very large hæmorrhages the lint or rags should be first dipped in some styptic liquor, as alcohol, or oil of turpentine; or sprinkled with some styptic powder. 2. To agglutinate or heal wounds; to which end lint is very serviceable, if spread with some digestive ointment, balsam, or vulnerary liquor. 3. In drying up wounds and ulcers, and forwarding the formation of a cicatrix. 4. In keeping the lips of wounds at a proper distance, that they may not hastily unite before the bottom is well digested and healed. 5. They are highly necessary to preserve wounds from the injuries of the air. Surgeons of former ages formed compresses of sponge, wool, feathers, or cotton; linen being scarce: but lint is far preferable to all these, and is at present universally used.

LINTEL, *n. s.* *Fr. linteau.* The head piece of a door frame.

Take a bunch of hyssop, and dip it in the blood that is in the bason, and strike the lintel and the two side-posts.

Exod.

Smite the lintel that the posts may shake.

Amos ix. 1.

The Israelites' doors, whose lintels were besprinkled with blood, were passed over by the destroying angel.

Bp. Hall.

When you lay any timber or brick work, as lintels over windows, lay them in loam, which is a great preserver of timber.

Moxon.

Silver the lintels deep projecting o'er,

And gold the ringlets that command the door.

Pope's Odyssey.

LINTERNUM, or LITERNUM, in ancient geography, a city of Campania, situated at the mouth of the Clanius, or Liturnus, between Cumæ and Vulturum. It received a Roman colony at the same time with Puteoli and Vulturum; was improved and enlarged by Augustus; afterwards forfeited its right of colonyship, and became a prefecture. Hither Scipio Africanus the elder retired from the envy of his ungrateful countrymen; and here he died. No vestige of the place now remains.

LINTZ, the capital of Upper Austria, is situated at the confluence of the Danube and Traun. It is a bishop's see; has a hall in which the states meet; a wooden bridge over the Danube; and several manufactories. The houses are in general respectable, but roofed with shingle. The church of St. Ignatius is worth notice, and the remaining castle, for in 1800 one was de-

stroyed by fire. Here a lyceum, two public schools, a public library, an institution for the deaf and dumb, and a large theatre. The manufactures are of linen (in which 30,000 hands are said to be employed), looking-glasses, gunpowder, and bottles. The town has two good annual fairs, at Easter and the Assumption: the environs are very fertile and picturesque. It was burnt in 1542. It was taken by the French in 1741, but retaken by the Austrians in 1742. Lintz is forty-two miles E. S. E. of Passau, and ninety-four west of Vienne.

LINUM, flax; a genus of the pentagynia order, and pentandria class of plants: *cal.* pentaphyllous; petals five: *caps.* quinquevalved and decemlocular: *seeds*, solitary. There are thirty species.

1. *L. catharticum*, the purging flax, has leaves opposite and lanceolate; the stem bifurcated, and the corollæ acute. This plant is not above four or five inches high, and is found wild upon chalky hills, and in dry pleasure grounds. Its virtue is expressed in its title; an infusion in water or whey of a handful of the fresh leaves, or a drachm of them in substance when dried, may be used as a cathartic without inconvenience.

2. *L. perenne*, the perennial Siberian flax, has a fibrous perennial root, sending up several upright, strong, annual stalks, branching four or five feet high; garnished with small, narrow, spear-shaped, alternate leaves, of a dark-green color; and terminated by umbellate clusters of large blue flowers in June, succeeded by seeds in autumn. This species is raised from seed in a bed or border of common garden earth, in shallow drills six inches asunder; when the plants are two or three inches high, thin them to the same distance; and in autumn plant them out where they are wanted.

3. *L. usitatissimum*, the common annual flax, has a taper fibrous root; upright, slender, unbranched stalks, two feet and a half high; garnished with narrow, spear-shaped, alternate, gray-colored leaves; and the stalks divided into foot-stalks at top, terminated by small blue crenated flowers in June and July; succeeded by large round capsules of ten cells, containing each one seed. This species may justly be looked upon as one of the most valuable of the whole vegetable kingdom: as from the bark of its stalks is manufactured the lint or flax for making all sorts of linen cloth; from the rags of the linen is made paper; and from the seeds is expressed the linseed oil, so useful in painting and other trades. The seeds are an excellent emollient and anodyne; they are used externally in cataplasms, to assuage the pain of inflamed tumors; internally a slight infusion of them by way of tea, in coughs, is an excellent pectoral, and of great service in pleurisies, nephritic complaints, and suppressions of urine. For the cultivation, dressing, &c., of this species, see FLAX.

LINUS, in classical history, a native of Colchis, contemporary with Orpheus, and one of the most ancient poets and musicians of Greece. According to archbishop Usher, he flourished about 1280 B. C., and he is mentioned by

Eusebius among the poets who wrote before the time of Moses. Diodorus Siculus tells us, from Dionysius of Mitylene the historian, who was contemporary with Cicero, that Linus was the first among the Greeks who invented verses and music, as Cadmus first taught them letters. He likewise attributes to him an account of the exploits of the first Bacchus, and a treatise upon Greek mythology, written in Pelasgian characters, which were also those used by Orpheus, and by Pranopidas the preceptor of Homer. Diodorus says that he added the string lichanos to the Mercurian lyre, and ascribes to him the invention of rhyme and melody; which Suidas, who regards him as the most ancient of lyric poets, confirms. Mr. Marpurge tells us, that Linus invented cat-gut strings for the use of the lyre which, before his time was only strung with thongs of leather, or with different threads of flax strung together. He had several disciples of great fame; among whom were Hercules, Thamyris, and, some add, Orpheus. Hercules, says Diodorus, in learning from Linus to play upon the lyre, being extremely dull and obstinate, provoked his master to strike him; which so enraged him that instantly seizing the lyre of the musician, he beat out his brains with his own instrument.

L'ON, *n. s.* } Fr. *lion*; Span. *leon*; Ital.
L'ONESS. } *leone, lionc*; Lat. *leo*. A species of FELIS. See below.

So a *lion* of the lynage of iuda, the roote of dauid, hath ouercomen to opene the book, and to undo the sevene seel of it. *Wiclif. Apoc. 5.*

The *lion* did tear in pieces enough for his whelps, and strangled for his *lionesses*, and filled his holes with prey, and his dens with ravin. *Nahum ii. 12.*

Be *lion* mettled; proud, and take no care
Who chafes, who frets, or where conspirers are;
Macbeth shall never vanquished be.

Shakspeare. Macbeth.

Under which bush's shade, a *lioness*
Lay couching head on ground, with catlike watch,
When that the sleeping man should stir.

Shakspeare.

King Richard's surname was Coeur-de-Lion, for his *lion-like* courage. *Camden's Remains.*

The sphinx, a famous monster in Egypt, had the face of a virgin, and the body of a *lion*.

Peacham on Drawing.

The furious *lioness*,
Forgetting young ones, through the fields doth roar.

May.

It hath ever been the fashion of God, to exercise his champions with some initiatory encounters: both Sampson and David must first fight with *lions*, then with Philistines; and he, whose type they bore, meets with that roaring *lion* of the wilderness, in the very threshold of his public charge. *Bp. Hall.*

The *lion* for the honours of his skin,
The squeezing crab, and stinging scorpion shine
For aiding heaven, when giants dared to brave
The threatened stars. *Creech's Manilius.*

They rejoice

Each with their kind, *lion* with *lioness*;
So fitly them in pairs thou hast combined. *Milton.*

The greedy *lioness* the wolf pursues,

The wolf the kid, the wanton kid the browse.

Dryden.

See *lion-hearted* Richard,
Proudly valiant, like a torrent swelled
With wintry tempests, that disdains all mounds.

Breaking away impetuous, and involves
Within its sweep trees, houses, men, he pressed,
Amidst the thickest battle. *Phillips.*

If we may believe Pliny, *lions* do, in a very severe manner, punish the adulteries of the *lioness*.

Ayliffe.

LION, in zoology. See FELIS. The lion is frequently hunted for the sake of the flesh, which, though possessing a strong and disagreeable flavor, is eaten by the negroes, and also for the skin. In the day time, and on the open plain, from ten to sixteen dogs will easily overcome one of the largest lions. Nor is there any necessity that the dogs with which the lion is hunted should be trained up for the sport: the common farmhouse dogs will serve. As the lion is less swift than the dogs, the latter easily approach him, when, with sullen magnanimity, the lion turns round, and waits for the attack, shaking his mane, and roaring with a short and sharp tone. The hounds then surround him, and, all rushing upon him at once, are able, by their united efforts, to subdue, or tear him in pieces; he has seldom time to give more than two or three slight strokes with his paws, each of which, however, is attended with the death of one of his assailants.

The lion is sometimes hunted by parties of horsemen, in which case the horses should be trained to the purpose, or at least accustomed to the pursuit of beasts of prey, and the perils attendant on their chase; and it is only on the plains that the hunters ever venture to go out on horseback in this chase. If the lion remains in the jungle, or on a rising ground, they endeavour to tease him with the dogs till he comes into the plain. If the lion sees the hunters at a great distance, he flies from them with all possible speed; but, if they chance to discover him at a small distance only from them, he retires with sullen dignity, and at a slow pace, as though he were above showing any symptom of apprehension. If pursued, he soon slackens his pace, and at length only slides slowly off, step by step, at the same time watching his pursuers obliquely, till he finally makes a full pause, and, turning round upon them, shakes his mane, roars, and appears ready to seize upon them, and tear them in pieces. The foremost huntsman, or he who has the best mark at that part of the lion's body nearest his heart or lungs, is now the first to jump off his horse, and, securing the bridle by putting it round his arm, discharges his piece; then, in an instant recovering his seat, rides obliquely athwart his companions; and, giving his horse the reins, depends entirely on the speed and fear of the latter to convey him beyond the reach of the lion, should he have only wounded him. A fair opportunity now presents itself for some one of the other hunters to jump off his horse immediately, as he may then discharge his piece with effect, and save his companion. If this shot should miss likewise, a third sportsman rides after the lion, which is in pursuit of the first or second, and, springing off his horse, fires his piece as soon as he arrives within a proper distance. In the event of the lion turning again and attacking this pursuer, the other hunters return to his rescue with their pieces ready

charged, having loaded them while flying. No instance, it is said, has ever been known of any misfortune happening the hunters in chasing the lion on horseback. The remote parts of Africa are most exposed to the ravages of wild beasts, and the colonists in those districts, from the habit of hunting them, become excellent marksmen.

Mr. Wombwell's late attempt to bring a certain number of trained dogs upon one or two lions, we consider, on the whole, not worthy of detail in a work of science. It terminated only in the partial worrying of the lions selected, and established no new facts with regard to their habits, or natural history.

The LION MOUNTAIN of the Cape of Good Hope, Africa, rises immediately behind Cape Town. The summit is a mass of stone, much resembling from some points of view the dome of St. Paul's. It is 2160 feet in height, and is surmounted by a single post. It is properly part of the Table Mountain.

LIONCELLES, in heraldry, a term used for several lions borne in the same coat of arms.

LIOTARD, an eminent painter, born at Geneva, in 1702, and by his father designed for a merchant; but his genius inclined him to painting. He went to Paris in 1725, and in 1738 accompanied the marquis de Puisieux to Rome, where he was taken notice of by lords Sandwich and Duncannon, who engaged him to go with them to Constantinople. There he became acquainted with lord Edgecombe, and Sir Everard Fawkener, who brought him to England, where he staid two years. In his journey to the Levant he adopted the eastern habit, and wore it in Britain with a very long beard, whence he was called the Turk. After his return to the continent he married a young wife, and sacrificed his beard to Hymen. He came again to England in 1772, and brought a collection of pictures of different masters, which he sold by auction, and some pieces of glass painted by himself, with surprising effect of light and shade, but mere curiosities, as it was necessary to darken the room before they could be seen to advantage. He engraved some Turkish portraits, one of the empress queen and the eldest arch-duchess in Turkish habits, and the heads of the emperor and empress. He painted admirably well in miniature, and finely in enamel, though he seldom practised it. But he is best known by his works in crayons. His likenesses were as exact as possible, and too like to please those who sat to him: thus he had great business the first year, and very little the second. Devoid of imagination, and one would think of memory, he could render nothing but what he saw before his eyes. Freckles, marks of the small-pox, every thing found its place; not so much from fidelity, as because he could not conceive the absence of any thing that appeared to him. Truth prevailed in all his works, grace in few or none.

LIP, *n.s. & v. a.* } Sax. *lippe*; Fr. *lippe*;
 LIP-LABOR, *n. s.* } Teut. Belg. and Swed. *lip*;
 LIP-WISDOM. } Lat. *labia*. The edge or
 outer part of the mouth; hence the edges of a wound or any aperture: to lip is to hiss: lip-labor is well defined below by bishop Taylor: lip-wisdom, verbiage.

By hym offre we a sacrifice of heriynge evermore to god, that is to seie, the fruyt of *lippes* knowlechuge to his name. *Wiclif. Ebreus xiii.*

No falsehood shall defile my *lips* with lies

Or with a veil of truth disguise. *Sandys on Job.*

Then in the midst a tearing groan did break

The name of Antony: it was divided

Between her heart and *lips*.

Shakspeare.

Those happiest smiles

That played on her ripe *lip*, seemed not to know

What guests were in her eyes.

Id.

O! 'tis the fiend's arch mock,

To *lip* a wanton and suppose her chaste.

Id.

A letter for me! It gives me an estate of seven years health; in which time I will make a *lip* at the physician.

Id.

And if some have fetched new noses, and *lips*, and ears from Italy, by the help of Tagliacotius and his scholars, never any brought a new tongue from thence.

Hp. Hall.

Methinks to kiss ladies' hands after their *lips*, as some do, is like little boys, who, after they eat the apple, fall to the paring, out of love they have to the apple.

Selden.

Fasting, when prayer is not directed to its own purposes, is but *lip-labour*.

Taylor's Rule of Living.

I find that all is but *lip-wisdom*, which wants experience; I now, woe is me, do try what love can do.

Sidney.

In many places is a ridge of mountains some distance from the sea, and a plain from their roots to the shore; which plain was formerly covered by the sea, which bounded against those hills as its first ramparts, or as the ledges or *lips* of its vessel.

Burnet.

In wounds, the *lips* sink and are flaccid; a gleet followeth, and the flesh within withers.

Wiseman.

Her *lips* blush deeper sweets.

Thomson's Spring.

Oh that those *lips* had language! life has passed

With me but roughly since I heard thee last.

Those *lips* are thine—thy own sweet smiles I see,

The same that oft in childhood solaced me.

Cowper.

Or touch the shrill reed, as they trip,

With finger light and ruby *lip*.

Darwin.

LIPARA, in ancient geography, the principal of the islands called *Æoliz*, situated between Sicily and Italy, with a cognominal town, so powerful as to have a fleet, and other islands in subjection to it. Diodorus Siculus says, it was famous for excellent harbours and medicinal waters; and that it suddenly emerged from the sea about the time of Hannibal's death. The name is Punic, according to Bochart; and given it, because, being a volcano, it shone in the night. It is now called Lipari, and gives name to nine others in its neighbourhood.

LIPARI ISLES.—The Lipari islands, twelve in number, are situated at the south-east extremity of the Tuscan Sea, off the north coast of Sicily. They received from the ancients the names of *Æolian* and *Vulcanian* islands, it being supposed that *Æolus* kept the winds imprisoned in their caverns, and that they contained the forges of Vulcan. The first volcanic eruption in the Lipari islands, recorded in history, is that which Callius mentions in his History of the Wars in Sicily. Callius was contemporary with Agathocles. That eruption continued without interval for several days and nights; and threw out great stones, which fell above a mile distant. The sea boiled all round the island of Lipari, we are

told. During the consulship of Æmilius Lepidus and L. Aurelius Orestes, A. A. C. 126, these islands were affected with a dreadful earthquake. The burning of Ætna was the first cause of it. 'Around Lipari and the adjacent islands the air was all on fire.' Vegetables were burnt up, animals died, and fusible bodies, such as wax and resin, became liquid. If the inhabitants of Lipari, from whom Callius received these facts, and the writers who have handed them down to us, have not exaggerated matters, the sea boiled around the island; the earth became so hot as to burn the cables by which vessels were fixed to the shore, and consumed the planks, the oars, and even the small boats. Pliny speaks of a similar event, which happened thirty or forty years afterwards, in the time of the war of the allied states of Italy against Rome. One of the Æolian islands, says he, was on fire as well as the sea; and that prodigy continued to appear till the senate appeased by a deputation the wrath of the gods. From the time of that war, which happened A. A. C. 86, till A. D. 144, we have no account of an eruption of these volcanoes; and from that period again till 1444, we hear of no explosion from them for 1300 years. But at that time both Sicily and these isles were agitated by dreadful shocks of earthquakes; the Volcano isle poured forth streams of flame and smoke, which rose to an amazing height. After that it discharged enormous stones, which fell above six miles distant. In 1550 the ashes and stones discharged from its crater filled up the strait between Volcano and Volcanello. In 1739 there was a sixth eruption. The burstings of the volcanic fire were attended with a noise so dreadful, that it was heard as far as Melazzo in Sicily. In 1775 the whole island was shaken; subterraneous thunder was heard, and considerable streams of flame, with smoke, stones, and vitreous lava, issued from the crater. Lipari were covered over with ashes, and part of these was conveyed by the winds all the way into Sicily. In April 1780 there issued a new explosion from Volcano; the smoke was thick, the shocks constant, and the subterraneous noise very frequent. In 1783 the isles of Lipari were agitated anew by that fatal earthquake which ravaged Calabria, and part of Sicily, on the 5th of February. They are almost entirely composed of volcanised substances, and afford sulphur, nitre, alum, cinnabar, pumice stone, &c., in abundance. We enumerate the chief of them:—

1. The largest, most fertile, and best inhabited is Lipari (Lipara), five leagues in circuit; more than half of its surface is cultivated, the remainder being either covered with wood, or entirely barren. The vegetable productions are rye, nearly enough for its consumption, some cotton, and olives; but its chief riches are its vines, which give wines of various qualities, particularly a kind of malmsey. It also exports a considerable quantity of raisins. The prickly pear is indigenous in this island. It has many hot springs. On the south is a little town at the foot of a hill, rising abruptly from the sea; the houses, except those of the bishop and governor, are mean. It is defended by a castle on a naked

rock of lava, rising perpendicularly from the water. Close to its west side is a rock, called Pietro del Bagno.

2. Salini (Didime), is nearly as large as Lipari, and consists of two mountains united at the base. It has its name from the salt, which is formed by the sun in a lagoon, communicating with the sea. On the north side is a fine spring of water, gushing from a rock close to the shore. Off its south end are three rocks, called the Three Stones.

3. Volcano (Hieri and Therasia), is four leagues in circuit, and has the shape of a cone with the top broken off. It continually throws out volumes of smoke. It is uninhabited, and only occasionally visited by the other islanders, to cut brush-wood for fuel, which grows in the crater of an old volcano. Volcanello, anciently a distinct island, has been joined to Volcano by a narrow neck, formed by an eruption. On each side of the neck is a good road.

4. Stromboli (Strongyle) is one immense volcano, whose continual eruptions of flame have gained it the name of the Light-house of the Mediterranean. It is three leagues in circuit, and very barren, having only a few poor vineyards on the north side. There is no anchorage round it, and the small vessels that belong to or visit it are hauled on the beach. The number of inhabitants is about 1000, who live in scattered huts on the shore, and are principally employed in fishing for congers, which are abundant round the island. They chiefly depend on the rains for fresh water, the island having but two small springs. A mile from the north end is a great rock called the Stone of Stromboli, one-fourth of a mile in circuit, and sixty feet high.

5. Panaria (Ilycesia) is nearly three leagues in circuit, moderately elevated, and composed of volcanised granite, generally barren, but producing some olives. North of it are several lesser volcanic islands and rocks, viz. the Formiculas, or Ants, a group of rocks nearly level with the water, Dattolo, Lisca Nera (Black Lisca), Lisca Bianca (White Lisca), and Bottero, Tilanavi, and Panarelli.

6. Basiluzzo is only two miles in circuit, elevated but a few feet above the sea, and inhabited by half a dozen persons, who cultivate a small spot near its centre. It abounds with rabbits, and on the south-east coast is a little cove for boats.

7. Felicudi, or Filicuri (Phenicores), is composed of a group of hills, and has about 600 inhabitants in insulated dwellings. It has a natural cavern, called the Grotto of the Sea-Ox, in which is a kind of apartment 200 feet long, 120 broad, and sixty-five high. On the south and north-east sides of the island are coves for small vessels, according to the winds.

8. Alicudi, or Alicuri (Ericades), the westernmost island, has 400 inhabitants, who reside on the east and south-east sides, all the rest of the island being composed of volcanic barren precipices. This island, as well as Felicudi, produces some wine, barley, and rye, together estimated at 7000 Neapolitan crowns a year. Both islands are destitute of springs, and the inhabitants consequently depend on the rain-water preserved in their cisterns, which, in dry seasons,

is sometimes exhausted. Each island has four or six barks belonging to it; those of Alicudi are hauled on shore, there being no anchorage round it.

LIPOTH'YMOUS, *adj.* } Greek λειπω, to
LIPOTH'YMY, *n. s.* } faint or fail, and
θυμος, the animal spirit. Swooning; fainting;
fainting-fit.

If the patient be surprised with a *lipothymous* languor, and great oppression about the stomach and hypochonders, expect no relief from cordials.

Harvey on the Plague.

The senators falling into a *lipothymy*, or deep swooning, make up this pageantry of death with a representing of it unto life.

Taylor.

In *lipothymy* or swoonings, he used the frication of his finger with saffron and gold.

Browne.

LIPPE, or **LIPPE DETMOID**, a principality of Westphalia, adjoining Hanover and the Prussian states: the bailiwick of Lipperode is a detached part round the town of Lippstadt. The area of the principality has been computed at 434 square miles: the population at 73,000, who are mostly Calvinists. The Emma, Werra, Hamme, and Bever traverse its hilly surface, which is also diversified by large forests of oak and beech timber. Its chief manufactures are wool and cattle, which with its linen and yarn are largely exported by the Weser. It is divided into eleven bailiwicks.

LIPPERT (Philip Daniel), an ingenious artist in glass was born of poor parents, at Dresden, in 1703. Having studied drawing, and made himself acquainted with the Latin and Greek languages, he was appointed drawing-master to the pages of the elector, and his situation afforded him facilities for forming a collection of antiquities. He contrived a method of taking impressions in glass of ancient gems, a number of which he offered for sale, and of which he published a catalogue with the following title: *Genusmarum anaglyphicarum et diaglyphicarum, ex præcipuis Europæ Musæis selectarum ectypa* M. ex vitro obsidiano et massa quodam, studio P. D. Lippert fusa et afficta, Dresd. 4to. He published an account of a second collection in 1756, and of a third in 1763; besides other works. He died in 1785.

LIPPI (Lorenzo, or Lawrence), a painter of history and portraits, was born in 1606, and learned the principles of painting from Matthew Roselli. He had an exquisite genius for music and poetry, as well as for painting; and, in the latter, his proficiency was so great, that some of his compositions were taken for those of Roselli. He afterwards adopted the manner of Santi di Titi, who has more of simple nature and truth in his compositions than any other artist of that time. At Florence Lippi painted many designs for the chapels and convents, by which he enlarged his reputation; and produced at the court of Inspruck a great number of portraits of the nobility, which were deservedly admired. His works are held in the highest esteem for the graceful airs of their heads, the correctness of his outline, and the elegant disposition of the figures. He died in 1664.

LIPITUDE, *n. s.* Fr. *lippitude*; Lat. *lippitudo*. Blearedness of eyes.

Diseases that are infectious, are such as are in the spirits and not so much in the humours, and therefore pass easily from body to body: such are pestilences and *lippitudes*.

Bacon.

I flatter myself I shall soon get rid of this infirmity; nay, that I shall ere long be in the way of becoming a great man. For have I not head-aches, like Pope? vertigo, like Swift? grey hairs, like Homer? Do I not wear large shoes (for fear of corns), like Virgil? and sometimes complain of sore eyes (though not of *lippitude*), like Horace? *Beattie.*

LIPSIUS (Justus), a learned critic, born at Isch, a village near Brussels, in 1547. After having distinguished himself in literature, he became secretary to cardinal de Granveilan at Rome, where the best libraries were open to him; and he collated the MSS. of ancient authors. He lived twelve years at Leyden; during which he composed and published what he esteemed his best works; but settled at Louvain, where he taught polite literature with great reputation. He was remarkable for unsteadiness in religion, fluctuating often between the Protestants and Papists; but he became finally a bigotted Catholic. He died at Louvain in 1606; and his works are collected in 6 vols. folio.

LIPTAU, a mountainous and bleak palatinate of Hungary, traversed by the Carpathian Mountains: it has gold, silver, and iron mines, some precious stones; and is abundant in antimony. Its forests are also considerable; but there is much good pasturage, and the flocks of sheep are large. Population 64,000, about half of whom are Protestants. Szent-Miklos is the chief town.

LIQUABLE, *adj.*

LIQUATION, *n. s.*

LIQUATE, *v. n.*

LIQUEFACTION, *n. s.*

LIQUEFIABLE, *adj.*

LIQUEFFY, *v. a.*

LIQUESCENCY, *n. s.*

LIQUESCENT, *adj.*

LIQUID, *adj.* & *n. s.*

LIQUIDATE, *v. a.*

LIQUIDITY, *n. s.*

LIQUIDNESS, *n. s.*

LIQUOR, *n. s.* & *v. a.*

All these words seem to have their origin in the Lat. *liqueo* (*à lix*, water,) to melt or dissolve. Cognate words are, in Fr. *liquefaction*; *liquefier*; *liquide*, *liqueur*; Ital. *liquore*; and Port. *liquido*; Span. and Port. *licor*; Ital. *liquore*.

LIQUABLE and **LIQUEFFY** mean, that may be melted or made into liquid: **LIQUATION**, the act or capacity of being made so: to **LIQUATE** and to **LIQUEFY**, to melt, sink into liquidity: **LIQUEFACTION**, the act of melting or making liquid, or state of being melted: to **LIQUEFY** is, to dissolve; melt; make liquid: **LIQUESCENCY**, aptness or tendency to melt: **LIQUESCENT**, melting: **LIQUID**, fluid; not solid; dissolved; hence it means invalid, in law; soft; clear; gentle; flowing: a liquid and a liquor, as substantives, mean a fluid; a body in a liquid state; and the latter has a particular application to impregnated or strong fluids or drinks: to **LIQUOR** is to drink or moisten with liquid: to **LIQUIDATE** is synonymous with to **LIQUEFY**, but is more generally applied in the figurative sense of lessening or paying off debts: **LIQUIDITY** and **LIQUIDNESS** are subtilty; thinness; quality of being liquid. These words seem to have been multiplied in our language from the different cognate sources specified, until many of them have become redundant.

Thou shalt not delay to offer the first of thy ripe fruits, and of thy *liquors*. *Ezod. xxii. 29.*

Neither shall he drink any *liquor* of grapes.

Numbers vi. 3.

Heat dissolveth and melteth bodies that keep in their spirits, as in divers *liquefactions*; and so doth time in honey, which by age waxeth more liquid.

Bacon's Natural History.

There are three causes of fixation, the even spreading of the spirits and tangible parts, the closeness of the tangible parts, and the jejuneness or extreme comminution of spirits; the two first may be joined with a nature *liquefiable*, the last not.

Id.

That degree of heat which is in lime and ashes, being a smothering heat, is the most proper, for it doth neither *liquefy* nor rarefy; and that is true maturation. *Id.*

Cart wheels squeak not when they are *liquored*.

Bacon.

Her breast, the sug'red nest

Of her delicious soul, that there does lie,

Bathing in streams of *liquid* melody. *Crashaw.*

Return your superfluous *liquors* into tears of repentance, which only can quench that fire.

Ep. Hall.

Gently rolls the *liquid* glass.

Dr. Daniel.

Nor envied them the grape

Whose heads that turbulent *liquor* fills with fumes.

Milton.

The spirits, for their *liquidity*, are more incapable than the fluid medium, which is the conveyor of sounds, to persevere in the continued repetition of vocal airs.

Glanville.

The common opinion hath been, that chrystal is nothing but ice and snow concentered, and, by duration of time, congealed beyond *liquation*.

Broune's Vulgar Errors.

Oil of anniseeds, in a cool place, thickened into the consistence of white butter, which, with the least heat, resumed its former *liquidness*.

Boyle.

The many *liquid* consonants give a pleasing sound to the words, though they are all of one syllable.

Dryden's Æneid.

Be it thy choice, when summer heats annoy,

To sit beneath the leafy canopy,

Quaffing rich *liquids*.

Phillips.

The burning of the earth will be a true *liquefaction* or dissolution of it, as to the exterior region.

Burnet.

Sin taken into the soul is like a *liquor* poured into a vessel; so much of it as it fills, it also seasons.

South's Sermons.

The blood of St. Januarius *liquefied* at the approach of the saint's head.

Addison on Italy.

If a creditor should appeal to hinder the burial of his debtor's corpse, his appeal ought not to be received, since the business of burial requires a quick dispatch, though the debt be entirely *liquid*.

Ayliffe's Pavegon.

Why does she wake the correspondent moon,

And fill her willing lamp with *liquid* light.

Prior.

If the salts be not drawn forth before the clay is baked, they are apt to *liqueate*.

Woodward on Fossils.

Let Carolina smooth the tuneful lay,

Lull with Amalia's *liquid* name the nine,

And sweetly flow through all the royal line.

Pope's Horace.

When amatory poets sing their loves

In *liquid* lines melliflously bland,

And praise their rhymes as Venus yokes her doves,
They little think what mischief is in hand.

Byron.

In this state, being exposed in an earthen vessel to the naked fire, it readily becomes soft, but did not *liquefy* without considerable difficulty, rather frying as a piece of soap would do, and disengaging at the same time ammoniacal vapours. *Dr. A. Rees.*

LIQUEFACTION is an operation by which a solid body is reduced into a liquid; or the action of fire or heat on fat and other fusible bodies, which puts their parts into a mutual intestine motion. The liquefaction of wax, &c., is performed by a moderate heat; that of sal tartari, by the mere moisture of the air. All salts liquefy; sand, mixed with alkalies, becomes liquefied by a reverberatory fire, in the making of glass. In speaking of metals, instead of liquefaction, we ordinarily use the word fusion.

LIQUIDAMBART, sweet gum tree, in botany, a genus of the polyandria order, and monœcia class of plants. Male, *CAL.* common, triphyllous: *COR.* none, but numerous filaments. Female, *CAL.* collected into a spherical form, and tetraphyllous: *COR.* none, but seven styles; and many bivalved and monospermous CAPSULES collected into a sphere. There are only two species, both deciduous, viz.—

1. *L. peregrinum*, Canada liquidambar, or spleenwort-leaved gale, is a native of Canada and Pennsylvania. The young branches are slender, tough, and hardy. The leaves are oblong, of a deep green color, hairy underneath, and have indentures on their edges alternately very deep. The flowers come out from the sides of the branches, and they are succeeded by small roundish fruit, which seldom ripens in England.

2. *L. styraciflua*, the Virginia or maple-leaved liquidambar; a native of the rich moist parts of Virginia and Mexico. It shoots in a regular manner to thirty or forty feet high, having its young twigs covered with a smooth, light-brown bark, while those of the older are of a darker color. The leaves are of a lucid green, and grow irregularly on the young branches, on long foot-stalks: they resemble those of the common maple in figure; the lobes are all serrated; and from the base of the leaf a strong mid-rib runs to the extremity of each lobe that belongs to it. The flowers are of a kind of saffron color: they are produced at the ends of the branches in the beginning of April, sometimes sooner; and are succeeded by large round brown fruit, which looks singular. Both species may be propagated either by seeds or layers; but the first method is the best. 1. The seeds arrive from America in spring. A fine bed, in a warm well-sheltered place, should be prepared. If the soil be sandy, it should be wholly taken out nearly a foot deep, and the vacancy filled up with earth taken up a year before from a fresh pasture with the sward, well rotted and mixed by being often turned, and afterwards mixed with a sixth part of drift or sea-sand. In a dry day, early in March, let the seeds be sown, and the finest of this compost riddled over them a quarter of an inch deep. When the hot weather in spring comes on, the beds should be shaded and watered often, but in very small quantities. The plants being come up, shading should still be afforded them in summer, and a watering every other night; which will promote their growth, and render them

stronger by the autumn. In autumn the beds should be hooped, to be covered with mats in the severe frosts. These mats, however, should always be taken off in open weather. This is all the management they require during the first winter. The succeeding summer they only require weeding; though, if it should prove a dry one, they will need a little water now and then. By autumn they will be strong enough to resist the cold of the following winter, without the trouble of matting, if the situation is well sheltered; if not, it will be proper to have the hoops prepared, and the mats ready, against the northern frosts, which would endanger at least their losing their tops. After this, weeding only will be wanted; and in the spring following, that is, three years from their first appearance, they should be taken up, and planted in the nursery a foot asunder, and two feet distant in the rows. Hoeing the weeds in the rows in summer, and digging them in the winter, is all the trouble they will afterwards require until they are finally planted out. 2. They are easily increased by layers. The operation must be performed in autumn on the young summer's shoots; and the best way is by slitting them at a joint, as is practised for carnations. In a strong dry soil they will be often two years or more before they take root; though, in a fine light soil, they will be found to take freely enough. The leaves emit their odoriferous particles in such plenty as to perfume the circumambient air; nay, the whole tree exudes such a fragrant transparent resin, as to have given occasion to its being taken for the sweet storax. These trees, therefore, are very proper to be planted singly in large opens, that they may amply display their fine pyramidal growth, or to be set in places near seats, pavilions, &c. The resin was formerly of great use as a perfume.

138

LIRIA, an old town of Valencia, Spain, (the Carthaginian, Edera, and Roman Edeta), stands in a valley between two small hills. Its principal church is worth notice; it has two others; two convents, and a flourishing brandy distillery. Roman antiquities are frequently found. Twenty miles N. N. W. of Valencia.

LIRIODENDRON, the tulip-tree, in botany, a genus of the polygynia order, and polyandria class of plants, natural order fifty-second, coadunate: *CAL.* triphyllous; there are nine petals: *SEEDS* imbricated in such a manner as to form a cone. Species four, the principal one is,

L. tulipifera, a deciduous tree, native of America. It rises with a large upright trunk, branching forty or fifty feet high. The trunk, which often attains to a circumference of thirty feet, is covered with a gray bark. The branches, which are not very numerous, of the two-years-old wood, are smooth and brown; while the bark of the summer's shoots is smoother and shining, and of a bluish color. They are very pithy. Their young wood is green, and when broken emits a strong scent. The leaves grow irregularly on the branches, on long foot-stalks. They are of a particular structure, being composed of three lobes, the middlemost of which is shortened in such a manner that it appears as if it had been cut off and hollowed at the middle: the other

two are rounded off. They are about four or five inches long, and as many broad. They are of two colors; their upper surface is smooth, and of a stronger green than the lower. They fall off pretty early in autumn; and the buds for the next year's shoots soon after begin to swell and become dilated, insomuch that, by the end of December, those at the ends of the branches will become nearly an inch long and half an inch broad. The outward laminae of these leaf-buds are of an oval figure, have several longitudinal veins, and are of a bluish color. The flowers are produced with us in July at the ends of the branches: they somewhat resemble the tulip, which occasions its being called the tulip-tree. The number of petals of which each is composed, like those of the tulip, is six; and these are spotted with green, red, white, and yellow, thereby making a beautiful mixture. The flowers are succeeded by large cones, which never ripen in England. The propagation is very easy if the seeds are good; for by those which we receive from abroad, they are to be propagated. No particular compost need be sought for; neither is the trouble of pots, boxes, hot-beds, &c., required. They grow exceedingly well in beds of common garden mould, and the plants will be hardier and better than those raised with more care. Therefore, as soon as the seeds arrive, which is generally in February, and a few dry days have happened, so that the mould will work freely, sow the seeds, covering them three quarters of an inch deep; and observe to lay them lengthwise, otherwise, by being very long, one part, perhaps that of the embryo plant, may be out of the ground soon, and the seed be lost. This being done, let the beds be hooped; and as soon as the hot weather and drying winds come on, in spring, let them be covered from ten A. M. till sunset. If little rain happens, they must be duly watered every other day; and by the end of May the plants will come up. Shade and watering in the hottest summer must be afforded them, and they will afterwards give very little trouble. The next winter they will want no other care than, at the approach of it, sticking some furze bushes round the bed, to break the keen edge of the black frosts, for it is found that the seedlings of this sort are very hardy, and seldom suffer by any weather. After they have been two years in the seed-bed, they should be taken up and planted in the nursery, a foot asunder, and two feet distant in the rows. After this the usual nursery care of hoeing the weeds, and digging between the rows in the winter, will suffice till they are taken up for planting out. The tulip-tree, in those parts of America where it grows common, affords excellent timber for many uses; particularly, the trunk is frequently hollowed, and made into a canoe sufficient to carry many people; and for this purpose no tree is thought more proper by the inhabitants of those parts. It may be stationed among trees of forty feet growth.

LIRIS, in ancient geography, a river of Italy in Campania, which it separated from Latium and falling into the Mediterranean; now called Garigliano.

LIRON (John), a learned Benedictine, who published two curious works: 1. *Bibliothèque des Auteurs Chartrains*. 2. *Les Aménités de la Critique*. He died in 1749.

LIS, or Lys (John Vander), a painter of history, landscapes, and conversations, born at Oldenburgh in 1570. He went to Haarlem to study under Henry Goltzius; and, as he was endowed with great natural talents, soon distinguished himself in that school. He adhered to the same style till he went to Italy; where, having visited Venice and Rome, he studied the works of Titian, Tintoretto, Paul Veronese, and Dominic Petti, so effectually, that he altered his manner entirely. He soon received marks of public approbation; and his compositions became universally admired. His subjects were sacred histories, or rural sports, marriages, balls, and villagers dancing, dressed in Venetian habits; all which he painted in a small as well as a large size. An excellent picture of his is Adam and Eve lamenting the death of Abel. His paintings are rare. He died in 1629.

LIS (John Vander), of Breda, an historical painter, born at Breda about 1601. He became a disciple of Cornelius Polenburg, whose manner he imitated with extraordinary exactness. His portrait painted by himself, formerly in the possession of Horace Walpole, esq., is described as being worked up equal to the smoothness of enamel.

LISBON, the ancient Olisippa, and Felicitas Julia, seems to have acquired the latter name from the beauty and salubrity of its situation and climate; for it is found to have 200 fine, and but eighty rainy days in the course of the year. The capital, and one of the most important ports of Portugal, it is situated on seven hills, in the province of Estremadura (Extrema Durii), and rises from the north bank of the Tagus, three leagues within the bar. Above Lisbon, the Tagus is navigable sixteen leagues, and might easily be made so ten leagues farther, to Alcantara, on the frontiers of Spain. As it has most to dread an attack by shipping, the banks of the river are lined with forts on both sides. The first met with, on entering the harbour, is Fort Lorenzo, or the Tower of Bugio, on a sand-bank, which serves as a prison for convicts. Fort St. Julian is on a rock on the north shore of the entrance, and Fort St. Antonio on the south. The quays along the river are described as surpassing any thing of the kind in London or Paris; and the coup d'œil of the city from a distant point of the river, especially in crossing it from the south-east, is most imposing and majestic. Its general form is that of a half moon, four miles from point to point, and about a mile and a quarter broad.

It is surrounded by old and useless walls, flanked with towers, and may be divided into the Old and New town, the latter being that part rebuilt since the earthquake of 1755. This part of the city is neat and regular, and its streets have sewers and footways on each side. In the Old, part of the streets are so narrow, that the sun is said never to shine on the pavement, except when passing the meridian. In the centre

of the city is a small citadel. It has three suburbs, Junqueira, Alcantara, and Campo Grande, to which may be added Belem, a pleasant town immediately adjoining the city on the west, which has long been the residence of the court.

The public buildings of this metropolis are numerous, but not distinguished as specimens of architecture. In all there are forty parish churches, ninety-nine chapels, seventy-five convents or monasteries, and several distinct hospitals: here are also thirteen squares, great and small. The best edifices are the patriarchal church, situated on an eminence at the north-east of the city; the royal monastery of Belem, built in 1500; the church of St. Roque, formerly belonging to the Jesuits; and the New Church, the largest structure erected since the earthquake of 1755. The royal hospital, and the palace of the inquisition, are also large and elegant buildings. Near the latter is the public walk, an oblong garden laid out in alleys; and farther to the north is one of the two theatres of Lisbon, with a square for bull fights. The greatest architectural curiosity, however, is the aqueduct to the north of the city, which, though not half a mile in length, passes in one part through a tunnel, in another across a defile. It is partly Roman, partly a Gothic work; the principal arch is of the width of 107 feet, and considered one of the finest specimens of the Gothic style in Europe. In the great earthquake the body of it withstood the shock unhurt, but the key-stone sunk several inches. The Lisbon academy of sciences was founded in 1779 by the duke of Lafões, and has an observatory and a good mathematical library. The geographical academy was founded in 1799; the college of nobles in 1761; the royal marine academy in 1779; the academia real das Guardas Marinhas, in 1782; and the royal academy of fortification in 1790. Except the geographical academy, these are all institutions for education, and have sometimes had professors of merit. There are various public libraries, which contain all the standard Spanish and Portuguese works; but are deficient, as indeed is the whole city, in foreign books. The collections of natural history, laboratories, observatories, and botanical gardens, mentioned in the State Calendar, are of little importance. The only newspaper of the country is the Lisbon Gazette; and the insipid *Almoirene de Petas* was very lately the only literary journal. The royal or St. Joseph's hospital is an excellent institution, in which the sick are carefully attended, irrespective of their nation or religion. The number of patients admitted in a year frequently amounts to 12,000 or 14,000. The founding hospital is also a noble charity.

Lisbon is one of the most commercial cities of Europe, having 200 mercantile houses, of which 150 are English, and its trade annually employs between 1000 and 1500 vessels. In 1790 there cleared out 967: viz. English 319; Portuguese 252; North American 75; and 321 of all other nations. In 1797 the numbers entered and cleared out were,

	Entered.	Sailed
English	533	466
Portuguese	300	309
Danes	218	229
Americans	154	161
Prussians	80	86
Hamburgers	43	43
Ragusans	22	23
Venetians	19	24
Bremeners	10	11
Genoese	9	13
Lubeck	9	10
Morocco	9	2
(Oldenburg	6	8
Neapolitans	4	3
Spaniards	3	4
Pappenburg	2	2
French	1	1
Imperial	1	1
Total 1423	1396	

This includes all the colonial and three-fourths of the foreign trade of the kingdom, which altogether is very backward in manufactures, both in the capital as well as in the provincial towns. Lisbon has, however, manufactures of gold, silver, and brass; silk, cotton, woollen, and linen; thread, stockings, and lace; leather, hats, soap, tobacco, and earthenware, on a small scale. To England the chief exports are the wines, known as Lisbon and Calcavella; lemons, oranges, and fruits; cork, wood, silk and wool. The principal imports from this country are woollens, calicoes, stockings, watches, trinkets, coals, hardware, copper, and lead. From Ireland, corn, flour, and salted provisions. To the north of Europe Lisbon exports wines, salt, fruits, and colonial produce; and receives as imports corn, hemp, flax, iron, timber, deal, stock-fish, pitch, tar, Russian and German linens. The exchange transactions are on a large scale.

The patriarch of Lisbon, generally a cardinal of the Roman consistory, takes precedence of all the ecclesiastics of Portugal, and is always first chaplain to the king. Ignorance and superstition pervade all classes of its inhabitants. Numbers are seen throughout the day kneeling and motionless before figures of the Virgin, or of our Saviour on the cross, hung against the walls, and furnished on festival days with lamps. The streets, though less dirty than formerly, are still offensive to English visitors. At night, however, they are tolerably lighted, and the police regulations are good, but ill executed: assassinations and robberies being frequently committed in lonely parts of the city. Even in the day, the appearance of Lisbon is lifeless and cheerless, the Portuguese having little of the activity of their forefathers in business or amusement.

The Moors seem to have given the name *Lisboa* or *Lisboa* to this city when they conquered it with the rest of Portugal in the year 716. In the subsequent wars between them and the Christians, it was alternately lost and won by each, and continued many ages a sea-port of consequence, but did not become the capital of the kingdom until the beginning of the sixteenth century, when king Emanuel first made it a

VOL. XIII.

royal residence, and the central port for the expeditions to the East and West Indies.

It was unmolested by the demon of war from this period until the late French invasion of Portugal; but was partially shaken by the earthquake of 1531, and almost annihilated by that of 1755. See our article *EARTHQUAKE*. Ruins of its ravages are still visible. In 1807 the French army marched from Abrantes on this devoted capital, which afterwards became the scene of various important operations both of the British and French, until the latter abandoned it after the convention of Cintra. Mr. Southey's description of these events is so picturesque and interesting, that our readers, we are sure, will find it acceptable in this place.

The dismay and astonishment of the Lisbonians may well be conceived, when they learnt that the French were at Abrantes, and saw the court making ready for immediate flight. The hurry and disorder of Junot's march was not unknown; his artillery had been damaged, having been dragged by oxen and peasantry over mountainous roads; a great number of his horses had died upon the way over worked, and the men themselves had been marched so rapidly, and fed so ill, that a large proportion of them were more fit for the hospital than for active service. The greater part of the Portuguese army was near the capital, and, wretched as the state was to which it had fallen, neither the will nor the courage of the men was doubted. The English in the fleet, with a right English feeling, were longing to be let loose against the enemy: Sir Sidney offered to bring his ships abreast of the city, and there, seconded by the indignant populace, dispute every inch of ground with the invader: 'Surely,' he said, 'Lisbon is as defensible as Buenos Ayres!' Well might he thus feel and express himself who had defended Acre: and certain it is that Junot and all his foremost troops might have been put to the death which they had already merited at the hands of the Portuguese, if the prince had given the word. But such an act of vengeance, just as it would have been, would have been advantageous to Buonaparte, by giving him a colorable pretext for treating Portugal as a conquered country: this the prince knew; and it was in reliance upon his gentle and conscientious character that Junot advanced in a manner which would else have appeared like the rashness of a madman.

The Portuguese navy was ill equipped for sea; no care had been taken to keep it victualled, and it was now found that many of the water-casks were rotten, and new ones were to be made. The morning of the 27th had been fixed for the embarkation (of the royal family), and at an early hour numbers of both sexes and of all ages were assembled in the streets and upon the shore at Belem, where the wide space between the river and the fine Jeronymite convent was filled with carts and packages of every kind. From the restlessness and well-founded alarm of the people, it was feared that they would proceed to some excess of violence against those who were the objects of general suspicion. The crowd however was not yet very great when the prince appeared, both because of the distance

D

from Lisbon, and that the hour of embarkation was not known. He came from Ajuda, and the Spanish Infante D. Pedro in the carriage with him; the troops who were to be on duty at the spot had not yet arrived, and, when the prince alighted upon the quay, there was a pressure round him, so that, as he went down the steps to the water-edge, he was obliged to make way with his hand. He was pale and trembling, and his face was bathed in tears. The multitude forgot for a moment their own condition in commiseration for his; they wept also, and followed him, as the boat pushed off, with their blessings. There may have been some among the spectators who remembered that from this very spot Vasco de Gama had embarked for that discovery which opened the way to all their conquests in the east; and Cabral for that expedition which gave to Portugal an empire in the west, and prepared for her prince an asylum now when the mother country itself was lost.

‘In the course of the day the advanced guard (of the French) arrived in the immediate vicinity of the city, and Junot himself saw the ships with that prey on board in the hope of which he had advanced with such rapidity, conveying the family of Braganza beyond his power, and beyond that of his mighty master. The troops arrived without baggage, having only their knapsacks, and a half gourd slung from the girdle as a drinking-cup; their muskets were rusty, and many of them out of repair; the soldiers themselves mostly barefoot, foundered with their march, and almost fainting with fatigue and hunger. The very women of Lisbon might have knocked them on the head. Junot reached Sacavem between nine and ten at night. The next morning the royal guard of police went on to meet him at an early hour. Without halting in Lisbon, he hurried on to Belem, and, entering the battery of Bom-successo, satisfied himself by ocular demonstration that the Portuguese squadron was beyond his reach; he fired, however, upon those merchant-ships, which, not having been ready in time, were now endeavouring to escape. Very many were thus detained, for the prince’s order to spike the guns had only been partially obeyed, having been countermanded by the governors; and this was another of their acts for which the people could assign no adequate or excusable cause. Junot immediately sent a battalion to garrison Fort St. Juliens, and then returned to Lisbon, with hardly any other guard than some Portuguese troops whom he had met on the way and ordered to follow him; thus accompanied he paraded, as in triumph, through the principal streets. It was raining heavily, yet the streets were filled with a melancholy and wondering crowd. The shops were shut, the windows and verandas full of anxious spectators. The gestures of all those who saluted him as he passed, either for former acquaintance, or flattery, or fear, he returned with studied courtesy and stateliness. In this manner he proceeded to the house of Barao de Quintella, in the Rua d’Alegria, one of the most opulent of the Portuguese merchants. The palace of Bemposta had been prepared for him, and the Senado da Camera assigned for his household expenses a monthly contribution of 12,000 cru-

zados. He received the money, and compelled Quintella to be at the whole charge of his establishment.’

Our author’s description of the embarkation of the French, under Junot, is too long for insertion: but it forms an important record in illustration of the character of the French army at this period, and is closely connected with the history of this city. Speaking of the memorable convention, already alluded to, he says, ‘During the negotiation Lisbon was in a dreadful state. Those wretches who, to the reproach of Christian states and civilised society, are bred in the corruption of all great cities, took advantage of the temporary dissolution of government as they would have done of a conflagration or an earthquake. The soldiers of the police, being Portuguese, had almost all gone to join their countrymen in arms, and the French, while they went the rounds, suffered robberies to be committed in their hearing and in their sight, either not understanding the cries for help, or not choosing to interfere, now that their reign was at an end. They indeed themselves were in such danger that they soon gave over patrolling the streets, and fired upon those who approached their quarters in the night. In this manner several Portuguese were shot; the French venturing upon this, not so much in the confidence of their own strength, as in full reliance upon the interference of the English to protect them.

‘The French continued that system of public and private robbery for which they seemed to think the convention had granted them entire impunity. General Freire complained to Sir Hew Dalrymple that they were plundering the treasury, the museum, public libraries, arsenals, churches, and the houses and stores of individuals. The British commissioners for carrying the convention into effect, major-general Beresford and lord Proby, informed him, that except the military and naval stores there was no kind of public property which the French intended to relinquish; that they meant to carry off the valuables of the prince, the plunder of the churches, and much of the property of individuals; that they had packed up the royal library, and most of the articles of the museum: that during the negotiation they had taken a sum of about £22,000 from the Deposito Publico, which was in fact a robbery of individuals, that money being deposited there till litigations concerning it should be decided: and that even after the terms were signed they had actually demanded the money arising from the revenues of the country. The merchants of Lisbon addressed a memorial to the British commander, stating that Junot had exacted from them a forced loan of 2,000,000 cruzados, promising that payment should be made out of the enormous war-contribution which he had imposed, they had not been paid, and it was now his intention to depart without paying them; they therefore prayed for redress, and likewise that some steps should be taken for recovering their ships and property which had been unlawfully sequestered in France. There was something absolutely comic in the impudent persuasion of the French that they might continue to pillage and carry off what they pleased, under protection

of the British army. They proposed to take away the Vasco de Gama and some Portuguese frigates: the Gama, it may be remembered, was the ship wherein they had embarked great part of the treasure which they had collected. The reply was, that these vessels did not belong to them, and they were only to carry away their individual baggage. Junot actually demanded five ships to remove his own personal effects. Such a demand was of course pronounced to be inadmissible.

The first division of the French embarked under protection of the second, the second and third were protected by the British troops from the fury of the Portuguese. Wholly to restrain it was impossible, but no serious injury was done. They embarked amid the curses of the people. Nine days and nights the rejoicings continued, not by any order from the magistracy, but by the voluntary act of the inhabitants, whose joy was in proportion to the misery from which they had been delivered. It was a joy which thousands whose fortunes had been ruined, in the general calamity, partook; and which brought the last earthly consolation to many a broken heart. The enemy, while they lay in the river, were within sight of the illuminations and fire-works, and could hear the bells with which that great city rang from side to side. However brave in arms, however skilful in negotiation, they departed under circumstances more reproachful than had ever before attached to any army, or body of military men.

Lisbon is 313 miles west by south of Madrid, and contains a population of 240,000 inhabitants.

LISBON, NEW, a post town and the capital of Columbiana, a county of Ohio, on a branch of the Little Beaver. It is thirty-five miles south of Warren, thirty-four north of Steubenville, and fifty-six north-west of Pittsburg. It is a very flourishing town, and contains a court-house, a jail, a bank, a public library, a printing office, and two brick meeting-houses. In the vicinity of the town there are four merchant, and several other mills, a paper mill, a furnace, and a woollen manufactory.

LISBURN, a borough of the county of Antrim, Ireland, standing on the river Lagan, eight miles south-west of Belfast, and seventy miles north-east of Dublin. It has altogether a handsome appearance, and a considerable manufacture of linens. The damask table linen manufacture is particularly distinguished by the quality of the cloth, and the beauty of the patterns: muslin and cambric are also made. It sends one member to parliament.

LISIEUX, a considerable town of France, in the department of Calvados, and late province of Upper Normandy, seated at the confluence of the Orbeck and Gassey. The churches and public buildings are very handsome; but many of the houses are of wood. The cathedral has been much admired, and the gardens and cascades of the episcopal palaces. Here are manufactures of linen, flannel, cotton, and cyder: but the chief occupation of the neighbourhood is rearing cattle for the Paris market. It is thirty miles east of Caen, fourteen from the channel and 116 west of Paris.

LISLE or LILLE. See LILLE.

LISLE (Claudius de), a learned historiographer, born at Vancouleurs, in 1644. He studied among the Jesuits at Pontamousson; took his degrees in law, and afterwards studied history and geography; and to perfect himself in those sciences went to Paris, where the duke of Orleans, afterwards regent, and the principal lords of the court, became his scholars. He wrote, 1. An Historical Account of the kingdom of Siam. 2. A Genealogical and Historical Atlas. 3. An Abridgement of Universal History. He died at Paris in 1720.

LISLE (William de), son of the above, and the most learned geographer France has produced, was born at Paris in 1675. He became first geographer to the king, royal censor, and member of the academy of sciences. He died in 1726. He published a great number of excellent maps, and wrote many pieces in the Memoirs of the Academy of Sciences.

LISLE (Sir John), a brave loyalist in the time of the civil wars, was the son of a bookseller in London, and was educated in the Netherlands. He signalised himself upon many occasions, particularly in the last battle of Newbury; where, in the dusk of the evening, he led his men to the charge in his shirt, that his person might be more conspicuous. The king, who was an eyewitness of his bravery, knighted him in the field of battle. In 1648 he was one of the royalists who so obstinately defended Colchester, and who suffered for the defence of it. Having tenderly embraced the corpse of Sir Charles Lucas, his departed friend, he immediately presented himself to the soldiers who stood ready for his execution. Thinking that they stood at too great a distance, he desired them to come nearer: one of them said, 'I warrant you, sir, we shall hit you!' He replied with a smile, 'Friends, I have been nearer you when you have missed me.' He was executed August 28th 1648.

LISLE (Joseph, Nicholas de), a celebrated French astronomer born at Paris in 1688. He was the intimate friend of Newton and Halley, and was a member of most of the learned academies in Europe. In 1726 he was invited to Russia, and remained there till 1747. His principal work is his Memoirs of the History of Astronomy. Unlike many of the French philosophers, he joined unaffected piety to the love of science. He died in 1768.

LISMORE, a town of Waterford, Ireland, formerly a considerable city, and anciently called Dunsille; both Lis and Doone signifying a Danish mount, of which nature is the round hill of Lismore. It stands on the river Blackwater, over which it has a fine bridge, the span of the principal arch being 102 feet. The bishop's see was founded here in the seventh century, but united, in 1536, with the see of Waterford. The cathedral is spacious and handsome. Lismore castle was burned in the Irish war, in 1645; the duke of Devonshire has rebuilt it, in its ancient style, magnificently; an example imitated by Richard Edward Gumbleton, esq., who rebuilt Castle-Richard, situated upon the river's bank, three miles from Lismore, according to an elec-

gant Gothic elevation, at an expense of many thousand pounds. There is a considerable salmon fishery here. It is thirty-one miles W. S. W. of Waterford, and 100 S. S. W. of Dublin.

LISMORE, one of the Hebrides, or Western Islands of Scotland, seated at the mouth of Loch-Linnhe, or a capacious lake in Argyllshire, navigable for the largest ships to Fort William. This island is ten miles long, and from one to two miles broad. It abounds in limestone. Its population in 1791 was 1121. It is now not above 1350. It was anciently the residence of the bishops of Argyll, and gives name to the extensive parish in which it lies. It formerly abounded with deer, and elks' horns of a large size have been discovered in it. It was frequented by Fingal and his heroes, if such there were, of whom relics are still pointed out. Oats, barley, and flax, are the chief articles of cultivation. The church was once the chancel of its cathedral.

LISNE, *n. s.* Barb. Lat. *licia*, an enclosure. A cavity; a hollow.

In the *time* of a rock, at Kingscote in Gloucestershire, I found a bushel of petrified cockles, each near as big as my fist. *Hale.*

LISP, *v. a. & n. s.* Sax. *slipp*; Teut. *lispen*, *n. s.* *spen*; Belg. *lespen*. To speak with imperfect appulses of the tongue to the teeth or palate: to speak imperfectly in any way. See the extract from Holder.

Farewel, Monsieur Traveller; look you *lisp*, and wear strange suits; disable all the benefits of your own country. *Shakspeare.*

Come, I cannot cog, and say, thou art this and that, like a many of these *lisp*ing hawthorn buds, that come like women in men's apparel, and smell like Bucklersbury in simpling time. *Id.*

Scarce had she learnt to *lisp* a name Of martyr, yet she thinks it shame Life should so long play with that breath, Which spent can buy so brave a death. *Crashaw.*

They ramble not to learn the mode, How to be drest, or how to *lisp* abroad. *Clarendon.*

Appulse partial, giving some passage to breath, is made to the upper teeth, and causes a *lisp*ing sound, the breath being strained through the teeth.

Holder's Elements of Speech.

I overheard her answer, with a very pretty *lisp*, O! Strophon you are a dangerous creature. *Tatler.*

As yet a child, nor yet a fool to fame, I *lisp*ed in numbers, for the numbers came. *Pope.*

Pleased with the distant roar, with quicker tread, Fast by his hand one *lisp*ing boy she led. *Darwin.*

LISSA, a large town of Prussian Poland, on the borders of Silesia, was principally peopled by the Protestants who fled, in the seventeenth century, from the persecutions in Silesia, Bohemia, and Moravia. It now consists, for the greater part, of wooden buildings; and it has accordingly suffered severely from fire. It has a palace belonging to prince Sulkowski, the chief proprietor; a Catholic, and a Lutheran church, two Calvinist churches, a gymnasium, and a synagogue. Of the inhabitants (7600) one-half are Jews, and they have the greatest part of the trade. The articles of commerce are woollens;

the manufactures furs, hardware, and wines. Forty-four miles S. S. W. of Posen, and sixty-five west of Kalisch.

LISSA, an island on the coast of Dalmatia, in the gulf of Venice. It is hilly, and thinly peopled; but has a good fishery, and produces wine, olives, almonds, and figs. It has also a good harbour. Its ancient town of Issa is now a mere village. Lissa, in 1807, was occupied by the British; but, in 1810, it was taken by a French flotilla from Ancona. Fifty-six miles west of Ragusa.

LISSUS, in ancient geography, the last town of Illyricum, towards Macedonia, situated on the Drino. It had a capacious port, the work of Dionysius the tyrant, who led the colony thither, and enlarged and walled it round.—Diodorus Siculus. It is now called Alessio, in Albania.

LISSUS, a river of Thrace, running into the Ægean Sea, between Thasos and Samothrace, which was dried up by the army of Xerxes, when he invaded Greece.—Strabo, lib. 7.

LIST, *n. s. & v. a.* Fr. and Dan. *liste*; Goth. *lest*, *leit*, to speak or read. Thomson. A roll; catalogue; enrolment; hence a limit or bound: to enrol; register; hence to engage or retain for military service.

He was the ablest emperor of all the *list*. *Bacon.*

The lords would, by *listing* their own servants persuade the gentlemen in the town to do the like. *Clarendon.*

Some say the loadstone is poison, and therefore in the *lists* of poisons we find it in many authors. *Browne.*

The king who raised this wall appointed a million of soldiers, who were *listed* and paid, for the defence of it against the Tartars. *Temple.*

They *list* with women each degenerate name, Who dares not hazard life for future fame. *Dryden.*

For a man to give his name to Christianity, in those days, was to *list* himself a martyr, and to bid farewell not only to the pleasures, but also to the hopes of this life. *South.*

Bring next the royal *list* of Stuarts forth, Undaunted minds, that ruled the rugged north. *Prior.*

He that is born is *listed*; life is war; Eternal war with woe. *Young.*

LIST, *n. s. & v. a.* Fr. *lice*; Ital. *lizza*; Span. and Port. *liza* (*alizer*, Span., is to make even or smooth). An enclosed and prepared field of combat or exercise: to enclose ground for such purposes.

But telleth me what mistere men ye ber, That ben so hardy for to fighten here Withouten any jage or other offiere, As though it were in *listes* really. *Chaucer. Cant. Tales.*

The ocean, overpeering of his *list*, Eats not the flats with more impetuous haste, Then young Laertes in a riotous head, O'er-bears your officers. *Shakspeare. Hamlet.* She within *lists* my ranging mind hath brought, That now beyond myself I will not go. *Duval.* How dares your pride presume against my laws, As in a *listed* field to fight your cause? Unasked the royal grant. *Dryden's Knight's Tales.*

Paris thy son, and Sparta's king advance, In measured *lists* to toss the weighty lance:

And who his rival shall in arms subdue,
His be the dame, and his the treasure too. *Pope.*

LIST, *n. s. & v. n.* Sax. *lyrean*; Goth. *lysta*.
Desire; choice; willingness: to choose; desire;
incline.

To fight in field, or to defend this wall,
Point what you *list*, I nought refuse at all.

Faerie Queene.
Let other men think of your devices as they *list*, in
my judgment they be mere fancies. *Whitgylfe.*

Unto them that add to the word of God what them
listeth, and make God's will submit unto their will,
and break God's commandments for their own tra-
dition's sake, unto them it seemeth not good.

Hooker.

Alas, she has no speech!

—Too much;

I find it still when I have *list* to sleep.

Shakespeare.

Nothing of passion or peevishness, or *list* to con-
tradict, shall have any bias on my judgment.

King Charles.

I first adventure; follow me who *list*,

And be the second English satirist. *Bp. Hall.*

Kings, lords of time, and of occasions, may

Take their advantage when, and how, they *list*.
Daniel.

When they *list*, into the womb
That bred them they return; and howl, and gnaw
My bowels, their repast. *Milton. Paradise Lost.*

He saw false reynard where he lay full low;

I need not swear he had no *list* to crow. *Dryden.*

They sang as blithe as finches sing,

That flutter loose on golden wing,
And frolic where they *list*. *Couper.*

LIST, *n. s. & v. a.* } Fr. *lice*; Ital. *Span.*

LIST'ED, *adj.* } Port. and barb. Lat. *lis-*
ta; Swed. *list*; Belg. *lisse*. The border or limit
of a web, or piece of cloth; any border or margin;
a strip of cloth; to *list* is to sew together in
strips: hence *listed*; *striped*; *party-colored*. See
LIST, a roll.

They thought it better to let them stand as a *list*,
or marginal border, unto the Old Testament. *Hooker.*

A linen stock on one leg; and a kersy boot hose
on the other, gartered with a red and blue *list*.

Shakespeare.

Some may wonder at such an accumulation of
benefits, like a kind of embroidering or *listing* of one
favour upon another. *Wotton's Life of Buckingham.*

Over his head beholds

A dewy cloud, and in the cloud a bow

Conspicuous, with three *listed* colours gay,

Betokening peace from God, and covenant new.

Milton.

Instead of a *list* of cotton, or the like filtre, we
made use of a siphon of glass.

Boyle.

As the showery arch

With *listed* colours gay, or, azure, eyes,

Delights and puzzles the beholder's gale. *Phillips.*

A *list* the cobbler's temples ties,

To keep the hair out of his eyes. *Swift.*

LIST, *v. a.* } **LIST** is an abbrevia-
LIST'EN, *v. a. & v. n.* } tion of *listen*. Sax.
LIST'ENER, *n. s.* } *lyrean*; Dan. *lyste*;
LIST'LESS, } Gothic, *Maust*; Greck,
LIST'LESSLY, } *αλυσ*, to listen to. To
LIST'LESSNESS. } hearken; attend: *lis-*

ten, as a neuter verb, is to give attention; 'give
ear': a listener, a hearkeeper; generally used of
intruders and spies: *listless*, without attention;
careless; *heedless*; *languid*.

Listen, O isles, unto me, and hearken ye people.

Isaiah, xlix.

Who *list* unto this balades have inspection
Thinke that lov is lordship is excellent
Is remedy for disese and correccion
To woful herte. *Chaucer's Balades.*

Then weigh, what loss your honour may sustain,
If with too credent ear you *list* his songs;
Or lose your heart, or your chaste treasure open
To his unmastered importunity.

Shakespeare. Hamlet.

Lady, vouchsafe to *listen* what I say. *Shakespeare.*
One cried, God bless us! and Amen! the other
As they had seen me with these hangman's hands,
Listening their fear. I could not say, Amen! *Id.*

Listen to me, and if you speak me fair,

I'll tell you news. *Id.*

Antigonus used often to go disguised, and *listen*
at the tents of his soldiers; and at a time heard
some that spoke very ill of him: whereupon he said,
If you speak ill of me, you should go a little farther
off. *Bacon's Apophthegms.*

I, this sound I better know:

List! I would I could hear mo. *Ben Jonson.*

They are light of belief, great *listeners* after news.

Howel.

It may be the palate of the soul is indisposed by
listlessness or sorrow. *Taylor.*

The wonted roar was up amidst the woods,

And filled the air with barbarous dissonance,

At which I ceased and *listened* them a while.

Milton.

It [piety] is an employment most constant, never
allowing sloth or *listlessness* to creep in; incessantly
busying all our faculties with earnest contention.

Barrow.

Intemperance and sensuality clog men's spirits,
make them gross, *listless*, and unactive. *Tillotson.*

When we have occasion to *listen*, and give a more
particular attention to some sound, the tympanum is
drawn to a more than ordinary tension. *Holder.*

If your care to wheat alone extend,

Let Maja with her sisters first descend,

Before you trust in earth your future hope,

Or else expect a *listless*, lazy crop.

Dryden's Virgil.

On the green bank I sat, and *listened* long;

Nor till her lay was ended could I move,

But wished to dwell for ever in the grove.

Dryden.

Listeners never hear well of themselves.

L'Estrange.

To know this perfectly, watch him at play, and see
whether he be stirring and active, or whether he
lazily and *listlessly* dreams away his time. *Locke.*

If it is dangerous to be convinced, it is dangerous
to *listen*; for our reason is so much of a machine,
that it will not always be able to resist when the ear
is perpetually assailed. *Mackenzie.*

To this humour most of our late comedies owe
their success: the audience *listens* after nothing else.

Addison.

Lazy lolling sort

Of ever *listless* loiterers, that attend

No cause, no trust. *Pope.*

I was *listless* and desponding. *Gulliver's Travels.*

The hush word, when spoke by any brother in a
lodge, was a warning to the rest to have a care of
listeners. *Swift.*

Silence how dead! and darkness how profound!

Nor eye, nor *listening* ear an object finds;

Creation sleeps. *Young.*

At first he aims at what he hears,

And *listening* close with both his ears,

Just catches at the sound. *Couper.*

List!—'tis the bugle—Juan shrilly blow—
One kiss—one more—another—Oh! adieu!

Byron.

Who listens once will listen twice;
Her heart, be sure, is not of ice,
And one refusal no rebuff.

Id.

LIT, in commerce, the border of cloth or stuff: serving not only to show their quality, but to preserve them from being torn, in fulling, dyeing, &c.

LIT, in gardening, a border used by gardeners for securing their wall-trees.

LIT, in the tournament, was so called, as being hemmed round with pales, barriers, or stakes, as with a list. Some of these were double, one for each cavalier; which kept them apart, s. that they could not come nearer to each other than a spear's length. See **DUEL**, **TOURNAMENT**, and **BATTLE**.

TO LIST, or **ENLIST**, **SOLDIERS**. Persons listed either as volunteers, or by any kind of compulsion, must be carried within four days, but not sooner than twenty-four hours after, before the next justice of peace of any county, riding, city, or place, or chief magistrate of any city or town corporate (not being an officer in the army), and if before such justice or magistrate they dissent from such enlisting, and return the enlisting money, and also 20s. in lieu of all charges expended on them, they are to be discharged. But persons refusing or neglecting to return and pay such money, within twenty-four hours, shall be deemed as duly listed as if they had assented to it before the proper magistrate; and they shall, in that case, be obliged to take the oath, or, upon refusal, shall be confined by the officer who listed them till they do take it.

LISTER (Sir Matthew), M. D., physician to queen Anne of Denmark, queen of James VI., and to king Charles I., was president of the College of Physicians, and one of the greatest practitioners of his age. He died about 1637.

LISTER (Martin), M. D. and F. R. S., nephew to the preceding, was born in Bucks, in 1638, and educated at Cambridge. He afterwards travelled into France; and at his return practised physic at York, and afterwards in London. In 1683 he was created M. D., and became fellow of the College of Physicians in London. In 1698 he attended the earl of Portland in his embassy from king William III. to France; of which journey he published an account at his return, and was afterwards physician to queen Anne. He also published, 1. *Historia Animalium Angliæ*, 4to. 2. *Conchiliorum Synopsis*, folio. 3. *Cochlearum et Limachum Exercitatio Anatomica*, 4 vols. 8vo. 4. Many pieces in the Philosophical Transactions, and other works.

LITANA, or **LITANA SILVA**, in ancient geography, a wood of the Boii, in Gallia Togata, or Cispadana, where the Romans, under L. Posthumus Albinus, sustained a great defeat, scarcely ten escaping of 25,000, and their general's head being cut off by the Boii, and carried in triumph into their temple.—Livy. Holstenius supposes this happened above the springs of Scultenna, in a part of the Appennine, between Cersinianum and Mutina; now called Selva di Lugo.

LITANY, *n. s.* Gr. *λειτουργία*. Pezron derives this Greek word from the Celtic *lit*, a feast or solemnity. A form of prayer. See below.

Supplications, with solemnity for the appeasing of God's wrath, were, of the Greek church, termed *litanies*, and rogations of the Latin. *Hooker.*

There was never any church-liturgie but said *litanies* for their king and for their bishop! *Bp. Taylor.*

If our holy martyrs heretofore went to heaven with a *litaney* in their mouth, let not an ill-advised new-fangledness be suffered to put scorn upon that, wherein they thought themselves happy. *Bp. Hull.*

LITANY is derived from *λειτουργία*, I beseech, the expression repeated by the people in the service. At first litanies were not fixed to any stated time, but were only employed as exigencies required. They were observed with ardent supplications and fastings, to avert the threatening judgments of fire, earthquakes, inundations, or hostile invasions. About A. D. 400 litanies began to be used in processions, the people walking barefoot, and repeating them with great devotion. The days on which these were used were called rogation days; these were appointed by the canons of different councils, till it was decreed, by the council of Toledo, that they should be used every month throughout the year; and by degrees they came to be used weekly on Wednesdays and Fridays, the ancient stationary days for fasting. To these the rubric of the church of England has added Sundays. Before the last review of the Common Prayer the litany was a distinct service by itself, and used some time after the morning prayer was over; at present it is made one office with the morning service, being ordered to be read after the third collect for grace, instead of the intermissiual prayers in the daily service.

LITCHFIELD, a county of Connecticut, is bounded on the north by Massachusetts, east by Hartford, south-east by New Haven, south-west by Fairfield county, and west by New York.

LITCHFIELD, a post town, the capital of Litchfield county, in Connecticut, is situated thirty-eight miles N. N. W. of New Haven, and thirty west of Hartford. It contains a court house, a jail, a female academy, a law school, and two houses of public worship, one for Congregationalists, and one for Episcopalians, and has some trade. In the township there are nine houses of public worship; four for Congregationalists, four for Episcopalians, and one for Baptists. In the parish of South Farms there is another academy. It is a good agricultural town, and contains numerous mills and manufacturing establishments, among which are four forges for iron, a slitting-mill, nail manufactory, cotton manufactory, paper-mill, and five large tanneries. Mount Tom, on the western border of the town, is 700 feet high. There are four ponds in this town, the largest of which comprises 900 acres. There is a medicinal spring within half a mile of the court-house.

The law school in this town is a private institution, established upwards of thirty years since. It has two professors, and at present thirty-six or thirty-seven students. The members study the law by titles, in the order in which the lectures are given. The mode of instruction is by lec

ruring on the several titles of the law in an established order. The course of lectures occupies about fourteen or fifteen months. One lecture is given every day. There are two vacations of four weeks each; one in May, the other in October. The price of tuition is at the rate of 100 dollars a year, that of board from three dollars to three and a half a week.

Also a county of Ohio, on Lake Erie.

LITERAL, *adj.* & *n. s.* } *Fr. literal*; *Lat.*

LIT'ERALLY, *adv.* } *litera.* See LETTER.

LITERAL'ITY, *n. s.* } Following the letter;

according to the strict or primitive meaning; consisting of letters: literal, as a substantive, and literality, both signify original or primitive meaning.

The fittest for public audience are such as, following a middle course between the rigour of *literal* translations and the liberty of paraphrasts, do with greater shortness and plainness deliver the meaning.

Hooker.

No man puts out his right eye *literally*, or cuts off his right hand to prevent scandal. Certain it is, there hath been much greater inconvenience by following the letter of these words of institution, than of any other in Scripture.

Sp. Taylor.

How dangerous it is in sensible things to use metaphorical expressions unto the people, and what absurd conceits they will swallow in their *literals*, an example we have in our profession.

Broune.

Not attaining the true deuterocopy, and second intention of the words, they are fain to omit their superconsequences, coherences, figures, or tropologies, and are not sometimes persuaded beyond their *literalities*.

Broune's Vulgar Errors.

A foundation being primarily of use in architecture, hath no other *literal* notation but what belongs to it in relation to an house, or other building; nor figurative, but what is founded in that, and deduced from thence.

Hammond.

Endeavouring to turn his Nisus and Euryalus as close as I was able, I have performed that episode too *literally*; that giving more scope to Mezentius and Lausus, that version, which has more of the majesty of Virgil, has less of his conciseness.

Dryden.

That a man and his wife are one flesh, I can comprehend; yet *literally* taken it is a thing impossible.

Swift.

The *literal* notation of numbers was known to Europeans before the cyphers.

Johnson.

LITERARY, *adj.* } *Lat. literarius.* Re-

LITERA'TI, *n. s.* } specting or belonging

LIT'ERATURE, *n. s.* } to letters, learning, or the learned: literati is a substantive of Ital. origin, signifying the learned, or any number of learned men taken collectively: literature, learning; scholastic knowledge.

This kingdom hath been famous for good *literature*; and, if preferment attend deservers, there will not want supplies.

Bacon.

I shall consult some *literati* on the project sent me for the discovery of the longitude.

Spectator.

When men of learning are acted by a knowledge of the world, they give a reputation to *literature*, and convince the world of its usefulness.

Adison's Freeholder.

All hopes of new *literary* institutions were quickly suppressed by the contentious turbulence of king James's reign.

Johnson.

We, in Scotland, boast of our professors, that they give regular lectures in all the sciences, which

the students are obliged to attend; a part of *literary* economy which is but little attended to in the universities of England.

Beattie.

Hence a moderate pain, upon which the attention may fasten and spend itself, is to many a refreshment; as a *literary* controversy.

Paley.

As boys love rows, my boyhood liked a squabble;

But at this hour I wish to part in peace,

Leaving such to the *literary* rabble,

Whether my verse's fame be doomed to cease

While the right hand which wrote it still is able,

Or of some centuries to take a lease. *Byron.*

LITERARY PROPERTY. See COPYRIGHT.

LITERATI (letrados, lettered), an epithet given to such persons among the Chinese as are able to read and write their language. The literati alone are capable of being made mandarins. See CHINA.

LITERATI may also be considered as the name of a particular sect in religion or philosophy, consisting principally of the learned men of China. It is called the jukiao, i. e. learned sect. It had its rise A. D. 1400, when the emperor, to awaken the attention of the people to knowledge, which had been quite neglected during the civil wars, and to stir up emulation among the mandarins, ordered forty-two of their ablest men of learning to compose a body of doctrine agreeable to that of the ancients. The work, being composed by so many learned persons, and approved by the emperor, was received with great applause. Many were pleased with it because it seemed to subvert all religion; others approved it because the little religion that it left them could not give them trouble to regard it. The court, the mandarins, persons of fortune and quality, &c., are generally literati. They freely tolerate the Mahomedans, because they adore, with them, the king of heaven, and author of nature; they have an aversion, however, to all sorts of idolaters, and it was once resolved to extirpate them. See CHINA.

LITERATURE, as a branch of the fine arts, has been chiefly regarded as embracing the consideration of the effects of ELOQUENCE OR ORATORY, and of the structure and influence of POETRY. Both these arts are connected in their essence and end with the sister arts of music, painting, sculpture, and architecture; that essence being in the whole of them *expression*, and the end, pleasure.

Beauty, again, is the object with which all these arts are conversant; and words are admitted by Mr. Burke to have as considerable share in exciting the ideas of beauty and of the sublime as any of them; but he contends that words affect us in a very different manner to nature, or the other fine arts. 'The common notion,' he observes, 'is, that the power of poetry and eloquence, as well as that of words in ordinary conversation, is, that they affect the mind by raising ideas in it of those things for which custom has appointed them to stand; but their influence on the passions may be traced to a totally different source.' 'Nobody, I believe,' says this great man, 'immediately on hearing the sounds, virtue, liberty, or honor, conceives any precise notions of the particular modes of action and thinking, together with the mixt and

simple ideas, and the several relations of them for which these words are substituted; neither has he any general idea, compounded of them; for, if he had, then some of those particular ones, though indistinct, perhaps, and confused, might come soon to be perceived. But this, I take it, is hardly ever the case. For put yourself upon analysing one of these words, and you must reduce it from one set of general words to another, and then into the simple abstracts and aggregates, in a much longer series than may be at first imagined, before any real idea emerges to light, before you come to discover any thing like the first principles of such compositions; and, when you have made such a discovery of the original ideas, the effect of the composition is utterly lost. A train of thinking of this sort is much too long to be pursued in the ordinary ways of conversation, nor is it at all necessary that it should. Such words are in reality but mere sounds; but they are sounds, which being used on particular occasions, wherein we receive some good, or suffer some evil; or see others affected with good or evil; or which we hear applied to other interesting things or events; and being applied in such a variety of cases, that we know readily by habit to what things they belong, they produce in the mind, whenever they are afterwards mentioned, effects similar to those of their occasions. The sounds being often used without reference to any particular occasion, and carrying still their first impressions, they at last utterly lose their connexion with the particular occasions that gave rise to them; yet the sound, without any annexed notion, continues to operate as before.' 'I find it very hard,' he adds, 'to persuade several that their passions are affected by words from whence they have no ideas; and yet harder to convince them, that in the ordinary course of conversation we are sufficiently understood without raising any images of the things concerning which we speak. It seems to be an odd subject of dispute with any man, whether he has ideas in his mind or not. Of this, at first view, every man, in his own forum, ought to judge without appeal. But, strange as it may appear, we are often at a loss to know what ideas we have of things, or whether we have any ideas at all upon some subjects. It even requires a good deal of attention to be thoroughly satisfied on this head. Since I wrote these papers I found two very striking instances of the possibility there is, that a man may hear words without having any idea of the things which they represent, and yet afterwards be capable of returning them to others, combined in a new way, and with great propriety, energy, and instruction. The first instance is that of Mr. Blacklock, a poet blind from his birth. Few men blessed with the most perfect sight can describe visual objects with more spirit and justness than this blind man; which cannot possibly be attributed to his having a clearer conception of the things he describes than is common to other persons. The second instance is of Mr. Saunderson, professor of mathematics in the University of Cambridge. This learned man had acquired great knowledge in natural philosophy, in astronomy, and whatever sciences depend upon mathematical skill.

What was the most extraordinary, and the most to my purpose, he gave excellent lectures upon light and colors; and this man taught others the theory of those ideas which they had, and which he himself undoubtedly had not. But it is probable that the words red, blue, green, answered to him as well as the ideas of the color themselves for the ideas of greater or less degrees of refrangibility being applied to these words, and the blind man being instructed in what other respects they were found to agree or to disagree, it was as easy for him to reason upon the words, as if he had been fully master of the ideas. Indeed it must be owned he could make no new discoveries in the way of experiment. He did nothing but what we do every day in common discourse.'

Our author then instances, in passages from Virgil, Horace, and Milton, the manner in which he conceives we are affected by verbal description:—'There is not perhaps in the whole *Æneid* a more grand and labored passage than the description of Vulcan's cavern in *Ætna*, and the works that are there carried on. Virgil dwells particularly on the formation of the thunder, which he describes unfinished under the hammers of the Cyclops. But what are the principles of this extraordinary composition?

Tres imbris torti radios, tres nubes aquosæ
Addiderant; rutili tres ignis et alitis auri;
Fulgores nunc terrificos sonitumque, metumque
Miscebant operi, flammisque sequacibus iras.

This seems to be admirably sublime; yet, if we attend coolly to the kind of sensible images which a combination of ideas of this sort must form, the chimeras of madmen cannot appear more wild and absurd than such a picture. 'Three rays of twisted showers, three of watery clouds, three of fire, and three of the winged south wind; then mixed they in the work terrific lightnings, and sound, and fear, and anger, with pursuing flames.' This strange composition is formed into a gross body; it is hammered by the Cyclops, it is in part polished, and partly continues rough. The truth is, if poetry gives us a noble assemblage of words, corresponding to many noble ideas, which are connected by circumstances of time or place, or related to each other as cause and effect, or associated in any natural way, they may be moulded together in any form, and perfectly answer their end. The picturesque connexion is not demanded; because no real picture is formed; nor is the effect of the description at all the less upon this account.

'What is said of Helen by Priam and the old men of his council, is generally thought to give us the highest possible idea of that fatal beauty.

Οὐ νηϊστὶς Τρῶας καὶ ἑνὴν ἡμιδα Ἀχαιῶς
Τοιῇ δ' ἄμφω γυναικεὶ πόλυν χρωρὸν ἀλγέα πασχύν
Αἰνῶς δ' ἀθανάτοισι Στῆς εἰς ὤπα τοικυρ.

They cried, no wonder such celestial charms
For nine long years have set the world in arms;
What winning graces! what majestic mien!
She moves a goddess, and she looks a queen. Pope.

Here is not one word said of the particulars of her beauty; nothing which can in the least help us to any precise idea of her person; but yet we are much more touched by this manner of men-

tioning her than by those long and labored descriptions of Helen, whether handed down by tradition, or formed by fancy, which are to be met with in some authors. I am sure it affects me much more than the minute description which Spenser has given of Belphebe; though I own that there are parts in that description, as there are in all the descriptions of that excellent writer, extremely fine and poetical.'

'Certain it is, that the influence of most things on our passions is not so much from the things themselves, as from our opinions concerning them; and these again depend very much on the opinions of other men, conveyable for the most part by words only. Secondly, there are many things of a very affecting nature, which can seldom occur in the reality, but the words which represent them often do; and thus they have an opportunity of making a deep impression and taking root in the mind, whilst the idea of the reality was transient; and to some perhaps never really occurred in any shape, to whom it is notwithstanding very affecting, as war, death, famine, &c. Besides many ideas have never been at all presented to the senses of any men but by words, as God, angels, devils, heaven, and hell, all of which have, however, a great influence over the passions. Thirdly, by words we have it in our power to make such combinations as we cannot possibly do otherwise. By this power of combining we are able, by the addition of well-chosen circumstances, to give a new life and force to the simple object. In painting we may represent any fine figure we please: but we never can give it those enlivening touches which it may receive from words. To represent an angel in a picture, you can only draw a beautiful young man winged: but what painting can furnish out any thing so grand as the addition of one word, 'the angel of the Lord?' It is true, I have here no clear idea: but these words affect the mind more than the sensible image did; which is all I contend for. A picture of Priam dragged to the altar's foot, and there murdered, if it were well executed, would undoubtedly be very moving: but there are very aggravating circumstances, which it could never represent:

Sanguine fœdenter quos ipse sacraverat ignes.

As a farther instance, let us consider those lines of Milton, where he describes the travels of the fallen angels through their dismal habitation:

O'er many a dark and dreary vale
They passed, and many a region dolorous;
O'er many a frozen, many a fiery Alp;
Rocks, caves, lakes, fens, bogs, dens, and shades
of death.

A universe of death.—

Here is displayed the force of union in

Rocks, caves, lakes, dens, bogs, fens, and shades;
which yet would lose the greatest part of the effect, if they were not thus

Rocks, caves, lakes, dens, bogs, fens, and shades—
—of Death.

This idea or this affection caused by a word, which nothing but a word could annex to the others, raises a very great degree of the sublime;

and this sublime is raised yet higher by what follows, 'a universe of Death.' Here are again two ideas not presentable but by language; and a union of them great and amazing beyond conception; if they may properly be called ideas which present no distinct image to the mind:—but still it will be difficult to conceive how words can move the passions which belong to real objects, without representing these objects clearly. This is difficult to us, because we do not sufficiently distinguish, in our observations upon language, between a clear expression, and a strong expression. These are frequently confounded with each other, though they are in reality extremely different. The former regards the understanding; the latter belongs to the passions. The one describes a thing as it is; the other describes it as it is felt. We yield to sympathy what we refuse to description. The truth is, all verbal description, merely as naked description, though never so exact, conveys so poor and insufficient an idea of the thing described, that it could scarcely have the smallest effect, if the speaker did not call in to his aid those modes of speech that mark a strong and lively feeling in himself. Then, by the contagion of our passions, we catch a fire already kindled in another, which probably might never have been struck out by the object described: and words, by strongly conveying the passions, by those means which we have already mentioned, fully compensate for their weakness in other respects. It may be observed, that very polished languages, and such as are praised for their superior clearness and perspicuity, are generally deficient in strength. The French language has that perfection and that defect. Whereas the oriental tongues, and in general the languages of most unpolished people, have a great force and energy of expression; and this is but natural. Uncultivated people are but ordinary observers of things, and not critical in distinguishing them; but, for that reason, they admire more, and are more affected with what they see, and therefore express themselves in a warmer and more passionate manner. If the affection be well conveyed, it will work its effect without any clear idea; often without any idea at all of the thing which has originally given rise to it.'

These ideas suggest, at least, the basis on which the influence of literature on the character and manners of nations must rest. When oratory and poetry become distinct arts, they claim, of course, distinct discussion. See POETRY and ORATORY.

LITHANTHRAX, or pit coal, is a black or brown, laminated, bituminous substance; not very easily inflammable, but, when once inflamed, burns longer and more intensely than any other substance. See COAL. Of this substance three kinds are distinguished by authors. The residuum of the first, after combustion, is black; the residuum of the second is spongy, and like pumice stone; and the residuum of the third is whitish ashes. Some fossil coal, by long exposure to air, falls into a grayish powder; from which alum may be extracted. Fossil coal by distillation yields, 1, a phlegm or water; 2, a very acrid liquor; 3, a thin oil like naphtha; 4, a thicker

oil, resembling petroleum, which falls to the bottom of the former, and which rises with a violent fire; 5, an acid concrete salt; 6, an un-inflammable earth remains in the retort. These constituent parts of fossil coal are very similar to those of amber and other bitumens. From some sorts of it a varnish may be made by fat oils. Fixed alkali has never been found in any species of it; nor sulphur, unless when mixed with pyrites. None of the species are electric per se. For exciting intense heats, as in furnaces for smelting iron ore, and for operations where the acid and oily vapors would be detrimental, as in drying of malt, fossil coals are previously charred, or reduced to cokes. See COKE. Pit-coal affords tar, and, on that and other accounts, is ranked by modern chemists among vegetable substances.

LITHARGE. Fr. *litharge*; Lat. *lithargyrum*. Lead vitrified with copper.

Our orpiments and sublimed mercury,
Our grounden *litharge* eke on the porphurie,
Of eche of thise of unces a certain,
Not helpeth us; our labour is in vain.

Chaucer. *Cant. Tales*.

I have seen some parcels of glass adhering to the test or cupel as well as the gold or *litharge*. Boyle.

Litharge is properly lead vitrified, either alone or with a mixture of copper. This recement is of two kinds, *litharge* of gold, and *litharge* of silver. It is collected from the furnaces where silver is separated from lead, or from those where gold and silver are purified by means of that metal. The *litharge* sold in the shops is produced in the copper works, where lead has been used to purify that metal, or to separate silver from it. Hill.

Litharge of lead is often used in the analysis of the ores of what are called the perfect metals.

Parkes's *Chemical Catechism*.

LITHARGE is a preparation of lead, usually in form of soft flakes, of a yellowish reddish color. If calcined lead be urged with a hasty fire, it melts into the appearance of oil; and, on cooling, concretes into litharge. According to the degree of fire and other circumstances, it proves of a pale or deep color; the former called litharge of silver, the latter litharge of gold.

LITHE, *adj.* } Sax. *slithe*; Mæso-Goth.

LITH'ER, *adj.* } *litha*, to bend. Flexible; limber; soft; pliant.

When it was night, to slepe I laie,
Right as I was wont for to doen,
And fill aslepé wondir sone,
As he that was werie forgo
On pilgrimage milis two
To the corps of saint Leonarde,
To makin *lith* that erst was harde. Chaucer.

Thou antick death,
Two Talbots winged through the *lither* sky,
In thy despiht shall 'scape mortality.

Shakspeare.

The' unwieldy elephant,
To make them mirth, used all his might, and
wreathed
His *lithe* proboscis. Milton's *Paradise Lost*.

LITHIATE, from Gr. *λίθος*, a stone, a neutral salt, formed by the combinations of the lithic acid with various bases. See CHEMISTRY.

LITHIC ACID, an acid extracted from the urinary calculus. See CHEMISTRY.

LITHOGRAPHY, *n. s.* } Gr. *λίθος*, a stone.
LITHOMANCY, } Lithography is the
LITHONTRIP'TICK, } art of engraving or
LITHOT'OMY, } writing on stone:
LITHOT'OMIST. } lithomancy, Greek,

λίθος, a stone, and *μαννία*, divination; prediction by stones: lithontripstick, Fr. *lithontripitique*, a medicine that dissolves stones in the kidneys or bladder: lithotomy, Gr. *λίθος* and *τεμνω*, to cut, the art or practice of cutting for the stone: lithotomist, one who professes the art of extracting stones from the bladder.

As strange must be the *lithomancy*, or divination, from this stone, whereby Helenus the prophet foretold the destruction of Troy. Broune.

If it be certain that *lithotomy* is more likely to be followed by the patient's recovery, when no manual roughness is exercised, rapid operating must be condemned by the judicious and discerning.

Dr. A. Rees.

LITHOGRAPHY is the art of taking impressions from drawings made on stone. The general process consists in drawing the design upon the absorbent body with a soapy chalk, and in decomposing this soapy design by an acid, which, liberating the fatty matter present, greases the stone where the design existed, or rather brings it into such a state that, being wetted and then rolled with the ink-roller, no ink will adhere except at the parts underneath the original design. From this it will be obvious that the process depends entirely on chemical principles, and is thus distinct from letter-press or copperplate printing, which are altogether mechanical. On this account it has in Germany been called *chemical printing*; and, as metallic plates can be prepared to be printed from in a similar manner, lithography is considered only as a branch of chemical printing.

Alois Senefelder may be considered as the inventor of this beautiful art. His first professional essays were executed in 1796. The difficulty he experienced in writing backwards, led him to the process of transfer, and the use of dry soap, which was found to leave permanent traces, which would give impressions, naturally led to the mode of chalk-drawings. Having made considerable improvements, Mr. Senefelder obtained, in 1799, a patent privilege for Bavaria, when he made known his process, and afterwards entered into partnership with Mr. André, of Offenbach, who proposed to establish presses, and take out patents at London, Paris, and Vienna. For this purpose Senefelder came to London with a brother of André's, and the invention having been much spoken of, under the name of polyautography, most of the principal English artists made trials of it. Unfortunately, however, the art of printing from the stones was not then fully understood, and the difference between the materials of Germany and those of England, used both for the purposes of drawing and printing, caused constant failures, and the artists in succession abandoned the practice of it. To this cause is to be attributed the unpopularity of lithography in England, as it was left entirely in the hands of amateurs, whose productions, generally speaking, did no credit to the art, and

whose faults were in some degree supposed to be those of the art itself. In August, 1800, Senefelder, who had now separated from André, went to Vienna, where, after much difficulty, a patent was obtained, and extensive preparations were made, for applying his process to print cottons; but bad management, and some unfortunate circumstances, prevented his success, and he returned to Munich in 1806, leaving the establishment in other hands.

Mr. Mitterer, professor of drawing at the public school at Munich, now (1806), practised lithography to multiply copies for the pupils, and is said to have invented the chalk composition in its present form, or at least to have improved it greatly. From this period the practice of the art has extended and improved rapidly, and more particularly at Munich, where several establishments were formed, for the purpose of applying it to the fine arts, as well as for printing writings and official forms, for the different departments of the government.

In October, 1809, Senefelder was appointed inspector of the Royal Lithographic Establishment at Munich, for printing from stone a complete map and survey of Bavaria, since which period he has devoted his time to experiments, and to writing the history of his invention. Among other points of improvement, to which his attention has been directed, is a substitute for the stones, which are inconvenient to use on account of their weight, and they are also liable to break in the press, when used without due caution, or when they contain flaws. For this purpose he has made a composition of drying oil, finely ground earth, and other substances, which is thinly spread over pieces of parchment; but it has not hitherto been found to answer. The surface cracks after repeated wetting and exposure to the power of the press, and the printing ink is then taken in the cracks and spoils the impressions. Thus a very small number only of good impressions can be obtained.

From the period of André's English patent, till Mr. Hullmandel commenced his establishment in London, but little progress was made in this country; but that ingenious artist formed a new era in lithography, and in many cases English printing is now equal, if not superior, to the continental works.

The principal operation in lithography consists in *impregnating* a stone with fatty substances, very superficially, so that, in consequence of the affinity which exists between these substances and their power to repel water, the points or lines formed with them on stone shall be capable of retaining other such substances whenever they are brought in contact with them; while these substances will be repelled by the moisture which the stone has imbibed in those parts which they do not cover. Thus, when lines have been made on a stone with lithographic ink, or crayons, into the composition of which fatty bodies enter, and afterwards a roller charged with a fat or oily ink is passed over these stones, this ink will be deposited on the traces of the crayon, or of the lithographic ink, in a thin layer, but sufficient to produce an impression; whilst it will not adhere to any parts of the stone which are not

impregnated with the fatty matter; and which, besides, are kept in a moist state. It is on this point that all the art of lithography depends; and it is only requisite, therefore, to discover what substances, by a proper combination, can be made most suitable to answer the double purpose of producing a good drawing, and of receiving the ink, which is to form the impression. It will be apparent that it is not a matter of indifference what kind of fatty substance is used with which to form, a drawing, or to trace a writing, on the stone. These substances, in their natural state, if brought into contact with a stone, would diffuse themselves in every direction; and, consequently, would not be capable of forming points or lines sufficiently fine and well defined, to give to a drawing the delicacy, precision, and harmony, which it ought to have. It is necessary, then, to find a liquid composition, by which may be traced lines as clear and well defined as those made on paper with Indian ink; and also a solid preparation, which will produce the same results as the common crayons used by artists. Hitherto, it has only been possible to effect this by forming a kind of soap, by the combination of fatty or resinous substances with an alkali. This soap, when liquid, does not spread as grease and oils do; and, when in a solid state, it has such a degree of consistency as to enable the artist to produce upon stone all the effects of a drawing. But as soapy bodies are, in general, soluble in water, and as the water with which it is necessary to moisten the stone, and consequently the drawing, before applying the printing-ink, would destroy the drawing, by dissolving the soapy substance with which it was formed, it was found necessary to find a means of reducing this soap to the state of a fatty body insoluble in water. This is effected by spreading over the stone and over the drawing an acid, which, by uniting with the alkali of the soap, reduces the latter to the state of grease. This operation is called the preparation.

Lithographic ink, if good, will be soluble in distilled water, which is capable of perfectly dissolving common soap. It ought to flow freely from the pen, and not spread on the stone; it must also be capable of forming extremely fine lines, and should be very black, in order to render the work of the artist perfectly clear and distinct. The most essential quality, however, is that of imbedding itself firmly in the stone, so as to reproduce the most delicate touches of the drawing, and to afford a great number of impressions: in order to do this, it is necessary that it should be capable of resisting the acid which is spread over it in the preparation, so as not to have its fatty particles either removed or altered. A host of recipes, for making lithographic ink and crayons, have been published, and scattered both in Germany and France. M. Senefelder, in his work, gives eight receipts for making this drawing-ink; yet, assuredly, he has not published that which he considers the best. We think it superfluous to give these receipts, as it would only serve to create uncertainty in choosing from among them, and especially as they are all considered more or less inferior to the following:—

	Drachms.
Soap, from suet or tallow, dry . . .	30
Mastic, in tears	30
Soda of commeree	30
Shell-lac	150
Fine lamp-black	12

Soap made of tallow is to be preferred to that prepared from oil. But as soap is more or less hard, according to its age and the dryness of the situation in which it has been kept, it must not be used in exactly the above proportions with the other articles, without regard to its being either moist or dry. To obviate this source of error, and to obtain the exact proportions, the soap should be cut with a knife into thin slices, and exposed to the sun and air until it is perfectly dry; it is then to be put into a box lined with paper, and thus kept in a very dry place until it is wanted for use. The best lamp-black, which is the product of the combustion of resin, should be used.

In order to melt these materials, a copper, cast-metal skillet, should be used, which should be furnished with a wooden handle; it will also be found convenient for it to have a lip on its edge, in order that the material may pass more readily into the moulds, particularly when crayons are to be made. The soap is first put into this vessel, which is then to be placed over a brisk fire in a chafing-dish; when this is well melted the shell-lac is to be thrown in, which will fuse very readily; the soda is then to be added, a little at a time, and after this the mastic, taking care to stir it with a spatula, furnished with a wooden handle; lastly, the lamp-black is gradually put in, stirring it between every successive addition until the mixture is complete. A very brisk fire is used that the materials may be perfectly fused. The shell-lac is apt to swell up; it is, therefore, put into the skillet gradually that it may not boil over. When all these materials are well incorporated, they are poured out on a plate of cast-iron, made very warm and rubbed over with oil, in order that the composition may be easily detached from it. Before the mass is poured on the plate, ledges are formed round it with pieces of wood, which serve to prevent the mass from running off, and enable us to preserve it of an equal thickness throughout; when these pieces of wood are removed, the composition is to be cut into stripes by means of a knife, which should be guided by a straight ruler; this must be done whilst the composition is warm. Little sticks are thus formed, similar to those of Indian ink; it would, however, be more convenient to have moulds in which to pour the composition.

Many who have written on the subject of lithography have recommended, not merely the melting, but the partial burning of the materials with which lithographic ink and crayons are to be composed; but this is a bad method, since it is impossible in this way always to obtain the same combinations, as some portion of the materials would thus be wholly destroyed. The means of obtaining good ink must depend on the nature of the materials, and upon their being duly proportioned to each other, and, to accom-

plish these ends, it is not necessary to have recourse to combustion.

The ink, of which we are about to give the composition, is used either with the pen or the camel's hair pencil, for writings, dotted, and aquatinta drawings, those of a mixed character, or those intended as imitations of wood or other engravings.

We proceed to describe, practically, the process for preparing the autographic ink, or the kind which is suitable for transferring to stone the writings or drawings which have been executed on paper, prepared for that purpose.

This ink ought to be mellow, and somewhat thicker than that used immediately on the stone so that, when it is dry on the paper, it may still be sufficiently viscous to cause it to adhere to the stone by simple pressure. The following is the manner of preparing the ink:—

	Drachms.
Dry soap	100
White-wax, free from tallow . . .	100
Mutton suet	50
Shell-lac	50
Mastic	50
Lamp-black	30 to 35

These materials are to be melted in the way we have described for lithographic ink.

The operation, by which a writing or drawing is transferred from paper to stone, not only affords the means of abridging labor, but also of producing the writings or drawings in the same direction in which they have been traced; whereas, when they are executed immediately on stone, they must be performed in a direction opposite to that which they are eventually to have. Thus it is necessary to draw those objects on the left, which, in the impression, are to be on the right hand. To acquire the art of reversing subjects, when writing or drawing, is both difficult and tedious; while by the aid of transparent, and of autographic, paper, impressions may be readily obtained, in the same direction as that in which the writing or the drawing has been made. In order to make a transfer to stone of a writing or drawing, in lithographic ink or in crayons, or an impression from a copper-plate, it is necessary, first, that the drawing, or transcript, should be on a thin and flexible substance, such as common paper; secondly, that it should be capable of being easily detached from this substance, and transferred entirely to the stone, by means of pressure. But as the ink with which a drawing is traced penetrates the paper to a certain depth, and adheres to it with considerable tenacity, it would be difficult to detach them perfectly from each other, if, between the paper and the drawing, some substance were not interposed, which, by the portion of water it is capable of imbibing, should so far lessen their adhesion to each other, that they may be completely separated in every point. It is to effect this that the paper is prepared, by covering it with a size, which may be written on with facility, and on which the finest lines may be traced, without blotting the paper. Various means may be found of communicating this property to paper. The following preparation is always found to succeed, and

when the operation is performed with the necessary precautions, admits of the finest and most delicate lines being perfectly transferred, without leaving the faintest trace on the paper. For this purpose it is necessary to take a strong unsized paper, and to spread over it a size, prepared of the undermentioned materials :

	Drachms.
Starch	120
Gum Arabic	40
Alum	21

A moderately thick paste is made with the starch, by means of heat; into this paste is thrown the gum arabic and the alum, which have been previously dissolved in water, and in separate vessels. The whole is mixed well together; and it is applied warm to the sheets of paper by means of a brush, or a large flat hair pencil. The paper may be colored by adding to the size a decoction of French berries, in the proportion of ten drachms. After having dried this autographic paper, it is put into a press, to flatten the sheets; and they are made smooth by placing them, two at a time, on a stone, and passing them under the scraper of the lithographic press. If, on trying this paper, it is found to have a tendency to blot, this inconvenience may be remedied by rubbing it with finely powdered gum sandarach. We give below another receipt, which will be found equally useful; and which has the advantage of being applicable to thin paper, which has been sized. It requires only that the paper be of a firm texture.

	Drachms.
Gum tragacanth	4
German glue	4
Spanish white	8
Starch	4

The tragacanth is to be put into a large quantity of water, to dissolve, thirty-six hours before it is mixed with the other materials. The glue is to be melted over the fire in the usual manner. A paste is made with the starch; and after having, whilst warm, mixed these several ingredients, the Spanish white is to be added to them, and a layer of this sizing is to be spread over the paper, as already described: taking care to agitate the mixture with the brush, to the bottom of the vessel, that the Spanish white may be equally distributed throughout the liquid.

We must not omit to notice two autographic processes which facilitate and abridge this kind of work, when it is desired to copy a fac simile, or a drawing in lines. The first of these methods is to trace, with autographic ink, any subject whatever, on a transparent paper, which is free from grease and resin; like that which is known in commerce by the name of papier vegetal; and, to transfer it to stone, this paper is to be covered with a transparent size; this operation is very difficult to execute, and requires much address, in consequence of the great tendency which this paper has to cockle or wrinkle when it is wetted. Great facilities will be found from using tissue paper impregnated with a fine white varnish, and afterwards sized over. In the second process, transparent leaves, formed of geatin or fish glue, are employed; and the design is traced on them

with the dry-point, so as to make an incision; these traces are to be filled up with autographic ink, and thence transferred.

The German artists principally make use of various tints, which are added to the original black and white impression. This mode of printing has been rarely adopted in this country; but, when employed with judgment, is capable of producing very beautiful effects. We may illustrate this by reference to a chalk drawing done in the common manner: when finished, an impression of this drawing is thrown on a polished stone, and a transparent coating of a waxy substance laid over the impression thus transferred. In this state it is sent to the artist, who must scrape away this waxy coating wherever he wishes white lights to appear. To produce a good effect, in this way, requires some judgment; the lights must never be scraped out too broad, for the impressions will have a snowy appearance, which will be very disagreeable, the effect must rather be produced by small scratches close to one another, it being well borne in mind that half tints of white cannot be scraped out. Every line scraped will be positive light; but the effect of half tints must be produced by the fineness of the lines, and not by the more or less scraping of the waxy coating. In scraping, the artist must feel that he has actually removed the waxy coating, and that the tool has touched the face of the stone, if not, the intended light will not tell, and the scraping becomes useless. For imitating the rough touches of white chalk, it is a very good plan to jag (by striking with a knife) the edge of the tool used in scraping. With such a tool, a ruggedness will be given to the scraping, which could not be easily imitated in any other manner; but, unless they are scraped with art, these lights will have a heavy and mechanical look in the printing.

There is another method of executing the tint plates, which some persons prefer: it is as follows. After the printer has thrown off an impression of the drawing on a polished stone, instead of laying on a waxy mixture, the stone is sent to the artist, who lays on gum water over all those parts which are intended to be white; a margin of gum must also be added, and the rest is done by the printer.

Lithographic chalk should have the qualities of a good drawing crayon, it should be even in texture and carry a good point. It is, however, difficult to avoid making it too soft and greasy on the one hand, and too brittle on the other. For the chalk, as for the ink, more or less of the soap, wax, and tallow, may be used, as the extent of the burning may render necessary, and the remedies pointed out for defects of the ink will enable the operator to judge of what is wanting.

The following proportions are the best :

	Ounces.
Common soap	1½
Tallow	2
Virgin wax	2½
Shell-lac	1

The manipulation is similar to that for the ink. It is well, however, to throw in a little of the

wax just before the flame is extinguished. Less black must be mixed with the chalk than with the ink, its only use being to color the drawing, so that the artist may see the lines he traces.

When the whole is well mixed, it should be poured into a mould, and very strongly pressed to prevent any bubbles, which would make the texture irregular.

We may now furnish some useful information relative to the kind of stone to be employed in lithography. The country adjacent to that wherein lithography originated is abundantly provided with stones suited to this art. There are immense quarries of it, disposed in layers, along the Danube, in the country of Pappenheim, and in several other spots. The principal quarries worked are at a village called Solenhofen. Every one admitting the existence of a first cause, must believe that Providence, who destined to this age the invention of an art favorable to the progress of civilisation, had formed a considerable mass of stones ready prepared for the service of lithography. They are, in fact, found disposed in layers of one, two, three, or more inches in thickness, in such a manner that it is merely necessary to raise them from the quarries, and to cut them into convenient sizes, their thickness being equal throughout in each strata. Nature, who acknowledges neither privilege nor monopoly, has distributed the same benefit amongst other countries also, though in a way less striking. Lithographic stones are found in France, Italy, Prussia, Britain, Spain, and in the United States. Researches made with greater care would undoubtedly discover them in a great number of places. All the lithographers of Paris make use, almost exclusively, of the stones from Germany. The reason of this is, that the French quarries have been badly worked, either from want of funds or ignorance. The first masses which presented themselves on the superficial strata have been employed; these stones are full of hollows, veins, or other defects, though otherwise of a good quality, being harder than those of Solenhofen. Those of the first quality, from Germany, are preferred for designs in crayons; those found in commerce are not all equally good. The following are the properties which denote the goodness of a lithographic stone.

White stones are generally inferior to other kinds, being less durable. Those of a yellowish, or rather a grayish tint, are to be preferred on account of their durability, and because their grain is generally most equal. Those which are covered with points, or little whitish parts resembling vermicella, ought to be altogether rejected, especially when it is necessary to make delicate drawings in crayon; as the marblings or shades of different colors deceive the eye of the artist, and prevent his giving to his work that effect and harmony which it ought to have. The strata with stripes of a more transparent tint than the rest of the stone ought to be rejected, not only because they are liable to split, but because they take the ink more readily in those parts, and leave the traces of it more strongly upon the designs. Stones, however, are met with, which have fine lines, or threads of a brownish hue,

which do not present any impediments to the success of the artist.

Stones which are hard and homogeneous acquire a more equal surface, and are better adapted to the harmony of the tints; they give a greater number of impressions without clogging, and furnish proofs more clear and brilliant, whilst the contrary is the case with those which are softer; the durability of a stone may be ascertained by scratching it with the point of a knife. Those which are soft retain with more difficulty the traces of the design in the light touches; they clog more readily, and consequently afford a smaller number of impressions. The metallic pen cuts them easily, which produces a clogging, and prevents the ink from flowing. The grain of these stones is always coarse and unequal. Those which have holes, or those which are unequal in their grain or in their hardness, present the same inconvenience; they check the point of the pen when employed in imitating line engraving, and do not admit of the artist giving clearness and neatness to his work. The soft parts being also more easily acted on by the acid are corroded, and injure the parts of the design with which they have been covered. Stones which have any defect whatever, ought never to be used for the crayon, with which it is necessary to draw with particular care; they are therefore generally used for works in ink. The thickness of the stones is immaterial, provided they are not too thin; for in this case there is a risk of breaking them in the operation of printing. Their thickness ought to be proportioned to their surface; the smallest should not be less than an inch, when thicker they have the advantage of serving for a considerable number of designs; but they are very inconvenient when it is desired to remove or export them. It sometimes happens that a stone, the surface of which presents all the qualities which have just been spoken of, and which has succeeded well in the impressions of one or more copies, is found to be bad in the succeeding impressions.

The stones proper for lithography are composed of lime, argil, and silex. The first of these substances predominates, the third is found in very small quantity. A stone entirely calcareous does not answer for lithography, as has been proved by the marble of Carrara; the crayon and ink adhere to this stone with difficulty, and are readily effaced from it; the lines and the shades in a great measure disappear. One of the most certain indications of lithographical properties is the conchoidal fracture. All stones of this kind will be found good if they are also hard, and have all the fineness of grain and homogeneity of texture which are necessary.

The mode of *polishing* them must next be adverted to. Polishing is an operation by means of which a uniform and flat surface, and a polish more or less high, is given to the stone, according to the different kind of design or of work for which it is intended. The care and precision with which this first preparation of the stone is effected, are not of less importance to the execution of the design than to that of the impression. A stone, the grain of which is unsuitable for the

crayon, will not allow the artist to regulate his tints, and to give them harmony; when he works in ink, or with the dry point, he will meet with other obstacles if the polish of the stone be not perfect; and in each case his drawings will be defective; but they will be more so, if in the surface of the stone there are undulations, hollows, stripes, &c. Stones are polished with sand, by rubbing them one on the other. The best sand for this purpose is that quartzose sand which is fine and hard-grained. In Paris they in general make use of a yellow sand, which, though fine, requires to be sifted. It is necessary to be very careful that the sand which is used be not mixed with gravel or any sharp angular substance, which would form stripes on the stones, the hollows of which would not receive the printing-ink, and there would consequently be white marks on the impressions. This serious evil is avoided by sifting the sand before it is used, and by rubbing the upper stone slowly at the commencement of the operation, and occasionally turning it round upon the lower stone.

The kind of design for which a stone is intended determines the kind of polish which should be given to it. A work in which the crayon is used cannot be executed unless the stone have a grain left upon it; all other kinds of drawing require surfaces which have the polish of marble. Whether we wish to employ a fresh stone, or to renew one which has been already used, it must equally undergo the process of polishing. For this purpose it is placed on a table; a little sand is very equally sifted over it, which is moistened with a very little water. On the first stone is placed a second, as nearly as possible of the same dimensions, and the upper one is rubbed about in a direction nearly circular, but drawing it successively towards the four corners, and continually changing the relative position of the stones, so that every part of their surfaces may be subjected to an equal degree of friction. If this be neglected, and the stones be pressed on each other, and the circular motion be always the same, hollows will be formed, and uneven surfaces produced; and these irregularities will show themselves in the impressions. It is easy to ascertain, by means of a straight line, whether the stone be well levelled.

At first the motion should be slow, and the pressure trifling, the rapidity of the one and the force of the other increasing as the sand becomes equally distributed. When the sand becomes reduced to a paste, it no longer acts upon the stone; fresh sand must be taken until the stone be perfectly smooth, and there no longer remain on it the traces of any former design. The ink which formed this design may have been made to disappear without our having removed the source of its reproduction. This cause exists in the particles of the fatty substance of the crayon, or of the ink, which have penetrated below the surface of the stone, and which, being again brought in contact with the printing-ink, will retain it, and reproduce part of the old design. It may be known that this cause exists, when it is perceived that in the wet stone there are light traces of the former drawing. It is

then necessary to continue the rubbing until these have entirely disappeared. The aquafortis employed in the preparation of the stone for printing will, by itself, produce this effect when the traces are very superficial. It should be remarked, that, of two stones of the same size, the lower becomes polished sooner than the upper one. To avoid this it is only necessary to change their position.

In order to produce, on a stone intended for a drawing on crayon, the grain which it ought to have, it is necessary, after having treated it as we have just described, to sprinkle and rub it again with fine sand, which, by the friction it produces, may be made to give the desired grain. When it is wished to obtain a coarse grain, the stone is rubbed for a less space of time with the sand, this being also renewed more frequently; but the rubbing with the same sand is prolonged when a very fine surface is required. This rubbing, however, should not be continued too long, or the grain which has been produced will be destroyed. The state of the grain may be judged of by blowing briskly on the surface of the stone, on which has been placed a little water, and then examining its plane by looking at it in an oblique direction.

When stones intended for drawings in ink, or with other materials fit for lithography, are to have a very high polish given to them, the procedure is the same as that we have just described, excepting only, that, after having produced a fine grain on the surface, the rubbing is continued with the same sand reduced to a thin paste, taking care to wet the stones when the adhesion between them becomes so great as to prevent them moving freely. The workman, when he discontinues his labor, should not leave the stones in this state, as they would adhere, and could then be separated only by keeping them in a vessel full of water.

The stones, having acquired by the operation described a certain degree of polish, are well washed, in order to remove the grains of sand, which might produce scratches; a fine polish is then to be given to them by means of pumice-stone. This polishing is effected on one stone at a time, by rubbing it with a large piece of pumice-stone after it has been slightly moistened. The rubbing should be in a straight line, sometimes in one direction and sometimes in the opposite, passing successively over all parts of the surface of the stone. By this rubbing with the pumice-stone, and the white paste which it produces, only adding water enough to preserve a slight degree of moisture, the beautiful polish of marble is produced. It is afterwards necessary to wash the stone in a considerable quantity of water, rubbing it with the hand, or with a cloth entirely free from grease, and thus to remove any particles of matter, which, by their position on the surface of the stone, would present a substance intermediate between the surface and the drawing, which would prevent the adhesion of the latter.

Three kinds of grain may be given to stones, the coarse, the middling, and the fine. The first produces designs, the proofs of which have not the finish and delicacy of those which are ob-

tained on the two others. The second ought in every case to be preferred, for it possesses all the properties requisite for beauty of execution, although the proofs which it produces have not an appearance quite so soft and mellow as those from stones with the finest grain. But these last have the great disadvantage of soon losing the delicacy of the design, of clogging readily, and consequently of affording much fewer proofs. In every case it is necessary that the grain should be smooth and uniform over the whole surface of the stone, otherwise the lines traced by the crayon will be found nearer to each other, or more strongly marked in some places than in others; the proofs, in reproducing the same defects, will be found without harmony and without effect.

When it is intended to execute very beautiful designs, it is necessary to reject the stones which are too soft; those which have hollows; those whose texture is softer in particular spots than in the general mass; those which are not of equal thickness, and which have inequalities in their upper surfaces; those, in short, which are not of a good quality and well polished.

A last precaution, is, to preserve the grained or polished stones under cover, to protect them from the air and the dust, and not to touch them with the hand, or any greasy substance, on that side which is to be worked upon. They are preserved by wrapping them up carefully in an envelope of white paper. To prevent the stone being soiled by the hand, with which it is very likely to come in contact, Mr. Lullmandel, in his admirable work on Lithography, recommends the use of a rest, A B, fig. 2, which supports the hand, and is furnished with a slider K, which may be tightened by a screw *d*, at any required point. The smaller diagram represents the moveable rest taken from its place, with the supporting plane *i i*.

As, in graining the stone, a portion of dust will always remain on its surface, notwithstanding the washing previously performed by the workman, this dust existing between the chalk of the stone itself, will hinder many portions of the pencil from adhering properly, and thereby occasion some of the tints to be rotten. It is prudent, consequently, on the part of the draughtsman, either to wash the stone well in pure water, or to rub the face with a piece of clean flannel, and afterwards to brush off the dust: great care must be taken not to begin the drawing until the stone be perfectly dry. These directions refer solely to grained stones, polished stones requiring a mere wiping with a clean cloth or brush.

As it is very difficult to alter any part of a drawing, and it is almost always necessary to execute it reversed on the stone, in order that it might print the right way, it is requisite to have a correct outline. If any parts be made out on the stone with a lead pencil, it must be drawn with a very hard one, and the line must be extremely fine and delicate; otherwise, if a thick line be drawn, the portions of lead existing between the face of the stone and the chalk will hinder the latter from adhering, and a white line will appear where the lead pencil had been

applied. The best method to follow is this:—having made a correct outline of the subject on paper, take some French tracing paper (never use in any case oiled or varnished paper), and place a piece over the outline; as this paper is transparent, the whole drawing will be seen through. You may now trace an outline either with a soft lead pencil (if a chalk drawing is intended), or with red chalk (if an ink drawing). This outline, when completed, must be placed on the stone true and square, another thick piece of paper placed over the whole, and this latter piece well rubbed (without shifting) at the back, with a piece of ivory, or the handle of a knife, when the entire outline will be found to be transferred, reversed on the stone.

We have stated above that the outline on the French tracing-paper must be made with red chalk, if an ink drawing is the object; because black-lead, however soft, comes off with great difficulty on a polished stone, whereas red chalk comes off very easily.

The method given above is very convenient when the subjects are small; but, when they are above eight or nine inches in length, and accuracy is required, it is unsafe to follow it, because the paper extends by rubbing, and a double, or at least a thick and blurred outline, is the consequence. When the drawing is large, the tracing-paper must be placed over the original outline, and the lines drawn with a pen and Indian or common ink, and the upper face (of this tracing), or side on which the ink lies, be rubbed over with a piece of cotton and black lead, or red chalk; the overplus of the dust must then be well shaken off, and the face of the paper thus rubbed laid on the stone, so that the ink outline (which is clearly seen through) may be the reverse of the original; these lines must be carefully gone over with a blunt etching needle, when a pure outline will be found traced on the stone. As soon as the lines have all been gone over, the paper may be pulled up, and the face of the stone, being well brushed, is ready to be commenced upon with the drawing.

In order to copy the drawing, so that it may be reversed, the best method is to place the original drawing at the foot of, and before, a looking glass, and copy from the glass instead of consulting the drawing. In placing the drawing upon the stone, it is very important to recollect that a space or margin, of at least half an inch, and more if possible, must be left between the extremities of the drawing and the edge of the stone, and a still larger space left at the bottom than at the top of the drawing, in order to have room for the writing, if any is intended to be placed under the subject; for, unless this be attended to, the drawing cannot be printed, and the whole labor of the artist is lost. It happens, however, that some stones have small black veins, like hair lines, which run across them, as well as other little imperfections. The artist ought, therefore, always to take these defects (if existing) into consideration, when he puts his tracing on the stone; for often the drawing may be so placed that these black veins (which are apt to print) are lost in the dark tints of the foreground: or if there are detached and separate subjects on

the stone, he may place these so that the veins shall come between them, as in this case they are of little consequence: or else, if the stone is large enough to allow it, there is no absolute necessity to place the drawing in the middle; but it may be made on one side so as to avoid the veins, &c.

The drawing, being finished on the stone, is sent to the lithographic printer, on whose knowledge of his art the success of the impressions entirely depends. The first process is to etch the drawing, as it is called. This is done by placing the stone obliquely on one edge over a trough, and pouring over it very dilute nitric acid. It is poured on the upper part of the stone, and runs down all over the surface. The stone is then turned, and placed on the opposite edge, and the etching water, being collected from the trough, is again poured over it in the same manner. The degree of strength, which is little more than one per cent. of acid, should be such as to produce a very slight effervescence; after the etching water has lain on the stone for a second or two its strength must vary according to the heat of the atmosphere, and the degree of fineness of the drawing. It is desirable to pass the etching water two or three times over the darkest parts of the drawing, as they require more etching than the lighter tints. Some stones, also, and different chalks, require different degrees of strength of the acid, and experience alone can guide the lithographer in his practice upon this point. Chalk drawings require weaker acid than the ink ones.

The stone is now carefully washed by pouring clean rain-water over it, and afterwards with gum-water: and, when not too wet, the roller, charged with printing-ink, is rolled over it in both directions, sideways, and from top to bottom, till the drawing takes the ink. It is then well covered over with a solution of gum-arabic in water, of about the consistency of oil. This is allowed to dry, and preserves the drawing from any alteration, as the lines cannot spread, in consequence of the pores of the stone being filled with the gum. After the etching, it is desirable to leave the stone for a day, and best not to leave it more than a week, before it is printed from. In some establishments a few proofs are taken immediately after the drawing is etched, but it is better not to do so.

The operation of the etching requires great nicety, and must be done quickly. If the drawing is etched too strongly, the fine tints disappear; if too weakly, the printing-ink mixes with the darker parts, and the drawing runs into blots. A soft stone requires weaker acid than a hard one, if they are equally pure in quality. The differences in the compositions of the stones also require differences in the strength of the etching water, so that no strict rules can be given. The effect of the etching is, first, to take away the alkali mixed with the drawing chalk, or ink, which would make the drawing liable to be affected by the water; and, secondly, to make the stone refuse more decidedly to take any grease. The gum assists in this latter process, and is quite essential to the perfect preparation of the surface of the stone.

VOL. XIII.

An experiment has lately been made to take off impressions from plants by lithographic printing. A specimen of *Sibthorpia Europæa*, which was gathered several years ago in Cornwall, was covered with lithographic ink and impressed on a stone, from which stone several impressions were afterwards taken. The experiment was not so successful as was wished, but still promised to be beneficial in leading to the means of multiplying copies of the impressions of plants, much more accurate, in some respects, than a drawing can be expected to be.

The press formerly employed in the lithographic process, was exceedingly complicated; and, like the early German presses, but little adapted to the higher branches of the art. This cumbersome apparatus has now, however, been materially simplified by Messrs. Taylor and Martineau, to whom the public have been some time indebted for an improved typographical press. Messrs. Taylor and Martineau's press is faithfully represented in plate LITHOGRAPHY, fig. 1; and its arrangement may be best understood by reference to the various parts lettered in the engraving.

The cast iron uprights *aa* form the sides of the press, and are firmly attached to the base and table beneath. The carriage *b*, with its stone *c*, slide upon the rail-way *dd*, the former being supported by small rollers, which considerably diminish the friction that might otherwise arise from the weight of a large stone. A strong handle, *e*, is attached to the roller *f*, by means of which motion is given to the carriage. The scraper, *g*, is depressed by means of a spiral placed at the extremity of the handle, *h*; and, as the scraper is only in operation upon the narrow line with which it is immediately in contact, the entire force exerted upon every part of its surface is as great as in a press requiring more than several hundred times the power. *i* represents the tympan, and the regulating screw, *k*, is employed to adjust the press to the various stones that may be required in the different branches of this art.

The number of impressions which can be taken from a chalk drawing will vary according to the fineness of the tints. A fine drawing will give 400 or 500; a strong one from 1000 to 1500.

Ink drawings and writings give considerably more than copper-plates. The finest will give 6000 or 8000, and strong lines and writings many more. Upwards of 80,000 impressions have been taken at Munich from one writing of a form for regimental returns.

LITHOMANCY, LITHOMANTIA, in antiquity, a species of divination performed with stones. Sometimes the stone called siderites was used; this they washed in spring water in the night, by candle-light; the person that consulted it was to be purified from all manner of pollution, and to have his face covered: this done, he repeated certain prayers, and placed certain characters in an appointed order; and then the stone moved of itself, and in a soft gentle murmur, or in a voice like that of a child, returned an answer.

LITHOTRIPICK. See MEDICINE.

LITHOPHYTA, the name of Linnæus's third order of vermes. See ZOOLOGY.

LITHOSPERMUM, growell, a genus of F.

the monogynia order, and pentandria class of plants: cor. funnel-shaped, the throat perforated and naked: cal. quinquepartite. There are several species; but the only remarkable ones are these: 1. *L. arvense*, the bastard alkanet, grows in corn fields. 2. *L. officinale*, the common gromwell, grows in a dry gravelly soil. The seeds are reputed to be of service in calculous cases. Grew says that they have so much earth in their composition, that they effervesce with acids; but if this is the case it must be attributed rather to an alkaline than an earthy quality. Both are natives of Britain.

LITHOSTROTION, in natural history, a species of fossil coral, composed of a great number of long and slender columns, sometimes round, sometimes angular, jointed nicely to one another, and of a starry radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens.

LITHOSTROTON, among the Romans, was a pavement of Mosaic work, consisting of small pieces of cut marble of different kinds and colors. The lithostrota began to be used in the time of Sylla, who made one at Præneste in the temple of Fortune. At last they were used in private houses; and were brought to such perfection, that they exhibited most lively representations of nature, with all the exactness of painting.

LITHOTOMY. See **SURGERY**.

LITHUANIA is the former name of an extensive tract of country lying between Poland and Prussia (annexed to Poland in the fourteenth century), and now forming the three Russian governments of Wilna, Grodno, and Minsk. It was divided into two parts, called Samogitia and Lithuania Proper. Lithuania Proper was formerly divided into the palatinates of Troki and Wilna. It is flat and sandy, and intersected by vast marshes and bogs, and covered with immense pine, oak, and elm forests. Here bears, wolves, and wild boars, abound; and the urus, or wild ox, is sometimes found. Immense quantities of pot-ash and pearl-ash are annually produced from these woods; and honey is collected in great abundance. In some of the bogs is found an ochre which gives forty per cent. of tolerably good iron, copper, pyrites, petrifications, yellow amber, and the remains of marine animals. The pasturage is excellent in particular districts, and the cattle of a better breed than in Russia; and buck-wheat is raised in preference to any other. The Lithuanians are a sluggish race, and their appearance is generally very squalid. Their dress is a coarse shirt, covered by a woollen cloak or drawers, and sometimes merely a sheepskin. Their shoes are made of bark, and the harness of their horses of the more flexible branches of trees.

LITIGANT, *n. s. & adj.* } Lat. *litigo*, to
LITIGATE, *v. a. & v. n.* } strive; Fr. *litigans*,
LITIGATION, *n. s.* } *litigieux*. One en-
LITIGIOUS, *adj.* } gaged in a law suit:
LITIGIOUSLY, *adv.* } judicially contest-
LITIGIOUSNESS, *n. s.* } ing: to litigate is
to urge or manage a suit: litigious, disposed to

litigation in the legal or any other sense; also (obsolete) disputable; controvertible.

In *litigious* and controverted causes, the will of God is to have them to do whatsoever the sentence of judicial and final decision shall determine.

Hooker.

Soldiers find wars, and lawyers find out still
Litigious men, who quarrels move. Donne.

The cast *litigant* sits not down with one cross ver-
dict, but recommences his suit. Decay of Piety.

And by that we shall know who are the *litigants*
that like the two sons of Rebecca strive within us.

Jeremy Taylor.

Never one clergyman had experience of both *liti-
gations*, that hath not confessed, he had rather have
three suits in Westminster Hall, than one in the
arches. Clarendon.

No fences parted fields, nor marks, nor bounds,
Distinguished acres of *litigious* grounds.

Dryden's Georgics.

The *litigants* tear one another to pieces for the
benefit of some third interest. L'Estrange's Fables.

His great application to the law had not infected
his temper with any thing positive or *litigious*.

Addison.

The appellant, after the interposition of an ap-
peal, still *litigates* in the same cause.

Ayliffe's Parergon.

Judicial acts are those writings and matters which
relate to judicial proceedings, and are sped in open
court at the instance of one or both of the parties
litigant. Id.

Dar'st thou still *litigate* thy desp'rate cause,

Spite of these numerous, awful witnesses,

And doubt the deposition of the skies? Young.

LITMUS, or **LACMUS**, in the arts, a blue pig-
ment, formed from archil. It is brought from
Holland at a cheap rate; but may be prepared
by adding quicklime and spirit of urine to the
archil, previously bruised by grinding. The
mixture having cooled, and the fluid evaporated,
becomes a mass of the consistence of a paste,
which is laid on boards to dry in square lumps.
It is only used in miniature paintings, and can-
not be well depended on, because the least ap-
proach of acid changes it instantly from blue to
red. The best litmus is very apt to change and
fly. See **ARCHIL**, and **DYING**.

LITTER, *n. s. & v. a.* Fr. *litiere*. A sedan
or portable bed; the straw bed of animals or
plants; the brood or young of one litter or bed:
and (from beds of straw apparently) to strew
things carelessly about: any number of things
carelessly strewed.

To my *litter* strait;

Weakness possesseth me.

Shakspeare. King John.

To crouch in *litter* of your stable planks.

Shakspeare.

Then was this island,

Save for the son that she did *litter* here,

A freckled whelp, hag-born, not honoured with

A human shape. Id. Tempest.

I do here walk before thee like a sow that hath
overwhelmed all her *litter* but one. Shakspeare.

He was carried on a rich chariot *litter*-wise, with
two horses at each end. Bacon's New Atlantis.

The whelps of bears are, at first *littering*, without
all form or fashion. Hakewill on Providence.

The drowsy frightened steeds,

That draw the *litter* of close-curtained sleep.

Milton.

We might conceive that dogs were created blind,
because we observe they were *littered* so with us.

Browne.

He found a stall where oxen stood,
But for his ease well *littered* was the floor.

Dryden.

Here modest matrons in soft *litters* driven
In solemn pomp appear.

Id. Æneid.

Fruitful as the sow that carried
The thirty pigs at one large *litter* farrowed.

Id. Juvenal.

A wolf came to a sow, and very kindly offered to
take care of her *litter*.

L'Estrange.

Reflect upon that numerous *litter* of strange,
senseless opinions, that crawl about the world.

South.

Take off the *litter* from your kernel beds.

Evelyn.

Strephon, who found the room was void,
Stole in, and took a strict survey
Of all the *litter* as it lay.

Swift.

They found
The room with volumes *littered* round.

Id.

The *LITTER*, *lectica*, was carried upon shafts, and was anciently esteemed the most easy and elegant kind of carriage. Du Cange derives the word from the barbarous Latin *lecteria*, straw or bedding for beasts: others from *lectus*, a bed; there being ordinarily a quilt and a pillow to a *litter* in the same manner as to a bed. Pliny calls the *litter* the traveller's chamber: it was much in use among the Romans, among whom it was carried by slaves kept for that purpose; as it still continues to be in the east, where it is called a *palanquin*. The Roman *lectica*, made to be carried by four men, was called *tetraphorum*; that by six, *hexaphorum*; and that by eight, *octaphorum*. The invention of *litters*, according to Cicero, was owing to the kings of Bithynia: in the time of Tiberius they were become very frequent at Rome, as appears from Seneca; and even slaves were carried in them, though never by more than two persons.

LITTLE, *adj.*, *n. s.* & *adv.* } Sax. *lyeal*;
LITTELENSS, *n. s.* } Goth. *litill*, *litt*;

Swed. *lyt*, comparative *less*, superlative *least*, which see. Small in bulk, or extent of space or time; not much; not many; some: hence of small power, dignity, or importance: as a substantive, a small space, part, or affair: as an adverb, small in degree or quantity: *littleness* is smallness (of any kind); meanness.

Nyle thou ghit drynke watir, but use a *littl* wyn
for the stomak and for thin ofte fallynge ynfirmytees.
Wiclif. 1 Tymo. v.

The coast of Dan went out too *little* for them.

Joshua, xix.

When thou wast *little* in thine own sight, wast
thou not made the head of the tribes?

1 Sam. xv. 17.

A *little* sleep, a *little* slumber, a *little* folding of the
hands to sleep; so shall poverty come upon thee.

Proverbs.

And at the last a path of *littel* brede
I found, that gretly had not usid be,
For it forgrowin was with grass and wede,
That well unne this a wight might it se. *Chaucer.*
It is done by *little* and *little*, and with many es-
says; but all this dischargeth not the wonder.

Bacon's Natural History.

All trying, by a love of *littleness*,
To make abridgments, and to draw to less
Even that nothing which at first we were.

Donne.

Finding him *little* studious, she chose rather to en-
due him with conversative qualities of youth; as,
dancing and fencing.

Wotton.

If we find but a *little* pleasure in our life, we are
ready to dote upon it.

Bp. Hall's Contemplations.

All that is past ought to seem *little* to thee, be-
cause it is so in itself.

Taylor's Guide to Devotion.

He was a very *little* gentleman.

Clarendon.

And now in little space

The confines met.

Milton.

By sad experiment I know

How *little* weight my words with thee can find.

Id.

The poor sleep *little*.

Otway.

By freeing the precipitated matter from the rest by
filtration, and diligently grinding the white precipi-
tate with water, the mercury will *little* by *little* be
gathered into drops.

Boyle.

Much in *little* was writ; and all conveyed
With cautious care, for fear to be betrayed.

Dryden.

They have much of the poetry of Mæcenas, but
little of his liberality.

Id.

As if 'twere *little* from their town to chase,

I through the seas pursued their exiled race.

Id.

His son, being then very *little*, I considered only
as wax, to be moulded as one pleases.

Locke.

There are many expressions, which, carrying with
them no clear ideas, are like to remove but *little* of
my ignorance.

Id.

I leave him to reconcile these contradictions,
which may plentifully be found in him, by any one
who will but read with a *little* attention.

Id.

One would have all things *little*; hence has tried
Turkey poults, fresh from the egg, in batter fried.

King.

We may suppose a great many degrees of *littleness*
and lightness in these earthy particles, so as many
of them might float in the air.

Burnet.

The English and French, in verse, are forced to
raise their language with metaphors, by the pompous-
ness of the whole phrase, to wear off any *littleness* that
appears in the particular parts.

Addison.

I view with anger and disdain,

How *little* gives thee joy or pain:

A print, a bronze, a flower, a root.

Prior.

The angelick grandeur, by being concealed, doe
not awaken our poverty, nor mortify our *littleness* so
much, as if it was always displayed.

Collier.

Where there is too great a thinness in the fluids
subacid substances are proper, though they are
little astringent.

Arbuthnot.

These they are fitted for, and *little* else.

Cheyne.

A *little* learning is a dangerous thing;

Drink deep, or taste not the Pierian spring.

Pope.

Several clergymen, otherwise *little* fond of obscure
terms, yet in their sermons were very liberal of a
those which they find in ecclesiastical writers.

Swift.

The received definition of names should be change
as *little* as possible.

Watts's Logic.

As man was made for glory and for bliss,

All *littleness* is in approach to woe.

Young.

The great art of life is to play for much, and stak

Johnson.

little.

LITTLE (William), an ancient English his-
torian, called also Gulielmus Neuburgensi:
born at Bridlington in Yorkshire, in 1136; as

educated in the abbey of Newborough, where he became a monk. In his advanced years, he wrote a history of England, in five books, from the Norman conquest to A.D. 1197; which, for veracity, regularity of disposition, and purity of language, is one of the most valuable productions of that period.

LITTLETON (Adam), an eminent lexicographer, descended from an ancient family in Shropshire. He was born in 1627, educated at Westminster school, and went to Oxford, a student of Christ Church, whence he was ejected, by the parliament's visitors, in 1648. Soon after he became usher of Westminster school; and, in 1648, was made second master. After the Restoration he kept a school at Chelsea, of which church he was admitted rector in 1664. In 1670 he took his degrees in divinity, being then chaplain to Charles II. In 1674 he became prebendary of Westminster, of which he was afterwards subdean. Besides the well known Latin and English Dictionary, he published several other works. He died in 1694.

LITTLETON (Edward), LL.D., a learned English divine, educated at Cambridge in 1716. In 1729 he was elected fellow of Eton College, and presented to the living of Maple Derham, Oxford. In 1730 he took his degree, and was appointed chaplain to king George I. He died in 1734; and his discourses, in 2 vols. 8vo., were printed for the benefit of his family, under the patronage of queen Caroline. His celebrated poem on a spider, and other fugitive pieces, are preserved in Dodsley's Collection.

LITTLETON, or LYTTLETON (Sir Thomas), judge of the common pleas, was the eldest son of Thomas Westcote, esq., of Devonshire, by Elizabeth, sole heiress of Thomas Littleton of Frankley in Worcestershire, at whose request he took the name and arms of that family. He was educated at Oxford or Cambridge; and was afterwards, by Henry VI., made steward of the court of the palace. In 1455 he was appointed king's serjeant; and, in 1466, a judge of the common pleas, under Edward IV. In 1474 he was created knight of the Bath. He died in 1481; and was buried in the cathedral of Worcester, where a marble tomb, with his statue, was erected to his memory. He was author of the *Treatise upon Tenures*, on which Sir Edward Coke wrote a comment, well known by the title of *Coke upon Littleton*.

LITTORALE, an Italian word signifying the *sea coast*, applied particularly to the Hungarian province on the coast of the Adriatic, comprising the three towns Fiume, Buccari, and Porto-Re, with their territories, on the northern coast of Dalmatia. It formerly belonged to the military district of Croatia. The emperor Joseph II. annexed it to Hungary in 1776, and gave it a civil government for the encouragement of Hungarian commerce. The district had, in 1787, 19,928 inhabitants upon 140 square miles. From 1809 to 1814, it formed part of the Illyrian provinces of France. In 1814, it was restored to the Austrian empire, and, in 1822, was re-united with the provinces of the crown of Hungary. The seat of government is at Fiume.

LITURGY. Gr. *λειτουργία*; Fr. *liturgie*. Form of prayer; devotion. See below.

LITURGY is derived from *λειτουργ*, public, and *εργον*, work; and includes all the ceremonies belonging to public worship. In a more restrained signification, liturgy is used among the Romanists to signify the mass; and, in the church of England, the book of common prayer. All who have written on liturgies agree that, in the primitive days, divine service was exceedingly simple, clogged with very few ceremonies, and consisted of but a small number of prayers; but, by degrees, they increased the number of external ceremonies, and added new prayers. Liturgies have been different in different times and countries. There are liturgies of St. Chrysostom, St. Peter, St. James, St. Basil, of the Maronites, of the Coptæ; the Armenian, Roman, Gallican, Ambrosian, Spanish, African, and English liturgies, &c. In the early ages of the church, every bishop had a power to form a liturgy for his own diocese; and, if he kept to the analogy of faith and doctrine, all circumstances were left to his own discretion. Afterwards the whole province followed the metropolitan church, which became the general rule of the church; and this Lindwood acknowledges to be the common law of the church; intimating that the use of several services in the same province, which was the case in England, was not to be warranted but by long custom. The liturgy of the church of England was composed in 1547, and established in the second year of Edward VI. In his fifth year it was reviewed; because some things were contained in it which showed a compliance with the superstition of those times, and which were objected to by Calvin, and some learned men at home. Some alterations were made in it; the general confession and absolution were added; and the communion was made to begin with the ten commandments. The use of oil in confirmation, and extreme unction, were taken away; also prayers for souls departed. This liturgy, so reformed, was established by act of 5 and 6 Edward VI., cap. 1: abolished by queen Mary (who enacted that the service should stand as it was used in the last year of Henry VIII.); but re-established with a few alterations and additions, by 1 Eliz. cap. 2. Some farther alterations were introduced by order of king James I., in the first year of his reign; particularly in the office of private baptism, in several rubrics, &c.; with the addition of five or six new prayers and thanksgivings, and all that part of the catechism which contains the doctrine of the sacraments. The book of common prayer, thus altered, remained in force from the first year of king James I. to the fourteenth of Charles II. The last review of the liturgy was in 1661; and the last act of uniformity, enjoining the observance of it, is 13 and 14 Car. II., cap. 4. Many applications have been since made for a review, but hitherto without success.

LITUUS, among the Romans, was the staff made use of by the augurs in quatering the heavens. It bore a great resemblance to the crozier of a bishop, but was shorter. It was crooked at one end, and thickest in the curved part, according to A. Gellius. We frequently

meet with a representation of it upon medals, amongst other pontifical instruments. It was called *Lituus Quirinalis*, from *Quirinus*, a name of *Romulus*, who was skilled in all the mysteries of augury.

LITÆUS was also an instrument of music in use in the Roman army. It was straight, excepting that it had a little bending at the upper end like the *lituus* or sacred staff of the augurs; and from the similitude it derived its name. The *lituus*, as an instrument of martial music, was of a middle kind betwixt the cornu and the tuba.

LIVADIA, a province of European Turkey, the ancient *Achaia* and *Hellas*, or Greek Proper; bounded on the north by *Epirus* and *Thessaly*, from which it is separated by *Mount Oeta*, now *Banina*, and by the *Euripus*, now the strait of *Negropont*; on the east by the *Archipelago*; on the south by the gulf of *Engia*, the isthmus of *Corinth*, and the gulf of *Lepanto*; and on the west by the *Ionian Sea* and part of *Epirus*. Its extent is about 180 miles from north-west to south-east: its greatest breadth not above forty. It is in general mountainous, but pleasant and fruitful. The principal mountains are, the *Oeta* in *Bœotia*, where is the famous pass of *Thermopylæ*, not above twenty-five feet broad; and *Parnassus*, *Helicon*, and *Cytheron* in *Phocis*, celebrated by the poets. The rivers of most note are, the *Sionapro*, the ancient *Achelous*, the *Cephisus*, the *Ismenus*, and the *Asopus*. The province is at present divided into *Livadia Proper*, *Stramulippa*, and the duchy of *Athens*. The principal places are, *Lepanto*, anciently *Naupactus*; *Livadia*, anciently *Lebadia*; *Athens*, or *Setines*; *Thebes*, or *Stibes*: *Lepsina*, anciently *Eleusis*; *Castri*, formerly *Delphi*; and *Megara*. See *GREECE*.

LIVADIA, the capital of the above province, is a large and populous place, seated on the gulf of *Lepanto*, about fifty miles from *Athens*. It has a considerable trade in woollen stuffs and rice. Near this place is the cave of *Trophonius*. It contains about 10,000 inhabitants.

LIVE, *v. n. & adj.* } Sax. *līpan*; Swed. *lefva*; Goth. *liva*; Dan. *leve*; Belg. *leven*. To exist; be in animal existence; vegetate: hence to continue in life; pass life; converse, or cohabit (taking with); feed; live in happiness; remain undestroyed or unextinguished; be exempt from death: live, as an adjective, is quick; active: hence burning: livelless written by *Shakspeare* for lifeless: livelihood, means of living, a corruption of *livelode*, or lead, i.e. the manner of leading life. See *LODE*. *Livelong* is tedious; long in passage; lasting: lively, according to, or representing, life; active; strong; energetic; brisk; gay: briskly; vigorously; with near resemblance to life: liver, one who exists, or who lives in some particular manner: living, as an adjective, is synonymous with lively; as a substantive it signifies power or means of continuing life; main-

tenance; benefice of a clergyman; all who live: livingly in the state of the living.

In him was *lyf*, and the *lyf* was the light of men. *Wiclif. Jun. i.*

If one man's ox hurt another that he die, they shall sell the *live ox*, and divide the money. *Exodus.*

My statutes and judgments, if a man do, he shall live in them. *Lev. xviii. 5.*

The *living* know that they shall die. *Eccles.*

All they did cast in of their abundance; but she of her want did cast in all that she had, even all her *living*. *Mark.*

They which minister about holy things, *live* of the things of the temple. *1 Cor. ix. 13*

Tell me, madame, I you beseech

For sith the first of my *living*

Was I so fereful of nothing

As I am now to here you speke. *Chaucer's Dreame.*

By whiche the lesse whyle I looke to lyue with you, the more depeyle am I moued to care in what case I leaue you, for such as I leaue you, suche bee my children lyke to fynde you. *Sir G. Moore.*

His weary foe into that *living* well,

Gan high aduance his broad discoloured brest

Above his wonted pitch, with countenance fell,

And clapt his yron wings, as victor he did dwell. *Spenser. Fæerie Queene.*

A most notorious thief; *lived* all his life-time of spoils and robberies. *Spenser.*

If any loose *liver* have any goods of his own, the sheriff is to seize thereupon. *Id. on Ireland.*

Some of our ministers having the *livings* of the country offered unto them, without pains, will, neither for any love of God, nor for all the good they may do, by winning souls to God, be drawn forth from their warm nests. *Spenser.*

She gave like blessing to each creature,

As well of worldly *livelode* as of live,

That there might be no difference nor strife. *Hubberd.*

For ourselves we may a *living* make. *Id.*

My life thou shalt command, but not my shame: The one my duty owes; but my fair name, Despite of death, that *lives* upon my grave, To dark dishonour's use thou shalt not have *Shakspeare.*

Our high-placed *Macbeth*

Shall *live* the lease of nature, and pay his breath To time and mortal custom. *Id.*

The shepherd swains shall dance and sing,

For they delight each May morning.

If these delights thy mind may move,

Then *live* with me and be my love. *Id.*

The obscured bird clamoured the *livelong* night. *Id.*

Then may I set the world on wheels, when she can spin for her *living*. *Id.*

Is't night's predominance, or the day's shame, That darkness does the face of earth entomb,

When *living* day should kiss it? *Id. Macbeth.*

Men's evil manners *live* in brass, their virtues

We write in water. *Id. Henry VIII.*

Description cannot suit itself in words,

To demonstrate the life of such a battle,

In life so *liveless* as it shews itself. *Id. Henry V.*

Living creatures have voluntary motion, which plants have not. *Bacon's Natural History.*

Dr. Parker, in his sermon before them, touched them so near for their *living*, that they went near to touch him for his life. *Hayward.*

They brought their men to the slough, who discharging *lively* almost close to the face of the enemy, did much amaze them *Id.*

So short is life, that every peasant strives,
In a farm-house or field, to have three *lives*.

Donna.

None but our last enemy comes once for all ; and
I know not, if that : for even in *living* we die daily.

Bp. Hall's Contemplations.

The end of his descent was to gather a church of
holy christian *livers* over the whole world.

Hammond's Fundamentals.

The faithful minister *lives* sermons. *Fuller.*

Isaac and his wife, now dig for your life,

Or shortly you'll dig for your *living*. *Denham.*

That rebellion drove the lady from thence, to find
a *livelihood* out of her own estate. *Clarendon.*

Young and old come forth to play

On a sun-shine holiday,

'Till the *living* day-light fail. *Milton.*

But wherefore comes old Manoa in such haste,
With youthful steps ? much *livelier* than ere while
He seems ; supposing here to find his son,
Or of him bringing to us some glad news ? *Id.*

Now three and thirty rolling years are fled

Since I began, nor yet begin to *live*. *Browne.*

In vain do they scruple to approach the dead, who
livingly are cadaverous, or fear any outward pollution,
whose temper pollutes themselves.

Id. Vulgar Errors.

The Arcadians fought as in an unknown place,
having no succour but in their hands ; the Helots, as
in their own place, fighting for their *livings*, wives,
and children. *Sidney.*

Some so like to thorns and nettles *live*

That none for them can, when they perish, grieve.
Waller.

A louder sound was produced by the impetuous
eruptions of the halituous flames of the saltpetre upon
casting of a *live* coal upon it. *Boyle.*

The rays of wit gild wheresoe'er they strike,

But are not, therefore, fit for all alike ;

They charm the *lively*, but the grave offend,

And raise a foe as often as a friend ;

Like the resistless beams of blazing light,

That cheer the strong and pain the weakly sight.

Stillingfleet.

The number of soldiers can never be great in pro-
portion to that of people, no more than of those that
are idle in a country, to that of those who *live* by la-
bour. *Temple.*

Pity and he are one ;

So merciful a king did never *live*,

Loth to revenge, and easy to forgive. *Dryden.*

To save the *living*, and revenge the dead,

Against one warrior's arms all Troy they led. *Id.*

Mark how the shifting winds from west arise,

And what collected night involves the skies !

Nor can our shaken vessels *live* at sea,

Much less against the tempest force their way. *Id.*

In a spacious cave of *living* stone,

The tyrant Æolus, from his airy throne,

With power imperial curbs the struggling winds.

Id.

Pure oil and incense on the fire they throw ;

These gifts the greedy flames to dust devour,

Then on the *living* coals red wine they pour. *Id.*

That *liveliness* which the freedom of the pencil
makes appear, may seem the *living* hand of nature.

Id. Dufresnoy.

Since a true knowledge of nature gives us pleasure,
a *lively* imitation of it in poetry, or painting, must
produce a much greater. *Id.*

That part of poetry must needs be best, which
describes most *lively* our actions and passions, our
virtues and our vices. *Dryden.*

There is no *living* without trusting some body or
other, in some cases. *L'Estrange.*

He brings disgrace upon his character, to submit
to the picking up of a *livelihood* in that strolling way
of canting and begging. *Id.*

Extravagant young fellows, that have *liveliness* and
spirit, come sometimes to be set right, and so make
able and great men ; but tame and low spirits very
seldom attain to any thing. *Locke.*

The way to *live* long must be, to use our bodies so
as is most agreeable to the rules of temperance.

Ray on the Creation.

It was a miraculous providence that could make a
vessel, so ill-manned, *live* upon sea ; that kept it from
being dashed against the hills, or overwhelmed in the
depths. *Burnet.*

It is their profession and *livelihood* to get their *liv-*
ing by practices for which they deserve to forfeit their
lives. *South.*

His faith must be not only *living*, but *lively* too ;
it must be brightened and stirred up by a particular
exercise of those virtues specifically requisite to a due
performance of this duty. *Id.*

Most of the trades, professions, and ways of *living*
among mankind, take their original either from the
love of pleasure, or the fear of want. *Addison.*

When men of rank and figure pass away their *lives*
in criminal pursuits and practices, they render them-
selves more vile and despicable than any innocent
man can be, whatever low station his fortune and
birth have placed him in. *Id.*

If we are firmly resolved to *live* up to the dictates
of reason, without any regard to wealth and reputa-
tion, we may go through life with steadiness and
pleasure. *Id.*

They have been as often banished out of most other
places ; which must very much disperse a people, and
oblige them to seek a *livelihood* where they can find it.

Id. Spectator.

Be thy affections undisturbed and clear,

Guided to what may great or good appear,

And try if life be worth the *liver's* care. *Prior.*

The colours of the prism are manifestly more full,
intense, and *lively*, than those of natural bodies.

Newton's Opticks.

Imprint upon their minds, by proper arguments
and reflections, a *lively* persuasion of the certainty of
a future state. *Atterbury.*

Here are the wants of children, of distracted per-
sons, of sturdy wandering beggars and loose disor-
derly *livers*, at one view represented. *Id.*

A late prelate, of a remarkable zeal for the church,
were religions to be tried by *lives*, would have *lived*
down the pope, and the whole consistory. *Id.*

Those animals that *live* upon other animals have
their flesh more alkaliescent than those that *live* upon
vegetables. *Arbuthnot.*

The parson of the parish preaching against adul-
tery, Mrs. Bull told her husband that they would
join to have him turned out of his *living* for using
personal reflections. *Id.*

The tomb with manly arms and trophies grace

There high in air, memorial of my name,

Fix the smooth oar, and bid me *live* to fame.

Pope

Formed by thy converse, happily to steer

From grave to gay from *lively* to severe. *Id.*

How could she sit the *livelong* day,

Yet never ask us once to play ? *Swift.*

Sounds which address the ear are lost and won
In one short hour ; but that which strikes the eye
Lives long upon the mind ; the faithful sight
Engraves the knowledge with a beam of light.

Watts.

Live while you *live*, the Epicure would say
And snatch the pleasures of the present day ;

LIVERPOOL.

Live while you *live*, the sacred preacher cries,
And give to God each moment as it flies :
Lord, in my views let both united be,
I *live* to pleasure when I *live* to thee. *Doddridge.*
We are of Christ ; our concern is, to honour that
superior denomination, by *living* up to it. *Mason.*
When Love Divine, with brooding wings unfurled,
Called from the rude abyss the *living* world.

Darwin.

They only have *lived* long who have *lived* virtuously.
Sheridan.

She was not violently *lively*, but
Stole on your spirits like a May-day breaking ;
Her eyes were not too sparkling, yet, half-shut,
They put beholders in a tender taking. *Byron.*

LIV'ER, *n. s.* } Sax. *lifer* ; Swed. *lefver* ;
LIVERGROWN. } Dan. *lever* ; Teut. *liber*, à *li-*
ven, to live.—*Minsheu.* One of the most im-
portant of the entrails, of a dark red color : liver-
grown is having too great a liver.

And the caul above the *liver*—it shall he take
away. *Lev. iii. 4.*

With mirth and laughter let old wrinkles come ;
And let my *liver* rather heat with wine,
Than my heart cool with mortifying groans.

Shakspeare.

I enquired what other casualties were most like the
rickets, and found that *livergrown* was nearest.

Graunt.

The uppermost stratum is of gravel ; then clay of
various colours, purple, blue, red, *liver* colour.

Woodward.

LIVER, in anatomy. See ANATOMY, Index.
Plato, and others of the ancients, fix the prin-
ciple of love in the liver ; whence the Latin
proverb, Cogit amare jecur : and in this sense
Horace frequently uses the word, as when he
says, Si torrens jecur queris idoneum. The
Greeks, from its concave figure, called it *ηπαρ*,
vaulted or suspended ; the Latins, jecur, *q. d.*
juxta cor, as being near the heart. The French
call it foye, from foyer, focus, a fire-place ;
agreeably to the doctrine of the ancients, who
believed the blood to be boiled and prepared in
it. Erasistratus, at first, called it parenchyma,
i. e. effusion or mass of blood ; and Hippocrates,
by way of eminence, frequently calls it the hy-
pochondrium.

LIVERPOOL, a borough and corporate town,
and the second port in Great Britain, is in 53°
24' 40" of N. lat., and 2° 58' 25" W. long., cal-
culated from St. Paul's church in Liverpool. It
is situate in the county of Lancaster, and on the
river Mersey ; and although it is not easy of en-
trance, on account of sand-banks at the mouth of
the Mersey, it is the most accessible port of the
west coast of England.

Liverpool was first noticed for its trade with
Ireland. Leland, who wrote in the reign of Henry
VIII., says of Liverpool, that 'Irish merchants
cum much thither as to a good haven ;' and
Camden, in his Britannia published in 1586,
says, 'the Mersey spreading, and presently con-
tracting its stream from Warrington, falls into the
ocean with a wide channel, very convenient for
trade, where opens to view Litherpoole com-
monly called Lirpoolle, from a water extending
like a pool, according to the common opinion,
where is the most convenient and most frequented
passage to Ireland.' At an early period, too

the conveniency of the port of Liverpool as a
passage to the Isle of Man was sufficiently esti-
mated by the Stanley family ; and the trade to
Ireland and the Isle of Man, which commenced
at so early a period, has never been lost, but has
increased with their increasing wealth. Liver-
pool enjoys also a great coasting trade with
Wales, Bristol, London, the English maritime
corn counties, and with Scotland and Cumber-
land. In 1752 Liverpool employed only 122
vessels in the coasting trade : in 1818 2960
vessels were entered outwards as coasters at the
Liverpool custom-house : in 1823 3580 vessels
were reported inwards as coasters. Since which
time the coasting trade of Liverpool has prodig-
iously increased by the number of steam vessels
constantly employed in it.

As to the inland trade, the manufacturing towns
of Manchester, Bolton, Blackburn, Wigan, Pres-
ton, Rochdale, Oldham, Ashton-Underlyne,
Stockpool, Macclesfield, and Congleton, are all
within fifty miles of Liverpool, and have almost
all communication with it by water. By water
conveyance too the more distant towns of Hud-
dersfield, Halifax, and Leeds, have constant com-
mercial intercourse with Liverpool. 'A rapid
communication also subsists between Liverpool,
Birmingham and Sheffield ; and great quantities
of hardware and polished goods, the manufactures
of these towns, are in the constant course of
transit to Liverpool. At the distance of about
fifteen to twenty miles from Liverpool is an inex-
haustible supply of excellent coal, which is
brought down by canal. The river Weaver,
which is navigable from Northwich to the Mer-
sey, furnishes an easy conveyance to Liverpool
for the produce of the salt works of Northwich
and Winsford. Liverpool has communication
by water with Staffordshire, and draws from that
county immense stores of iron and earthenware.
At St. Helen's and Warrington, the former within
twelve and the latter nineteen miles from Liver-
pool, are most extensive manufactures for plate
glass and glass bottles. The amount of the com-
mercial dealings between Liverpool and the in-
land district is beyond all computation. By a
railway, now laying down between Liverpool and
Manchester, the communication with the large
manufactures will be more direct and facile, and
an increase of traffic will necessary result from it.

In respect to its foreign trade, Liverpool is the
peculiar port for vessels belonging to the United
States ; and, by lines of packet ships sailing be-
tween Liverpool and several of the principal
ports in the United States on stated days and
with the utmost punctuality, the most rapid
communication is kept up between the two coun-
tries. Most of the timber vessels from North
America import their cargoes into Liverpool.
The commerce of Liverpool with the infant States
of South America is also immense ; and since
the opening of the East India trade Liver-
pool has entered spiritedly into it, and now
maintains a regular and advantageous commerce
with it. Regular trading vessels are also estab-
lished between Liverpool and New South Wales.
In the West India trade Liverpool has now far
outstripped Bristol. It has still some trade with
Africa ; but no longer of the degrading and dis-

gusting character for which it was once so memorable. It has considerable trade too with Russia and all the European ports; in short

Liverpool participates in all foreign unmonopolized commerce, except the Greenland trade, which it has abandoned for the last few years.

Importation into London of grain, &c., from the 1st of January to the 1st of December 1827.						Importation into Liverpool during the same period.

A statement is annually made by the Liverpool timber brokers of the quantity of timber imported into Liverpool during the preceding year. Their calculation is to each 1st of February, and the following is the table of imports from the 1st of February 1826 to the 1st of February 1827.

Pine (British America), cubic feet	4,168,000
Quebec deals, standard	1569
Quebec oak, cubic feet	290,400
Quebec elm and ash	92,000
Quebec staves	668
Pine planks	2,200,000
Hardwood, cubic feet	290,000
Lathwood, fathom	1,529
Timber, Dantzic, Munich and Stettin, cubic feet	764,000
— Riga (Baltic)	51,000
Deals, standard	3400
Wainscot logs { whole	610
{ half	162
Deck planks, pieces	5200
Staves pipe, M	42
Lathwood, fathom	640
Cedar Havannah logs	1888
Pencil cubic feet	3000
Pitch pine	26,700
African oak	124,000

The tides of the Mersey vary from twenty to thirty feet in spring tides, and from ten to fifteen feet at neap tides. Vessels exceeding 800 tons in burthen have come into the port at the height of spring tides; but the Liverpool merchants seldom build vessels of greater burthen than 400 to 500 tons, from the danger of their being neaped, and on account of the delay which always attends the loading and unloading of large vessels.

Few maritime towns possess accommodations for ships at all comparable to Liverpool; for it has now six docks, viz. the Dry dock, the Salt-

house dock, the King's dock, the Queen's dock, the George's dock, and the Prince's dock, which with their basins occupy about forty-five acres of land. These docks communicate with the river, and vessels have an easy entrance into them from it, at flood tide. The old dock, which was made early in the last century, was closed at the beginning of the present year (1827), an arrangement having taken place between the government and the corporation of Liverpool for the erection on its site of a custom-house and other government buildings. But the present dock-room, extensive as it is, is insufficient for the commerce of the port, and a large dock to the northward is now constructing, and another to the southward will be commenced in the course of next year: by which the extent of dock-room will be increased to seventy-five acres. Steam vessels have greatly increased in number during the last four years, and a dock for their accommodation exclusively is now in rapid progress. Communicating with the present docks are several graving docks, as they are called, where vessels undergo repair. They are taken in at tide time and the gates are then closed, and the water is let out by flood-gates as the tide ebbs; the tide is afterwards wholly excluded, so that vessels in these docks can be thoroughly examined from the keel upwards. The docks are vested by act of parliament in trustees consisting of some members of the Liverpool corporation, and some merchants not of the corporation. Perhaps in the abstract it is objectionable that members of the corporation should be dock trustees also, as there is occasionally a collision of interest between the corporation and dock estates: whether the system has been practically mischievous or not we will not stop to enquire. At present the dock trustees are vigilantly watched by the public, and they seem to have set on foot a judicious system

for the management of their large revenue. The dock duties, for the year ending June 1827, amounted to £145,000.

Besides the docks above enumerated the trustees of the duke of Bridgewater, and the Manchester old quay company, have docks at Liverpool for the convenience of the flats and barges plying on their respective navigations. And, for the examination and repair of vessels, a patent slip has lately been erected by a private individual at Wallasey Pool on the Cheshire side of the Mersey. The advantage of the patent slip over graving docks is said to be that it is made at a comparatively trifling expense, and that vessels can be better examined there, as no part of the day light is kept from the bottoms of the vessels, whilst in graving docks a great deal of light is obstructed by the sides of the graving docks, which are narrow, and which could not be made wider on account of the necessity of shoring up vessels previous to repair.

A telegraphic communication between Liverpool and Holyhead, by means of stations at intervals along the coast of North Wales has just been effected by lieutenant Watson, R. N., and is now in operation. Its objects are to give instant tidings of the arrival of ships off Holyhead, the variations of the wind there, and damage to shipping on the Welsh coast.

The limits of the parish and town are co-extensive, containing 2300 yards from east to west, and 4420 yards from north to south, and 10,400 yards in circumference, forming an area of 2202 acres, nearly one-half of which belongs to the corporation of Liverpool, and the rest to private individuals.

Liverpool sends two members to parliament: it is a corporation by charter, with a common council consisting of forty-one persons, from among whom a mayor and two bailiffs are annually chosen by the burgesses on St. Luke's day. Towards the end of the last century many trials at law were had between the burgesses and the common council, upon the construction of the charter, i.e. as to the power of the common council to make by-laws without the sanction of the burgesses in common hall, and as to their power to fill up vacancies occurring in the council. But these trials, though in favor of the burgesses, did not effect any alteration in the system; and so long as the council shall consist, as it now does, of gentlemen of intelligence, wealth, and integrity, and the revenue of the corporation estate shall be expended in improving and embellishing the town, and publicity be given to their proceedings in council, no other mode of election of common council-men would be more beneficial to the town. The income of the corporation estate, for the year ending October 1827, amounted to £88,980. There is a court for the trial of civil causes arising within the borough, at which the mayor and bailiffs and recorder preside; but the process of attachment against the goods of a debtor does not prevail here as in London and Bristol.

The population of Liverpool has increased since the commencement of the last century, at the following prodigious ratio:—

In 1700 it was	5145
1750 .	18,400
1801 .	77,653
1811 .	94,376
1821 .	118,972

But the census of 1821 does not contain the population of Harrington, Edgehill, Lowhill, Everton, and Kirkdale, townships immediately contiguous to it, and which are chiefly inhabited by persons having some daily pursuit in Liverpool. These contained, in 1821, 22,515 persons; and to them should be added almost 9000 sea-faring men belonging to the port, and of whom no return is made. These would form an aggregate of 150,000 persons, as the population of Liverpool and its suburbs in 1821; and the population has increased since that census.

In ship-building and repairing, in cordage and sail-making, a great many hands are employed. Here are also extensive brass and iron foundries; at the latter of which boilers, and all the necessary apparatus for steam vessels, are executed. Brewing, distilling, soap-boiling, and sugar-refining, are also carried on to a great extent. There are a great many windmills and steam corn-mills in the town and neighbourhood of Liverpool, and much corn is ground previous to its being sent into the manufacturing districts. The windmills are now generally upon a new construction, the principle of which is that by the action of a fan or pilot-sail, which varies with any change of wind, the mill-sails are always presented to the wind, and much watching, manual labor, and delay, are saved by it. Mordant and alkali, and other chemical works, connected with bleaching and dyeing, are increasing here rapidly. Tanning is carried on to considerable extent in Liverpool and the neighbourhood, but the interruption of commercial intercourse between this country and Buenos Ayres, in which Liverpool is most materially interested, fetters the operations of the Liverpool tanners. A steam-mill, on a very ingenious construction, for the separation of rice from the husk (or paddy, as it is called), has recently been erected in Liverpool. There is an immense bed of good clay in Liverpool, and great quantities of bricks are annually made here both for home consumption and for shipment abroad. They are all made by hand.

Liverpool can boast of many specimens of architectural taste. The town-hall and the exchange buildings probably rank first. The lyceum, the Wellington rooms, the infirmary, and the corn exchange, are beautiful structures, though certainly they are of different degrees of merit. The Saint John's market, which was erected by the corporation about five years ago, under the direction of their architect Mr. John Foster, jun., at an expense of £35,000, deserves a more detailed notice had we space for it. It is under excellent regulations, and the rents vary from £18 a year, (which is the price for the best shops), to 12s. a year, the rent for a bench compartment. Another roofed market on a similar plan, but smaller scale, has been erected near St. James's Church, from which it takes the name

of St. James's Market, and another is intended to be erected to the north of the town.

There are about twenty churches in Liverpool belonging to the establishment. These in general do not display much architectural beauty; but the church attached to the school for the blind, St. George's, St. Michael's and Christ's Church, are exceptions; and St. Luke's Church, at the top of Bold Street as a specimen of pure Gothic, when finished, will be scarcely exceeded in the kingdom. It is built by the corporation, from designs of their architect Mr. John Foster. The chapels belonging to the various denominations of dissenters greatly exceed in number the churches belonging to the establishment. There are five Roman Catholic chapels, a meeting-house for Quakers, and a Jews' synagogue. The churches and all the dissenting chapels have schools attached to them, and great facilities are afforded for the education of the children of the poor.

The charitable institutions are too numerous to detail. We shall content ourselves with naming the schools for the instruction of the indigent blind in music and several useful manufactures. It was established in 1791, and has perhaps never been surpassed for benevolence of design, and success as a charity. It is the parent of the London and other similar establishments.

A public cemetery, originating with the dissenters, was made a few years ago in Brunswick Road, by the contributions of share-holders. The building has a handsome stone front, the ground is well laid out; and the arrangements being such as to insure decent interment, and to prevent exhumation; and it has become a common repository for the dead. A cemetery, attached to the establishment, now constructing in the form of catacombs, on a very large scale at the Stone Delf, at the back of the St. James's Walk, is now rendered interesting by a monument to Mr. Huskinson, raised at the public expense.

Liverpool is deficient in public promenades, having only the St. James's walk and the marine parade, near the prince's dock: the latter, however, is beautiful, being of the extent of 700 yards along the side of the Mersey.

The Athenæum is an institution combining commercial and political information with literature, as it possesses a news-room and a most valuable library. The lyceum is a similar institution, but the books in the latter circulate amongst the proprietors.

The botanic garden, under the skill of its curator Mr. John Sheppard, has acquired both in England and abroad considerable reputation for its rare and valuable collection of native and foreign plants. The royal institution, which was opened in November 1817, has a charter of incorporation, and its object is the promotion of literature, science, and the arts, by academical schools, public lectures, the encouragement of societies, which may associate for similar objects; the collection of books, specimens of art, natural history, &c.; by promoting a laboratory and philosophical apparatus; and by associations of the proprietors. The new Zoological Gardens are likely to possess a great variety of specimens,

from the facility which foreign intercourse affords to Liverpool.

In the year 1826 an important undertaking was commenced by the spirited merchants of this commercial town, namely, a rail-road communication from Liverpool to Manchester, a distance of thirty-one miles. The object of this costly work is not merely the conveyance of passengers, but the transfer of goods of every description, such as had previously been transported by canal or by waggon. The expense of completing the entire line, including sixty-three bridges, and the road across Chat Moss, which in itself was an undertaking of the most expensive kind, exceeded one million sterling; and the interesting ceremony of opening the railway took place on the 15th of September, 1830, in presence of the duke of Wellington, and many of the nobility and gentry of the adjoining counties. The rejoicings and congratulations of this memorable day are clouded by the recollection of a melancholy event, the death of Mr. Huskinson, the representative of Liverpool, who was crushed beneath the wheels of one of the locomotive engines, and died shortly after. The quantity of goods now annually conveyed by this mode of transport amounts to 40,000 tons, and of coals an equal weight. The number of passengers carried during the first two years after its construction, exceeded 200,000, but as many of those visited rather from curiosity than business, a diminution in the number may be reasonably expected.

LIVER-WORT, in botany. See LICHIN and MARCHANTIA.

LIVERY, *n. s.* } Fr. *livrer, livrée*; Ital. LIVERMAN, } Span. and Port. *lerrea, librea*, ex Lat. *libero*. A giving or taking legal possession; return from wardship; food, or clothes, given to servants, or followers, or at a certain rate; hence any particular or characteristic dress: liveryman, a footman; also in London, a freeman of a particular rank in some company.

I think it is our way,
If we will keep in favour with the king,
To be her men and wear her livery. *Shakespeare.*

On others Interest her gay livery flings,
Interest that waves on party-coloured wings;
Turned to the sun she casts a thousand dyes:
And as she turns the colours fall or rise. *Dunciad.*

Because no livery of seisin is necessary to a lease for years, such lease is not said to be seized, or to have true legal seisin of the lands. *Tomlin.*

My mind for weeds your virtue's livery wears. *Sidney.*

The witnesses made oath, that they had heard some of the liverymen frequently railing at their mistresses. *Arbutnot.*

LIVERY, in dress and equipage, a certain color and form of dress, by which noblemen and gentlemen distinguish their servants. Liveries are usually taken from fancy, and continued in families by succession. The ancient cavaliers, at their tournaments, distinguished themselves by wearing the liveries of their mistresses: thus

people of quality make their domestics wear their livery. The Romish church has also her several colors and liveries; white for confessors and virgins, and in times of rejoicing; black for the dead; red for the apostles and martyrs; blue or violet for the penitents; and green in times of hope. Liveries were abolished in France by the Constituent National Assembly, as badges of servitude, inconsistent with their system of equality, but have of course been since resumed.

THE LIVERYMEN OF LONDON are a number of men chosen from among the freemen of each company. Out of this body the common-council, sheriff, and other superior officers for the government of the city are elected; and they alone have the privilege of giving their votes for members of parliament for the city. See *LONDON*.

LIVIA, the second wife of the emperor Augustus, and mother of Tiberius, a woman of great beauty and ability, but of a very loose and depraved character. She was the daughter of L. Drusus Calidianus, and the wife of Tiberius Claudius Nero, one of Antony's adherents; by whom she was pregnant, when Augustus saw her, and married her; for which purpose he divorced his wife Scribonia. To ensure the succession to her son, she secretly procured the death of Augustus's grand-children and nearest relations. See *ROME*. She died A. D. 29, aged eighty-six.

LIVID, *adj.* } Fr. *livide*; Lat. *lividus*.

LIVIDITY, *n.s.* } Discolored, as by a blow; purple-colored.

It was a pestilent fever, not seated in the veins or humours, for that there followed no carbuncles, no purple or *livid* spots, the mass of the blood not being tainted. *Bacon*.

They beat their breasts with many a bruising blow,
Till they turned *livid*, and corrupt the snow.

Dryden.

The signs of a tendency to such a state, are darkness or *lividity* of the countenance. *Arbutnot*.

Days lay she in that state, unchanged, though chill.

With nothing *livid*, still her lips were red;

She had no pulse, but death seemed absent still;

No hideous sign proclaimed her surely dead.

Byron.

LIVINGSTON (William), a statesman and author of the United States of America, was born at New York, in 1723. During the contest for independence he employed himself in defending his country's cause; and after having filled various important situations in his native city, became a member of congress for New Jersey: on the establishment of the constitution, he was made governor of the state. He died at Elizabeth-town in 1790, having held the government twelve years. He was the author of *Philosophical Solitude*, a poem; *A Review of the Military Operations in North America*, from 1753 to 1758; and several other works.

LIVIVS (Titus), the celebrated Roman historian, was born at Patavium. Few particulars of his life have been handed down to us: We first hear of him at Rome, where he acquired

the notice and favor of Augustus. He had previously written *Dialogues*, historical and philosophical, and some books on philosophy. It is probable that he began his History as soon as he was settled at Rome. He used to read parts of it, while he was composing it, to Mæcenas and Augustus; and the latter appointed him to superintend the education of his grandson Claudius, afterwards emperor. After the death of Augustus, Livy returned to the place of his birth, where he was received with honor and respect; and where he died in the fourth year of Tiberius's reign, aged above seventy. Some say he died on the same day with Ovid; it is certain he died the same year. Scarce any man was ever more honored, in life or after his death, than this historian. A monument was erected to him in the temple of Juno, where was afterwards founded the monastery of St. Justina; and where, in 1413, was discovered the following epitaph:—*'Ossa Titi Livii Patavini, omnium mortalium judicio digni, cujus prope invicto calamo invicti populi Romani res gestæ conscriberentur.'*—The bones of Titus Livius of Patavium, a man worthy to be approved by all mankind, by whose almost invincible pen the acts and exploits of the invincible Romans were written.' These bones are said to be still preserved with high veneration by the Paduans. In 1451 Alphonsus, king of Arragon, sent his ambassador Anthony Panormita, to desire of the citizens of Padua the bone of that arm with which this their famous countryman had written his history: and, obtaining it, caused it to be conveyed to Naples with the greatest ceremony as a most invaluable relic. He is said to have recovered from an ill state of health by the pleasure he found in reading this history: and therefore, out of gratitude, took this method of doing honor to the memory of the writer. Panormita also, who was a native of Palermo in Sicily, and one of the ablest men of the fifteenth century, sold an estate to purchase this work. The history of Livy is transmitted down to us exceedingly mutilated and imperfect. Its books were originally 142, of which only thirty-five are extant. The epitomes of it, from which we learn their number, all remain, except those of the 136th and 137th books. Livy's books have been divided into decades, which some will have to have been done by Livy himself, because there is a preface to every decade; while others suppose it to be a modern contrivance, as nothing about it is mentioned by the ancients. The first decade is extant, and treats of the affairs of 460 years. The second is lost; the years of which are seventy-five. The third is extant, and contains the second Punic war, including eighteen years. It is reckoned the most excellent part of the history. The fourth contains the Macedonian and Asiatic wars, which take up the space of about twenty-three years. The first five books of the fifth decade, were found at Worms by Simon Grynaeus, in 1431, but are very defective; and the remainder, which reaches to the death of Drusus in Germany in 746, together with the second decade, are supplied by Freinshemius. The encomiums bestowed upon Livy, by both ancients and moderns, are great and numerous. But his probity, candor, and impartial-

lity, have distinguished him above all historians; for neither complaisance to the times, nor his particular connexion with the emperor, could restrain him from speaking so well of Pompey, that Augustus called him a Pompeian. Livy has been censured, and perhaps with justice, for being too credulous, and loading his history with superstitious tales. But though he mentions that milk and blood were rained from heaven, or that an ox spoke, or a woman changed her sex; yet he candidly confesses, that he recorded only what made an indelible impression upon the minds of a credulous age. Quintilian says, that he had a sor, to whom he addressed some excellent precepts in rhetoric. An ancient inscription speaks also of one of his daughters, named Livia Quarta; the same, perhaps, who espoused an orator of the name of Lucius Magius, whom Seneca mentions; and observes, that the applauses he usually received from the public in his harangues, were not so much on his own account, as for the sake of his father-in-law. Livy's history has been often published with and without the supplement. The best editions are that of Gronovius, cum notis variorum et suis, Lugd. Bat. 1679, 3 vols. 8vo.; that of Le Clerc, at Amsterdam, 1709, 10 vols. 12mo.; and that of Crevier, at Paris, 1735, 6 vols. 4to. A fragment of Livy's history was published in 1773, by Dr. Bruns.

LIVIVS ANDRONICUS, a comic poet, who flourished at Rome about A. A. C. 240. He was the first who turned the personal satires and fescennine verses into the form of dialogue and regular drama. Though the character of a player was reckoned despicable among the Romans, Andronicus acted a part in his dramatical compositions. He was a freed man of M. Livius Salinator, whose children he educated. His poetry was grown obsolete in the age of Cicero.

LIVONIA, a maritime province of the north-west of Russia in Europe, bounded by Esthonia on the north, and Courland on the south. It has an area of 21,000 square miles; but a population of not above 600,000, and consists of a vast tract of level marshy country, and several hundred lakes, great and small. Those of Peipus, Ljuban, and Wirzjev, are of considerable size. The soil is in general a rich loam, well calculated for tillage or pasturage; and it exports rye, barley, flax, hemp, and linseed. The cattle are small.

This country, which has been often the seat of war, was almost unknown to the south of Europe to the end of the twelfth century, when it was overrun by the Danes. It was, during the thirteenth and fourteenth centuries, governed by the Teutonic knights; and in the sixteenth the Poles acquired it. In the seventeenth century Russia and Sweden contested the possession of it; but in 1660 it was ceded to the latter by the peace of Olivia. The vice of drunkenness is said to be here particularly prevalent, and the wretchedness of the lower orders extreme. Edicts have recently been issued to lighten their vassalage; but a long time must elapse before they can produce a substantial result. Dorpat is the only university here, and Riga the only place of much trade.

LIXIVIAL, *adj.* } Lat. *lixivium*; Fr. *lixiv*.
LIXIV'ATE, *adj.* } *vieux*. Impregnated with
LIXIV'UM, *n. s.* } salts like a *lixivium*; ob-
tained by *lixivium*: *lixivate*, making a *lixivium*:
lixivium, lie; water impregnated with alkaline
salt; having the power of extraction.

In these the salt and *lixivated* serosity, with some portion of choler, is divided between the guts and the bladder.

Broune.
Lixivate salts, to which pot-ashes belong, by piercing the bodies of vegetables, dispose them to part readily with their tincture.

Boyle.
I made a *lixivium* of fair water and salt of wormwood, and, having frozen it with snow and salt, I could not discern any thing more like to wormwood than to several other plants.

Id.
Helmont conjectured, that *lixivial* salts do not pre-exist in their alcalizate form.

Id.
The symptoms of the excretion of the bile vitiated, were a yellowish color of the skin, and a *lixivial* urine.

Arbuthnot.
Lixivation is the separation, by means of water, or other fluid, of such substances as are soluble in the fluid from other substances that are not soluble in it.

Amison's Elements.
And, as the hydriodate of potash is very soluble and even a deliquescent salt, this circumstance accounts for its remaining in the mother-liquor during the subtraction of the subcarbonate of soda and other neutral salts from the alkaline *lixivium* by the usual process of evaporation. *Parke's Chemical Catechism.*

LIXURI, a town of the island of Cefalonia, Greece, having 6000 inhabitants. It has a harbour and a considerable trade, but has often suffered from earthquakes.

LIZARD ISLAND, one of the Direction islands in the South Pacific Ocean, is about 240 miles in circumference, rocky and barren. This name was given to it by captain Cook, from the number and large size of the lizards found here. It is twenty miles north-east of Cape Flattery.

LIZARD POINT, in Cornwall, the most southern point of England; whence ships bound westward usually take their departure. It is 282 miles south-west of London, and in long. 5° 11' 17" W., lat. 49° 57' 55" N.

LIZARD, *n. s.* Fr. *lizard*; Lat. *lacerta*. An animal resembling a serpent, with legs. See LACERTA.

And the lizard, and the snail, and the mole. These are unclean to you.

Thou'rt like a foul mis-shapen stigmatick,

Marked by the destinies to be avoided,

As venomous toads, or lizards dreadful stings.

Shakespeare.
There are several sorts of lizards; some in Arabia of a cubit long. In America they eat lizards; it is very probable likewise that they were eaten in Arabia and Judea, since Moses ranks them among the unclean creatures.

Cutler.
LIZARD. See LACERTA.

LLANDAFF, a city of Glamorganshire, 16 miles north-west from Cardiff, and 163 from London. Its name is supposed to be a corruption of Llan-ar-daff, Welsh, the church on the Taff, the walls of the church-yard being close to the river. The present structure was built by bishop Urban in 1120; it had two towers at the west end, eighty-nine feet high, of which that on the south only remains. The north tower was rebuilt in an elegant manner in the reign of Henry VII. The body of its ancient cathedral.

has been rebuilt. Among the ancient monuments of the bishops interred in this church, there is one representing an emaciated corpse in a winding-sheet, in which the appearance of death brought on by a long sickness is admirably portrayed. The ecclesiastical establishment consists of the bishop, archdeacon, twelve prebendaries, and two vicars choral. The episcopal see was founded about the end of the fifth century. This diocese includes great part of the counties of Glamorgan and Monmouth, and though this is styled a city, from being the see of a bishop, it is without a market. It has the benefit of a tolerably good harbour, that opens into the Severn at four miles distance. Fairs 9th of February and Whit-Monday.

LLANOS, the name given in South America to the vast level plains that occur in Colombia and other countries. In Colombia alone the area of the Llanos is estimated at 296,800 square miles. They are sometimes sandy, often covered with vegetation, and are supposed to have once been the bottom of the ocean.

LLANOS, SAN JUAN DE LOS, a province of the former kingdom of New Granada, bounded on the north by Varinas and Merida, on the east by Varinas, on the west by Santa Fe and Popayan, and south by the government of Quixos, and extending to the immense length and breadth of from 200 to 300 leagues. It is watered by the Apure, Meta, Casanari, and Orinoco. The soil is fertile, but the climate immoderately hot, especially on the widely extended plains, which the long grass shelters from all winds. In some of them Humboldt found the thermometer rise to 115°. Here were several missions, established by the monks of Santa Fe de Bogota and the Jesuits; but little is known concerning them.

LLANOS, SAN JUAN DE LOS, the capital of the above province, was formerly celebrated for the gold mines of its neighbourhood. It was founded in 1555; and is fifty miles E. S. E. of Santa Fe de Bogota. Long. 73° 55' 30" W., lat. 3° 11' N. This is also the name of several inconsiderable settlements of Spanish America.

LLANRWST, a market-town and parish of Denbighshire, twelve miles south from Aberconway, and 218 north-west from London; standing on the banks of the river Conway, over which it has a simple elegant bridge of three arches, built in 1636. The church is a plain building, adjoining which is a chapel built by one of the Wynne family. The river is navigable for small vessels within a mile and a half below the town. Near Llanrwst stands Gwydir House, the seat of lord Willoughby, an extensive pile, which marks the splendor of its ancient possessors. This town was in the high road from Shropshire to Holyhead, and, being the only market town in this part of the country, it is the centre of all the business of the populous vale in which it stands. It has a good market-house, and a free-school. Market-day Tuesday.

LLANTRISSANT, a borough, market-town, and parish of Glamorganshire, ten miles north-west from Llandaff, and 170 west from London. It is pleasantly seated on the side of a steep hill, the property of the marquess of Bute, which abounds in lead-ore. Its name signifies

the church of the three saints; the church being dedicated to St. Ilhog, St. Devong, and St. Monow. The streets are steep and narrow, but many of the houses are tolerably well-built, and the prospects are picturesque. The town-hall and market-house were both erected by the late earl of Bute. Its ancient castle is in ruins. This borough is governed by a portreeve, and with Cardiff, Swansea, &c., unites in sending one member to parliament. Market on Friday.

LLORENTE (Don Juan Antonio), a modern Spanish historian, was chancellor of the university of Toledo, and a member of the Inquisition; a complete history of which, from the period of its establishment by Ferdinand V., was published by him, and translated into English in 1817. He accepted a situation under Joseph Buonaparte, and was therefore driven into exile on the return of Ferdinand; but being also expelled from France, by the influence of the court of Rome, he returned secretly to Madrid, where he died in the spring of 1823.

LLOYD (Nicholas), a learned lexicographer, in the seventeenth century, born in Flintshire, and educated at Wadham College, Oxford. He was rector of Newington, near Lambeth, in Surry, till his death in 1680. His *Dictionarium Historicum*, is a valuable work, to which Hoffman and Moreri are greatly indebted.

LLOYD (Robert), an English poet, son of Dr. Pierson Lloyd, second master of Westminster school, where Robert was educated. He took his degree of M.A. at Cambridge. He published a poem, entitled the Actor, in 1760, the merit of which was so great, that, when the Rosciad appeared, he was supposed to be the author of that also. He was employed as usher at Westminster school, but lost it by his irregularities; and afterwards lived almost entirely on the generosity of his friend Churchill, the poet. He died in 1764. His poems were published by Dr. Kenrick, in 2 vols. 8vo. He also wrote the *Capricious Lover*, a comic opera, 1764, 8vo., and other dramatic pieces.

LLOYD (William), D.D., a learned English bishop, born in Berkshire in 1627, and educated under his father, who was vicar of Tylehurst in Berkshire. He entered into orders at Oxford; in 1660 was made prebendary of Ripon; and in 1666 chaplain to the king. In 1667 he graduated; in 1672 he was installed dean of Bangor; and in 1680 was consecrated bishop of St. Asaph. He was one of the seven bishops who were imprisoned in the tower, for subscribing a petition to the king against his declaration for liberty of conscience. Soon after the revolution he was made almoner to king William and queen Mary: in 1692 bishop of Lichfield and Coventry; and in 1699 of Worcester, where he sat till his death in 1717, in the ninety-first year of his age. His works are much esteemed.

LLOYD (Henry), a military officer and eminent writer on tactics, born in Wales, in 1729, was the son of a clergyman, who instructed him in the mathematics and classical literature. At the age of seventeen he went abroad, and he was present at the battle of Fontenoy. He afterwards travelled in Germany; and having resided some years in Austria, he was appointed aid-de-camp

to marshal Lascy. He was gradually promoted, till, in 1760, he was intrusted with the command of a large detachment of cavalry and infantry, destined to observe the movements of the Prussians. Lloyd executed this service with great success; but soon after resigned his commission in disgust. He was then employed by the king of Prussia; and during two campaigns, he acted as aid-de-camp to prince Ferdinand of Brunswick. After the peace of Hubertsburg, he travelled, till the occurrence of hostilities between Russia and Turkey, when he offered his services to Catharine II., who made him a major-general. He distinguished himself in 1774, at the siege of Silistria; and, subsequently, he had the command of 30,000 men, in the war with Sweden. At length, he left Russia, and travelled in Italy, Spain, and Portugal. He visited general Eliott, at Gibraltar, whence he proceeded to England. Having made a survey of the coasts of the country, he drew up a Memoir on the Invasion and Defence of Great Britain, which was published in 1798. He retired, at length, to Huy, in the Netherlands, where he died, June 19, 1783. Besides the memoir he was the author of an Introduction to the History of the War in Germany, between the king of Prussia and the Empress-Queen; and a Treatise on the Composition of Different Armies Ancient and Modern. These works have been translated into French and German, and Jomini made use of the Introduction for his 'Traité des Grandes Opérations Militaires.' Other works of Lloyd's are said to have been brought up and suppressed by the government, and many of his papers are said to have been taken possession of, at his death, by a person supposed to be an emissary of the English ministry, among which were the Continuation of the History of the Seven Years' War, and a History of the Wars in Flanders.

LOYD'S LIST, a publication in which the sweeping news of the British empire is published, and which contains the earliest and most authentic information. It takes its name from Lloyd's Coffee House, in the Royal Exchange of London, whence the information contained in the list is obtained.

LO! *interj.* Sax. and Teut. lo, la, imperative f Look, to which refer. See; behold!

For lo! he sung the world's stupendous birth.

Roscommon.

LOACH, *n. s.* Fr. *loche*; Lat. *lotus*. A fish; the COBITIS, which see.

The loach is a most dainty fish; he breeds and feeds in little and clear swift brooks or rills, and lives there upon the gravel, and in the sharpest streams: he grows not to be above a finger long, and no thicker than is suitable to that length: he is of the shape of an eel, and has a beard of wattels like a barbel: he has two fins at his sides, four at his belly, and one at his tail, dappled with many black or brown spots: his mouth, barbel-like, under his nose.

Walton's Angler.

LOAD, *n. s.* & *v. a.* Sax. *hlæde*; Swed. *lada*; Ital. *lade*; Teut. *laden*. Preterite loaded; part. loaded, loaden or laden. A burden; weight; freight; pressure: hence violence of blows; any thing that depresses; as much of drink, or any other thing, as can be borne.

LOAD, or
LODE, *n. s.*

LOADS'MAN,

LOAD'STAR,

LOAD'STONE,

More properly written }
lode; Sax. *hlæban*, to lead; }
Goth. *lod*, *leid*; Dan. *lood*. }
Signifying respectively, the }
leading vein of a mine; a }
leading man or pilot: leading star, i.e. the pole- }
star, or cynosure: leading stone, i.e. the magnet }
by which mariners are led or directed.

And this sterre, that is toward the Northe, that wee clepen the lode sterre ne apperethe not to hem.

Sir J. Mandeville.

Then saw I how woful Calistope,
Whan that Diane agreved was with here,
Was turned from a woman til a bere,
And afir was she made the lode-sterre.

Chaucer. Cant. Tales.

My Helice, the loadstar of my life.

Spenser.

Their manner of working, in the lead mines, is to follow the lode as it lieth.

Carew's Survey of Cornwall.

O happy fair!

Your eyes are loadstars, and your tongue sweet air!
More tuneable than lark to shepherd's ear
When wheat is green, when hawthorn buds appear.

Shakspeare.

That clear majesty

Which standeth fixed, yet spreads her heavenly worth,

Lodestone to hearts, and loadstar to all eyes.

Darvies.

She was the loadstar of my life; the blessing of mine eyes; she the overthrow of my desires, and yet the recompence of my overthrow.

Sidney.

The grace of God's spirit, like the true loadstone or adamant, draws up the iron heart of man to it; and holds it in a constant fixedness of holy purposes and good actions.

Bp. Hall.

The use of the loadstone was kept as secret as any of the other mysteries of the art.

Swift.

The loadstone is a peculiar and rich ore of iron, found in large masses, of a deep iron-grey where fresh broken, and often tinged with a brownish or reddish color; it is very heavy and considerably hard, and its great character is that of affecting iron. This ore of iron is found in England, and in most other places where there are mines of that metal.

Hill's Materia Medica.

LOAD, or LODE, is used, particularly in the tin mines, for any regular vein or course, whether metallic or not; but most commonly for a metallic vein. Mines in general are veins or cavities within the earth, whose sides, receding from or approaching to each other, make them of unequal breadths in different places, sometimes forming large spaces, which are called holes; these holes are filled like the rest with substances, which, whether metallic, or of any other nature, are called loads. When the substances forming these loads are reducible to metal, the loads are by the English miners said to be alive, otherwise they are termed dead loads. In Cornwall and Devonshire the loads all hold their course from east to west, though in other parts of England they frequently run from north to south. The miners report, that the sides of the load never bear in a perpendicular, but always overhang either to the north or south above. The mines seem to have been so many channels through which the waters pass within the earth; and like rivers they have their small branches opening into them in all directions: these are by the miners termed the

feeders of the load. Most mines have streams of water running through them; and, when they are found dry, it seems owing to the water having changed its course; which it seems sometimes to have been compelled to do, by the load having filled up the course, and sometimes to have fallen into other more easy channels. The load is frequently intercepted by the crossing of a vein of earth or stone, or some other metalline substance; in which case it generally happens, that one part of the load is moved to a considerable distance on one side. This transient load is, by the miners, termed a *flooding*; and the part of the load which is moved is by them said to be heaved. This fracture or heave of a load, according to Mr. Price, is produced by a subsidence of the strata from their primary positions, which he supposes to have been horizontal or parallel to the surface of the earth, and therefore should more properly be called a depression than a heave. This heaving of the load would be an inexpressible loss to the miner, did not experience teach him, that, as the loads always run on the sides of the hills, so the part heaved is always moved towards the descent of the hill; so that the miner, working towards the ascent of the hill, and meeting a *flooding*, considers himself as working in the heaved part; wherefore, cutting through the *flooding*, he works upon its back up the ascent of the hill, till he recovers the load, and vice versa. See *MINE*.

LOADED SHELL, an ingenious contrivance for saving the lives of people in imminent danger, on board a ship, when the vessel is either stranded, or in danger of being so, near the coast. It is a bomb-shell filled with lead, wherein a staple or ring is fixed, to which a rope is fastened; and the shell, thus loaded, being thrown on shore, fixes itself in the ground, and, the other end of the rope being fastened to the ship, the persons on board are thereby enabled to haul themselves ashore. It was invented by John Bell, serjeant of the royal regiment of artillery, who obtained a premium for it of fifty guineas in 1792, from the Society for the Encouragement of Arts, &c., after exhibiting its utility and practicability before a committee of the society. On this occasion a loaded shell, weighing about seventy pounds, was thrown on shore, from a small mortar fixed on a boat, moored in the Thames, about 200 yards from the coast. The shell, falling about 100 yards within land, buried itself about eighteen inches in the gravel, when Bell and his assistant, on a raft floated by casks properly allasted, hauled themselves ashore in a few minutes by the rope affixed to the shell.

LOADSTONE. See *MAGNET*.
LOAF, *n. s.* Sax. *hlaf*, *laf*; Goth. *hleif*, *laf*; Sax. *plafian*; Lat. *levo*, to raise up. See *HEAVEN*. A mass or large portion of bread: hence masses of other bulky articles.

And thei forgotten to take bread, and thei haddan ot with hem but oo loaf in the boot.

Wiclif. Mark 8.

Easy it is
 Of a cut loaf to steal a shive we know.

Shakspeare.

Democritus, when he lay a dying, caused loaves of ew bread to be opened, poured a little wine into

them; and so kept himself alive with the odour till a feast was past.

Bacon.

The bread corn in the town sufficeth not for six days: hereupon the soldiers entered into proportion; and, to give example, the lord Clinton limited himself to a loaf a-day.

Hayward.

With equal force you may break a loaf of bread into more and less parts than a lump of lead of the same bigness.

Digby.

Your wine becomes so limpid, that you may bottle it with a picce of loaf sugar in each bottle.

Mortimer.

It undergoes in Europe several refinings in order to form it into loaf sugar.

Parke's Chemical Catechism.

LOAM, *n. s.* & *v. a.* } Sax. *laam*; Teutonic

LOAM'X, *adj.* } *leim*; Lat. *limus* (of Gr.

λῆμν, a fen, says Junius). Rich tenacious earth; marl.

Men are but gilded loam or painted clay.

Shakspeare.

Alexander returneth to dust; the dust is earth: of earth we make loam; and why of that loam might they not stop a beer barrel?

Id.

The mellow earth is the best, between the two extremes of clay and sand, if it be not loamy and binding.

Bacon.

Auricula seedlings best like a loamy sand, or light moist earth; yet rich and shaded.

Evelyn.

The joist ends, and girders which be in the walls, must be loamed all over, to preserve them from the corroding of the mortar.

Moxon's Mechanical Exercises

LOAN, *n. s.* Sax. *plæn*, *lan*; Goth. and Swed. *lan*. Something lent; amount of monies lent or bargained for in the way of borrowing.

The better such ancient revenues shall be paid, the less need her majesty ask subsidies, fifteens, and loans.

Bacon

You're on the fret,

Because, in so debauched and vile an age,
 Thy friend and old acquaintance dares disown
 The gold you lent him, and forswear the loan.

Dryden.

As none but kings have power to raise

A levy, which the subject pays,

And tho' they call that tax a loan,

Yet when 'tis gathered 'tis their own.

Butler

LOANS, in modern finance, are the basis of the funding system, and the reader will find their general effect on the finances of this country traced in our article *FUNDS*.

The British mode of negotiating loans is there particularly pointed out. Very extensive contracts of this nature have however of late been made in this country by the agents of foreign governments. The terms of the loan required are stated to one of the larger merchants or bankers, the security offered, &c., and this house and its friends have the management of the loan, and the payment of the dividends upon it. There is hardly a civilised state in the world that has not raised money in this way in London since the peace of Paris. These loans have, we fear, in many instances, proved any thing but what their name would import, i. e. money advanced with the prospect of its being returned. Minor states, however, have thus participated in the wealth of more established communities; in some cases (as in the mercantile Greek loans) they have received but a small share of advan-

tage from their pledged resources; and these measures as interlinking the prosperity of numerous and distant nations are a species of security, perhaps, against the frequent recurrence of wars.

LOAN-BANKS, or lending-houses, were establishments of an ancient date, supported by humane persons, with a view of lending money to the poor. The emperor Augustus we are told converted into a fund the surplus of the money which arose to the state from the confiscated property of criminals, and lent sums from it, without interest, to those who could give security for its return, equal to double the amount. Suet. Vit. Augusti, cap. 41. Tiberius also advanced a large capital, from which those were supplied with money, for three years, who could give security of this kind in land. Suet. Vit. Tiberii, cap. 48. Tacit. Annal. vi. 17. Dio Cassius, cap. viii. 21. Alexander Severus also advanced certain sums at a low rate, to the poor without interest to purchase lands, and received payment from the produce of them. Æl. Lamprid. Vit. Alex. Severi, cap. 21.

In modern Italy, the pontiffs at first patronised the erection of lending-houses to advance money to the poor without interest; then they allowed these houses to receive interest, not for the whole capitals which they lent, but only for a part, that they might raise money sufficient to defray their expenses. In process of time, under pretext of improving their resources for the public benefit, it was thought proper, to give to those who should advance money a moderate interest concealed by blending it with the unavoidable expenses of their establishments. The interest received was said to be 'pro indemnitate;' in the papal bulls, and the pope declared the lending-houses or 'holy mountains of piety,' as they were called, to be legal; threatening those with vengeance who dared to entertain any doubts on the subject. Most of the Italian cities now therefore established lending-houses: their origin, in the strict sense of the term, is referred to the time of Pius II. or Paul II., but the greater part of them were established in the fifteenth and following centuries by certain Minorites. The Dominicans exclaimed against these institutions as montes impietatis, and the dispute respecting them was agitated with so much warmth in the beginning of the sixteenth century, that Leo X. was obliged in the council of the Lateran to declare by a particular bull, that lending-houses were legal and useful; that all doubts to the contrary were sinful; and that those who should write against them would be in a state of excommunication. The holy council of Trent also decreed their legality, and confirmed their use.

LOANDO, or LOANDO ST. PAUL'S, the capital of the Portuguese settlements in Angola, Southern Africa, was founded in 1578. It covers a large extent of ground, but the white population is not more than 3000 in number; the number of negroes is perhaps 5000. Provisions are plentiful; but the water is bad, and must be brought, either from a neighbouring river, or the opposite island of this name. Loando contains three convents, and is the seat of

a bishop, but is wholly without forts and ever walls. Long. 13° 22' E., lat. 8° 55' S.

LOANDO, the island opposite to the foregoing city, is about twenty miles long, and one broad. It is separated from the continent by a narrow channel, which the natives often swim across. It produces goats and sheep, and contains seven or eight villages. The citizens have a number of country houses and gardens here. It yields the best water in all the neighbourhood. Lat. 8° 50' S.

LOANGO, a considerable, but unexplored country of Western Africa, to the north of the river Zaire or Congo. The country, which owns the supremacy of the king, is said to extend from Cape St. Catherine to the Zaire, having a coast of upwards of 400 miles: Loango Proper occupies only the middle part of this space. The character of the whole coast is very similar, and is thus described by captain Tuckey in his Maritime Geography:—

Mayumba, or Alvarez Martin's Bay, is three leagues wide between Cape Primero on the north, which takes in three saddle hills, and Cape Secondo, or Matooty, on the south, from which a reef runs out to the north one mile and a half; and off Cape Primero is a sunken rock with but two fathoms and seven fathoms all round. This bay affords good anchorage in four to seven fathoms. Ten leagues south of Mayumba is Cape Sellage, on the south side of which, and close to the main, is a small island, and two leagues farther south, and three leagues off shore, a reef of breakers. Kilonga River is sixteen leagues south of Cape Sellage, and is closed by a bar that admits only canoes; it is known by a hill on the north, with a knob on the summit; north of the river's mouth is a large lagoon. Seven leagues south of Kilonga is Moutas River, crossed by a bar of sand and stones, on which the depth is two fathoms.

Loango Bay is surrounded by red cliffs. From its south point a reef, called the Indian Bar, runs nearly half way across the bay, but within it is good anchorage in four fathoms, three quarters of a mile from the shore. The surf, however, prevents landing, except in the canoes of the country. Within the beach is a lagoon, named Barachonas, which communicates with the sea through the beach, or rather in high surfs the waves beat over the beach; but, when the sea outside is smooth, the beach remains dry, and the lagoon empties itself by filtration and evaporation: when half empty it may be passed on foot, but when full it is extremely dangerous.

Sixteen leagues south of Loango is Malemba; an open road, the approach to which is denoted by the high mountains of Caongo, which rise behind a bay of the same name, into which falls a little river: the anchorage in this bay is bad. Malemba is a mountain, rising perpendicularly from the water to the height of seventy fathoms, and descending towards the land; before it is a bar of volcanic rocks, one mile and a half from the shore, which is sometimes dangerous to pass, but, when within it, landing is perfectly commodious, in a little cove called Paradise, or Canoe Cove, and in another, named Sloops Cove, is the watering place; the latter is, however, beat by

the surf, through which the casks are obliged to be swam, not without risk from the sharks. The anchorage is outside the bar, a league and a half from the shore. The trading place is on the summit of the mountain, the ascent to which is through a ravine formed by the rains, and is difficult and surrounded by precipices, so that a false step may endanger life. Goats, hogs, and fruit, are abundant at Malemba, and a great slave trade was formerly carried on here by the French. A league and half to the south-east is the lagoon of Loanguilly abounding with fresh water fish.

Cabenda, five leagues south of Malemba, is named the Paradise of the Coast, from its agreeable situation, and the facility of landing. It is known by a single sugar-loaf mountain, covered with wood. The south point of the bay is named Cabenda Hook, or Palm-tree Point: it is long, low, and covered with palm-trees, and shelters the bay on the south. The anchorage is within this point, in four fathoms, within two miles of the shore, the hook bearing S. S. W. and the sugar loaf E. S. E.; a small river falls into the bay, and receives boats at its mouth; half a mile above which the water is fresh, but is said to be unwholesome. There is also another watering place a little south of the point of the hook on the side of the sea: the surf here renders watering difficult, but the water which issues from a spring is excellent. The tide never rises by the shore more than one inch and a half. The bay abounds in fish, and has good places for hauling the seine.

Half way between Malemba and Cabenda is the little river Bela, off which is a line of banks of the same name, whose north extremity is a league and a half south of the anchorage in Malemba. Their approach is dangerous, as there is seven fathoms close alongside of them; hence vessels sailing from Malemba to the south are cautioned to keep off in twelve fathoms. On these banks are taken great quantities of fish. The coast of Congo commences at the river Zaire.

The climate is said to be fine, and never subject to hurricanes, nor even to violent winds. Rain occurs rarely, and is never violent: while the dews are sufficient for vegetation. The winter is in May, June, and July, when the nights are cooler, but without being chill. The soil is in general a red stiff clay, very fertile; the sand on the coast is extremely fine, and carried about by the lightest breeze. The coast is high; but the hills are covered with earth and luxuriant vegetation. The lakes and rivers abound with fish, and the forests with game. But the bounties of nature are little improved by an indolent people. Almost the only grains grown are manioc, maize, and a species of pulse called msangen. The women just stir the ground to the depth of an inch, and cover up the grain, to prevent it from being devoured by the birds: and even this slender culture is confined to little spots like gardens, situated around the villages. The rest of the country is covered with luxuriant herbs, rising to the height of eight feet, through which it is almost impossible to pass. The potatoe and yam are abundant. The most remarkable tree is the mapon, distinguished, like the boabab, by the enormous dimensions of its trunk: but it

affords neither fruit, shade, nor fuel, and forms thus a striking contrast to the extreme utility of the cocoa tree, which also abounds. Palm trees are also plentiful.

The wild animals are hyænas, tyger-cats, and ounces. The hare, antelope, and Chinese hog, are also seen: but it is remarkable that neither the horse, the cow, the sheep, nor the ass, have multiplied in this country.

It is obvious that the population of this coast cannot be in proportion to its extent. The inhabitants are not supposed by Degrandpré to exceed 600,000. Their houses are of straw and junk, roofed with palm-leaves cemented by twigs. Their grandees, and even kings, have only a number of these upon the same plan.

The government here is despotic, and the dignity transmitted only it is said in the female line. The son even of the king, by a female of ordinary rank, enjoys no dignity above the rest of the subjects. The princesses choose their own husband, who does not enjoy the liberty of declining the honor; and who is entirely debarred from that privilege of polygamy which is enjoyed in the most unlimited measure by other nations. He is prevented, if possible, even from seeing any other woman.

The object for which Europeans have resorted to this coast is the disgraceful one of the trade in slaves. The coast to the south of the Zaire is almost entirely in the possession of the Portuguese. While Loango was in the height of its power, its port was almost the exclusive theatre of this trade; but now Mayumba, Malemba, and Cabenda are as much frequented.

LOANGO, the capital of the above kingdom of Loango, is about four miles in circuit, but does not contain a population of above 15,000, and there are not in the whole above 600 enclosures. The land in the vicinity is fertile, and the water excellent. It is not above a league from the sea. The entrance of the bay we have described. It is recognised by red cliffs, which, illumined by the morning rays, appear as if on fire. The longitude, according to captain Tuckey's observations, appears to be about $12^{\circ} 30' E.$, lat. $4^{\circ} 40' N.$

LOATH, <i>adj.</i>	Sax. <i>lað, laðian</i> ;
LOATH'E, <i>v. a. & v. n.</i>	Teut. <i>leiden</i> , to dislike.
LOATH'FUL, <i>adj.</i>	Unwilling; uninclined;
LOATH'INGLY, <i>adv.</i>	unready; averse;
LOATH'LY, <i>adj. & adv.</i>	to loathe is to hate; ab-
LOATH'NESS, <i>n. s.</i>	hor; disrelish; feel ab-
LOATH'SOME, <i>adj.</i>	horrence or disgust;
LOATH'SOMENESS, <i>n. s.</i>	and, in an obsolete

sense, to create disgust: loathly is used both for hateful and exciting hatred; as well as adverbially for unwillingly; without liking: loathsome is also abhorred or causing abhorrence or disgust.

The fish in the river shall die, and the river stink;
and the Egyptians shall loath to drink of the water.

Exodus.

For on my portos here I make an othl,
That never in my lif, for lefe ne loth,
Ne shal I of no conseil you bewray.

Chaucer. Cant. Tales.

When he heard her answers loth, he knew
Some secret sorrow did 'e heart distress.

Faerie Queene

l

They with their filthiness
Polluted this same gentle soil long time,
That their own mother *loathed* their beastliness.
Spenser.

Where I was wont to seek the honey bee,
The grisly toadstool grown there might I see,
And *loathing* paddocks lording on the same. *Id.*

An huge great dragon, horrible in sight,
Bred in the *loathy* lakes of Tartary,
With murderous ravin. *Faerie Queene.*

Before such presence to offend with any the least
unseemliness, we would be surely as *loth* as they who
most reprehend or deride what we do. *Hooker.*

Which he did with *loathful* eyes behold,
He would no more endure. *Hubbard's Tale.*

To speak so indirectly, I am *loath* ;
I'd say the truth ; but to accuse him so,
That is your part.

Shakspeare. Measure for Measure.

Sour-eyed disdain and discord shall bestow
The union of your bed with weeds so *loathly*,
That you shall hate it. *Id. Tempest.*

Lothly opposite I stood
To his unnatural purpose.

Id. King Lear.

Should we be taking leave,
As long a term as yet we have to live,
The *loathness* to depart would grow.

Shakspeare.

The sweetest honey
Is *loathsome* in its own deliciousness,
And in the taste confounds the appetite. *Id.*

After they had sat about the fire, there grew a
general silence and *lothness* to speak amongst them ;
and immediately one of the weakest fell down in a
swoon. *Racon.*

Long doth she stay, as *loth* to leave the land,
From whose soft side she first did issue make ;
She tastes all places, turns to every hand,
Her flowery banks unwilling to forsake. *Davies.*

This shows that you from nature *loathly* stray,
That suffer not an artificial day. *Donne.*

How *loth* is God to strike, that threats so long.
Bp. Hall.

Loathing the honey cakes, I longed for bread.
Cowley.

Then wilt thou not be *loth*
To leave this paradise, but shalt possess
A paradise within thee, happier far ! *Milton.*

While they pervert pure nature's healthful rules
To *loathsome* sickness. *Milton's Paradise Lost.*

Such indignities did add somewhat of *loathsomeness*
to his cup of affliction. *Barrow.*
Parthenia had learned both liking and misliking,
loving and *loathing*. *Sidney.*

To pardon willing, and to punish *loth* ;
You strike with one hand, but you heal with both ;
Lifting up all that prostrate lie, you grieve
You cannot make the dead again to live. *Walter.*

As some faint pilgrim standing on the shore,
First views the torrent he would venture o'er
And then his inn upon the farther ground,
Loth to wade through, and *lother* to go round
Then dipping in his staff does trial make
How deep it is ; and sighing, pulls it back.

Dryden.

Red blisters rising on their paps appear,
And flaming carbuncles, and noisome sweat,
And clammy dews, that *loathsome* lice beget ;
Till the slow creeping evil eats his ways.
Id. Virgil.

For thee the lion *loaths* the taste of blood,
And roaring hunts his female through the wood.
Dryden.

If we consider man in such a *loathsome* and pro-
voking condition, was it not love enough that he was
permitted to enjoy a being ? *South.*

Why do I stay within this hated place,
Where every object shocks my *loathing* eyes ?

Rowe.

The catacombs must have been full of stench and
loathsomeness, if the dead bodies that lay in them
were left to rot in open niches. *Addison.*

Loathing is a symptom known to attend disorders
of the stomach ; the cure must have regard to the
cause. *Quincy.*

Our appetite is extinguished with the satisfac-
tion, and is succeeded by *loathing* and satiety.
Rogers.

Now his exalted spirit *loaths*

Incumbrances of food and clothes. *Swift.*

Body and soul, like peevish man and wife,

United jar, and yet are *loath* to part. *Young.*

The occurrences of life, by the time we come to
know it a little, would be incapable of affecting the
mind with any other sensations than those of *loathing*
and weariness, if many things were not adapted to
affect the mind by means of other powers besides no-
velty in them, and of other passions besides curiosity
in ourselves. *Burke on the Sublime.*

The limb which it adorned, its only mould ;

So beautiful—its very shape would charm,

And clinging as if *loth* to lose its hold,

The purest ore inclosed the whitest skin

That e'er by precious metal was held in. *Byron.*

Thought of the gloomy day and ghastly night,

That dreads the darkness, and yet *loathes* the light,

That winds around, and tears the quivering heart !

Ah ! wherefore not consume it—and depart ? *Id.*

LOB, *n. s. & v. a.* } Belg. *los*, *loon* ; Swed.

LOB'S-POUND. } *lom*, slow. A sluggard :
a large earth worm : to *lob* is to let fall in a slow
sluggish manner : *lob's-pound*, a house of oor-
rection.

Farewel, thou *lob* of spirits, I'll begone,

Our queen and all her elves come here anon.

Shakspeare.

The horsemen sit like fixed candlesticks,

And their poor jades

Lob down their heads, dropping the hide and hips.
Id.

Crowderow, whom in irons bound,

Thou basely threw'st into *lob's pound*.

Hudibras.

For the trout the dew worm, which some also call
the *lob* worm, and the brandling, are the chief.

Walton's Angler.

LOB'BY, *n. s.* Teut. *laube*. The opening or
waiting place before a room, public or private

His *lobbies* fill with tendance,

Rain sacrificial whisperings in his ear,

Make sacred even his stirrup.

Shakspeare. Timon of Athens.

Before the duke's rising from the table, he stood
expecting till he should pass through a kind of *lobby*
between that room and the next, where were divers
attending him. *Wotton.*

Try your backstairs, and let the *lobby* wait,

A stratagem in war is no deceit. *King.*

LOBE, *n. s.* Fr. *lobe* ; Gr. *λοβος*. A division
distinct part : particularly a part of the lungs or
liver.

Nor could the *lobes* of his rank liver swell

To that prodigious mass, for their eternal meal.

Dryden.

From whence the quick reciprocating breath,

The *lobe* adhesive, and the sweat of death.

Swell.

Air bladders form lobuli, which hang upon the bronchia like bunches of grapes; these lobuli constitute the lobes, and the lobes the lungs.

Arbuthnot on Aliments.

LOBEL (Matthias), M. D., physician and botanist to king James I., was born at Lisle in 1538. He published several esteemed works, viz. 1. *Plantarum seu Stirpium Historia*, folio; 2. *Dilucidæ Simplicium Medicamentorum Explicationes, et Stirpium Adversaria, &c.*, folio; 3. *Icones Stirpium*, 4to.; 4. *Balsami Explanatio*, 4to.; 5. *Stirpium Illustrationes*, 4to. He died at London in 1616, aged seventy-eight.

LOBELIA, cardinal flower, a genus of the monogamia order, and syngenesia class of plants: natural order twenty-ninth, campanaceæ: cat., quinquefid: cor. monopetalous and irregular: caps. inferior, bilocular, or trilocular. There are many species, but only four are cultivated in our gardens; of these two are hardy herbaceous plants for the open ground, and two shrubby plants for the stove. They are all fibrous-rooted perennials, rising with erect stalks from two to five or six feet high, ornamented with oblong, oval, spear-shaped, simple leaves, and spikes of beautiful, monopetalous, somewhat ringent, five-parted flowers, of scarlet, blue, and violet colors. They are easily propagated by seeds, offsets, and cuttings of their stalks. The tender kinds require the common treatment of other exotics. They are natives of America, from which their seeds must be procured.

L. siphilitica grows in most places in Virginia, and stands our winter. The root is an article of the materia medica. It is perennial, has an erect stalk three or four feet high, blue flowers, a milky juice, and a rank smell. The root consists of white fibres about two inches long, resembles tobacco in taste, which remains on the tongue, and is apt to excite vomiting. It is used by the North American Indians as a specific for the venereal disease. The form is by decoction; the dose is gradually increased till it bring on very considerable purging, then intermitted for a little, and again used in a more moderate degree till the cure be completed. The ulcers are also washed with the decoction, and the Indians sprinkle them with the powder of the inner bark of the spruce tree. The same strictness of regimen is observed as during a salivation by a mercurial course.

LOBINEAU (Guy Alexis), a Benedictine monk born at Rennes, in 1666. He wrote several works of reputation; particularly, 1. *The History of Brittany*, 2 vols. folio. 2. *A continuation of Felibium's History of Paris*, 9 vols. folio. 3. *A History of Spain*. 4. *A Translation of Polybius*. He died in 1727, aged sixty-one.

LOBO (Jerome), a famous Portuguese Jesuit, born at Lisbon. He travelled into Ethiopia, as a missionary, and continued there for a long time. At his return he was made rector of the college of Coimbra, where he died in 1678. He wrote *An Historical Account of Abyssinia*, which is esteemed, and was translated into French by Le Grand, and into English by Dr. Johnson.

LOBSTER, *n. s.* Sax. *lobtcep*. A crustaceous fish.

Those that cast their shell, are the lobster, the crab and craw-fish. *Bacon's Natural History.*

LOBSTER. See CANCER.

LO'CAL, *adj.*

LOCAL'ITY, *n. s.*

LO'CALLY, *adv.*

LOCAT'ION, *n. s.*

Fr. *local*; Lat. *locus*. Pertaining to, or having the properties of, place; being in a particular place: locality is state or condition in relation to place: location, the act of placing or of occupying a particular place.

By ascending, after that the sharpness of death was overcome, he took the very local possession of glory, and that to the use of all that are his, even as himself before had witnessed, I go to prepare a place for you. *Hooker.*

How is the change of being sometimes here, sometimes there, made by local motion in vacuum, without a change in the body moved? *Digby on Bodies.*

Dream not of their fight,

As of a duel, or of the local wounds

Of head or heel. *Milton's Paradise Lost.*

That the soul and angels are devoid of quantity and dimension, and that they have nothing to do with grosser locality, is generally opinioned.

Glanville.

Whether things, in their natures so divers as body and spirit, which almost in nothing communicate, are not essentially divided, though not locally distant, I leave to the readers. *Id.*

To say that the soul is somewhere, means no more than it does exist; this, though a phrase borrowed from place, signifying only its existence, not location. *Locke.*

A higher flight the venturous goddess tries,
Leaving material world, and local skies. *Prior.*

Which fashions also and institutions themselves have grown out of the exigencies, the climate, situation, or local circumstances of the country. *Paley.*

Not that I mean to approve, or would enforce
A superstitious and monastic course:

Truth is not local, God alike pervades

And fills the world of traffic and the shades. *Cowper.*

In case of invasion, or appearance of an enemy in force upon the coast of any part of the united kingdom, his majesty may order the local militia to be embodied and marched to any part of Great Britain.

Local Militia Act.

LOCAL, in law, something fixed to the freehold, or to a certain place: thus, real actions are local, since they must be brought in the county where they lie: and local customs are those particular to certain countries and places.

LOCH, *n. s.* Scottish. A lake.

A lake or loch, that has no fresh water running into it, will turn into a stinking puddle.

Cheyne's Philosophical Principles.

LOCHABER, a district of Scotland, in Inverness-shire, bounded by Moydart on the west, Glengary on the north, Badenoch on the east, and Lorn on the south. It derives its name from the lake or loch Aber; and extends about twenty miles from east to west, and thirty from north to south. The country is barren, bleak, mountainous, and rugged. In one of the most barren parts of this country, near the mouth of the River Aber, in the centre between the West and North Highlands, stands Fort William, with the town of Maryburgh, built upon a navigable arm of the sea, near the foot of Ben Nevis. The inhabitants pay little attention to any commerce, but

that which consists in the sale of their black cattle; and hunt fowl and fish as the seasons permit, and as their occasions require.

LOCHES, a town of France, in the department of Indre and Loire, and late province of Touraine. It is defended by a strong castle, and was anciently famous, or rather infamous, for its horrid dungeons, built by Lewis XI; in one of which Lewis Storza, duke of Milan, after ten years' imprisonment, ended his days. It is seated on the Indre, fifteen miles south of Amboise, and twenty south-east of Tours. Long. 0° 51' E., lat. 47° 10' N.

LOCH-LEVEN, a spacious and beautiful lake of Kinross-shire, about fifteen miles in circumference and four in length, interspersed with islands of various appearance and extent. One of these, called St. Serf's Isle, contains forty-eight acres of good pasture. The ancient priory of Loch-Leven, founded by Brudus king of the Picts, was seated in it: two miles north of it lies a small island almost covered with the ruins of a castle, anciently belonging to the Douglasses of Loch-Leven, and afterwards used as a state prison. In this castle, the unfortunate Mary queen of Scots was kept a close prisoner, from June 16th, 1567, to May 2d, 1568. It is said to have been founded by Congal, the son of Dongart king of the Picts, and occasionally inhabited by king Alexander III. Its whole circuit is 585 feet. Patrick Graham archbishop of St. Andrew's, and grandson of king Robert III., died a prisoner here in 1468; and the earl of Northumberland was imprisoned in it from 1569 to the end of 1572. The island is ornamented with trees. The lake abounds with a great variety of different kinds of trouts, of a high flavor and bright red color. The lake also abounds with eels, pikes, perches, &c.; and the islands in it are frequented by herons, snipes, teal, swans, gulls, rails, king's fishers, &c.

LOCHMABEN, an ancient royal borough in Annandale; governed by a provost, three bailies, dean of guild, treasurer, and nine counsellors. Its first charter, granted by king Robert I., being destroyed with its records by the English, a new one was granted by James VI. in 1612. It has fairs in January, April, July, and October, and joins with Dumfries, Sanquhar, Annan, and Kirkcudbright, in sending a representative to the imperial parliament. It is almost surrounded with lakes, and is seated on the west side of the Annan, near its junction with the Ae and Kinnel; eight miles north-east of Dumfries, and twenty-two from Annan.

The site of a very ancient castle, close to the town, on a fine eminence, between the castle and Kirk Lochs, surrounded by a deep moat and fosse, is still visible. It was the original seat of the Bruces, lords of Annandale, and the birth-place of king Robert Bruce. The stones were carried away to build another castle, which is seated on a peninsula in the castle Loch, and was by far the largest and strongest of any either on the English or Scottish borders next to Carlisle, against which it was a frontier garrison. It occupies about an acre, and contains three courts, strongly built of stone and lime. The walls are twelve feet thick. It was surrounded with three

deep fosses, filled with water from the lake which met on each side. The whole fortification contains about thirteen acres. The inner foss went through the castle, within which there was a basin for the boats, to preserve them from the enemy and the weather. Before the Union, a garrison of 200 men was constantly kept in it. The castle Loch, on which it stands, is a beautiful lake on the south side of the town, one mile and a half long and one broad.

LOCK, *n. s., v. a., & v. n.* } Sax. loc, lucan; }
LOCK'ER, *n. s.* } Goth. lok, luka. A }
LOCK'ET, } fastening by way of
 clasp, bolt, or grapple; a quantity of hair or wool hanging together: hence any thing that stops or secures an opening; secures the priming of a gun, &c.: to lock is to fasten or shut with locks; hence to close or fasten any way; and, as a verb neuter, to become fast; to unite: a locker, and locket, things fastened by a lock or catch; also the catch or spring of such things.

Thine herte to me now woll I shet,

For all thy joyful *locke* and knet

I bind undir this little keie,

That no wight maie cary awaie.

Chaucer. Romaunt of the Rose.

His grisly *locks*, long growen and unbound,
 Disordered hung about his shoulders round.

Spenser.

No gate so strong, no *lock* so firm and fast,
 But with that piercing noise flew open quit or brast.

Id. Faerie Queene.

For not of wood, nor of enduring brass
 Doubly disparted it did *lock* and close,

That when it *locked*, none might through it pass.

Id.

We have *locks*, to safeguard necessities,
 And pretty traps to catch the petty thieves.

Shakspeare.

I am *locked* in one of them;

If you do love me, you will find me out. *Id.*

The bottom was set against a *lock* of wool, and the
 sound was quite deaded. *Bacon.*

Then seek to know those things which make us
 blest,

And, having found them, *lock* them in thy breast.

Denham.

They must be practised in all the *locks* and grips
 of wrestling, as need may often be in fight to tug
 or grapple, and to close. *Milton on Education.*

Where knights are kept in narrow lists,

With wooden *lockets* 'bout their wrists.

Hudibras.

A goodly cypress, who bowing her fair head over
 the water, it seemeth she looked into it, and dressed
 her green *locks* by that running river. *Sidney.*

Either they *lock* into each other, or slip one upon
 another's surface; as much of their surfaces touches
 as makes them cohere. *Boyle.*

The garden, seated on the level floor,

She left behind, and, *locking* every door,

Thought all secure.

Dryden.

Sergesthus, eager with his beak to press

Betwixt the rival galley and the rock,

Shuts up the unwieldy centaur in the *lock*. *Id.*

If one third of the money in trade were *locked* up,
 must not the landholders receive one third less?

Locke.

As there are *locks* for several purposes, so are there
 several inventions in *locks*, in contriving their wards
 or guards. *Moxon.*

A gun carries powder and bullets for seven charges
 and discharges: under the breach of the barrel is

one box for the powder; a little before the *lock* another for the bullets; behind the cock a charger, which carries the powder to the further end of the *lock*. *Grewe.*

A *lock* of hair will draw more than a cable rope. *Id.*

Behold the *locks* that are grown white
Beneath a helmet in your father's battles.

Addison.

I suppose this letter will find thee picking of daisies, or smelling to a *lock* of hay. *Id.*

I made *lockers* or drawers at the end of the boat. *Robinson Crusoe.*

Death blasts his bloom, and *locks* his frozen eyes. *Gay.*

Two *locks* that graceful hung behind
In equal curls, and well-conspired to deck,
With shining ringlets her smooth ivory neck. *Pope.*

Your wine *locked* up,
Plain milk will do the feat. *Id. Horace.*

Always *lock* up a cat in a closet where you keep your china plates, for fear the mice may steal in and break them. *Swift.*

Prudent men *lock* up their motives; letting familiars have a key to their heart, as to their garden. *Shenstone.*

Fleecy *locks* and black complexion
Cannot forfeit Nature's claim;
Skins may differ, but affection
Dwells in white and black the same. *Couper.*

LOCKS. Mechanical fastenings for doors were employed at a very early period, and we have seen some of those brought from Herculeaneum that might, in complexity, vie with the most curious productions of the present day. From the various structure of locks, accommodated to their different intentions, they acquire various names. Those placed on outer doors are called stock-locks; those on chamber doors, spring-locks, those on trunks, trunk-locks, padlocks, &c. The principal parts of the spring-lock are, the main-plate, the cover-plate, and the pin-hole: to the main-plate belong the key-hole, top-hook, cross-wards, bolt-toe or bolt knob, drawback-spring tumbler, pin of the tumbler, and the staples; to the cover-plate belong the pin main-ward, cross-ward, step-ward, or dap-ward; to the pin-hole belong the hook-ward, main cross-ward shank, the pot or bread, bow-ward, and bit.

The principle on which all locks depend is the application of a lever to an interior bolt, by means of a communication from without; so that by means of the latter, the lever acts upon the bolt, and moves it in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks, in general, therefore, depends on the number of impediments we can interpose betwixt the lever (the key) and the bolt which secures the door: and these impediments are well known by the name of wards, the number and intricacy of which alone are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lock-maker to open it without the key, and thus to elude the labor of the other.

The excellence of locks consists in the security they afford; and as numberless schemes are continually brought forward by designing men, to elude every contrivance of the most ingenious mechanics, the invention of a durable lock, so constructed as to render it impossible for any person to open it without its proper key, has ever been an object of considerable importance.

Denon has engraved an Egyptian lock of wood of very clumsy construction; and such were those of the Greeks and Romans, or at least some similar. Bars or bolts suspended by chains were drawn backwards or forwards by means of a hook or key, or raised out of a latch, and let fall, or a bolt coggled was caught in one of the teeth, and drawn back by the key. Sometimes there was a box with a pin, which box received a bar, that the pin (balanos) confined. A key in the form of a vice, called balanagra, disengaged the pin, and the bar fell or turned aside. But wooden locks still exist in the Highlands, so artfully contrived by notches, made at unequal distances, within side, that they can only be opened by the wooden key which belongs to them. These were probably Celtic, for locks and keys of metal are found in British towns occupied by the Romans. Before the use of keys and locks they fastened their doors with knots, according to fancy, which were very difficult to unloose, because the secret was known only to the makers. The locks upon scrinia resemble our trunk locks. Du Cange mentions the pessusulus versatilis, or turning latch, box-locks, chain-locks, or padlocks, as early at least as 1381; gate-locks; the speldolum or crook by which a chain was let into the lock, and the vertevella not easily defined. The lock and key of Taillebois Castle was vast and substantial, in the form of a fetter lock. The locks of our old church doors and chests familiarly show their construction. On opening a small ancient brass ring lock, the letters on each ring were thus placed together E, R, C, O. Nares mentions also a padlock formed of rings, marked with letters (Amen) which when placed to form the word would open, but not otherwise. This therefore is not a modern fashion. It seems that on chamber-doors there were often two locks; one called the privy-lock.

The marquis of Worcester furnishes the following curious suggestion for the escutcheon of a lock: 'An escutcheon, to be placed before any of these locks with these properties. 1. The owner, though a woman, may, with her delicate hand, vary the ways of coming to open the lock 10,000,000 of times, beyond the knowledge of the smith that made it, or of me who invented it. 2. If a stranger open it, it setteth an alarm a-going, which the stranger cannot stop from running out; and besides, though none should be within hearing, yet it catcheth his hand, as a trap doth a fox; and, though far from maiming him, yet it leaveth such a mark behind it as will discover him if suspected; the escutcheon or lock plainly showing what money he hath taken out of the box, to a farthing, and how many times opened since the owner had been at it.'

The noble author does not enter into any further particulars of his contrivance: but Mr. Par-

tungton, in his edition of the work, thus illustrates it:—‘The two principal properties of this escutcheon may be readily contrived; and the first of them has, in fact, been already applied to a very ingenious padlock, invented by Mr. Marshall, and for which the Society of Arts voted him a reward of ten guineas. In Mr. M.’s escutcheon the letters or figures commonly used in the ring padlock allow an almost endless variety of changes, and the owner may in one minute alter the arrangement in such a manner that even the maker would experience as much difficulty to open it, as an entire stranger to its construction. To render the combination of letters variable, the characters must not be engraved upon the outside of the rollers themselves, but upon a thin brass hoop made to fit on its outer surface; and a spring fastened to the roller, and pressing upon the inside of the hoop, will cause a sufficient degree of friction to make them move together.

‘The other part of this invention is equally simple with the preceding. An alarm, such as is attached to a clock, may easily be wound up prior to closing the box; and the lid provided with a chamfered bolt or staple, capable of effecting its discharge when the box is opened.

‘To register the amount of money taken from the box, it will be necessary either to place each distinct piece of money in separate divisions, or to put a number together in one deep recess capable of admitting but one piece to pass at a time. As the pieces are shaken out, they will, in their passage, raise a lever capable of moving a wheel one division in the passage of each piece. The Bank of England have a method somewhat similar for registering the number of notes worked from the printing press of that establishment.’

In the year 1784 the Society of Arts conferred their silver medal on Mr. Taylor, of Petworth, for his improvement on the latch or spring-bolts of common locks. This was effected by simply reversing the tumbler, so that its curved side acts against two stubs fixed on the tail of the latch, and thrusts back the latter with ease; whether the knob be turned to the right or the left, when the lock is opened. Mr. Taylor has also, behind the tail of the latch, fixed a guide containing a groove, in which runs a small friction-wheel, that serves to keep the latch in its direct situation, and at the same time to diminish its friction; the arms of its tumbler are somewhat contracted, in order that the latch or spring bolt may move with greater facility. By this construction the parts of the tumbler and latch, which are in contact, move in a line, so that they pass over the greatest space under the smallest angle; and the lock itself may be constantly used for several years, without requiring the application of oil.

Various patents have been obtained for the construction of locks, so as to prevent the possibility of picking them: the principal of these is Mr. Bramah’s, registered in 1784. One of Mr. Bramah’s simplest forms of a lock for a drawer, or for a door, is represented in plate *Locks*, figs. 1, 2, 3, and 4; in which *A* represents the bolt, fitted to slide on the metal plate *BBC*, by passing through a hole in the side *C*, which is turned

up; the other end of the bolt is guided by passing under proper grooves in the lower side of the circular box *DD*, which is screwed to the plate *B* to confine the bolt down. It contains the whole mechanism of the lock, consisting of an interior cylinder or barrel *EE*, shown in the section, fig. 3. This barrel is fitted to turn round within the box *DD*; the upper end *aa* being received into a cavity exactly fitting it, and the middle encompassed by a circular ring of steel plate *bb*, screwed into the box, as shown in fig. 3. The ring enters a circular groove formed round the barrel, and thus confines it from having any other motion than a rotation on its axis, and this only by the aid of the key *ll*, fig. 4. The barrel has a hole through its centre, which is closed at bottom by a circular plate screwed to it, and supporting the central pin *G*, which occupies the centre of the hole through the barrel; this centre pin guides the key in entering the lock. When the barrel *EE* is turned round by the key it shoots the bolt *A*, by an ingenious contrivance, explained in fig. 2, an aperture being cut through the plate *BC* to exhibit it. The plate *F*, on the lower end of the barrel *E*, has a pin *f* projecting from it: this pin enters a curved opening, at a small distance from the centre, and therefore describes a circle when the barrel is turned round, cut through the bolt *A*, as is shown by the dark curve *F* in fig. 2. In the position there shown the bolt is withdrawn, and the pin *f*, resting against the solid part of the groove, prevents the barrel being turned round any farther in the direction from *F* to *f*: but, by the application of the key, the barrel may be turned in the other direction, in which course it passes round in a circular part of the groove, and therefore produces no motion of the bolt *A*, until the pin *f* strikes the straight part *g* of the groove, and acts against it to throw the bolt forwards: and when the barrel has made a complete circuit, and the pin *f* is again come to the same position it was at first, the bolt is shot out as at fig. 1, and the pin is resting in the hollow *h*, which prevents its moving any further in the same direction. When the barrel is turned back again, the pin *f* acts against the notch *i*, and the curved part *k* of the groove, and withdraws the bolt into the position of fig. 2; now the pin *f*, either when the bolt is shot out or in, is in a right line with the centre of the barrel *E*, to which it is fixed, and the direction of the bolt’s motion. By this means no force whatever applied to drive back the bolt can have the least tendency to turn the barrel round, and strain the mechanism which prevents its motion, unless the parts are first put into a particular arrangement by the key.

The key has six notches cut in the end of it, and, being forced down into the key-hole *ll*, depresses all the sliders at once, until the projecting leaf *t* of the key stops upon the bottom of the recess cut in the upper edge of the barrel. In this position the sliders are depressed, so that the notch made in each slider comes exactly opposite the steel ring *bb*, and the barrel is at liberty to turn round all the sliders, being by this means removed, or at least relieved from the steel ring, which embraces a groove cut round the barrel, but which cannot turn round thereat

unless the sliders are also moved by the key, that the notches cut in them may coincide with the groove cut round the barrel, and then it can turn freely round. The key, having thus relieved the barrel by being thrust in as far as it can go, obtains a hold of the barrel to turn it round, by the leaf *t* entering the recess, which it exactly fills up, so as to form a continuation of the circular top of the barrel: but, as soon as the key is turned round with the barrel a small quantity, its leaf is caught beneath the circular cavity in the top of the box *D*; and thus the key is prevented from being thrown out by the spiral spring, until it has been turned quite round, and locked or unlocked the bolt: then the leaf of the key coming opposite the enlargement *z*, fig. 1, of the key-hole *H*, the spring throws the key out, and raises all the sliders, that they may interlock with the steel plate *bb*, and prevent the barrel from turning, unless the key be again put in (its leaf being opposite the aperture *z* of the key hole), and, being thrust forwards as far as it will go, the barrel will turn round very easily; and, when it has made a complete circuit, the lock is opened, and the key thrown out of the key-hole by the spring.

The security of this ingenious lock from being picked, or opened by a false key, depends upon a circumstance not yet mentioned, which is, that the notches in the six sliders are so made, that every one requires to be depressed a different quantity to bring them all at once opposite the steel ring, in which position alone the barrel can be moved. For this reason the six notches in the key are all of different depths, correspondent to the positions of the notches in their respective sliders; and, unless each notch in the key is of the proper depth, the lock cannot be opened; for any one being too deep, that slider will not be pressed low enough to relieve the barrel, and will hold it fast, though all the others may be correct: on the other hand, any notch not being of sufficient depth, the slider it acts upon will be pressed too far, and in this case the notch in it, having passed by the steel ring, will lock the barrel as effectually as though it was not far enough. Thus this lock admits of an immense number of combinations: 1st, in the number of the sliders; 2dly, in the depths of the different notches in the key; and, 3dly, the arrangement of these sliders. The combination of these three changes admits such an immense number of varieties of locks, that it never need happen that two locks should be made to open by the same key. Any of Mr. Bramah's locks may be arranged so as to require a new and different key in case the original should be lost or stolen: for this purpose the lock must be opened, and the sliders taken out and changed into different grooves: a new key must now be made, with the grooves of the same depth as the original key, but arranged in a different order, corresponding with the new arrangement of the sliders. The old key will not now open the lock.

To pick a lock of this kind is perhaps impossible; because, though the sliders are exposed to the examination of any person, yet no information can be obtained of the depth of each of the sliders required to be depressed; for, unless they

are all together pressed down, the barrel cannot be turned in the least, and, without turning it, no guess can be made by pressing down any one slider of the depth at which the notch in it will be opposite the steel ring. Another great advantage of these locks is, that from the circumstance before explained, of the bolt having no action to turn the barrel, though the barrel has a great power to shoot the bolt, a strong lock may have but a very small key. For instance, the bolt of the lock is of great strength, while the key *K* is so small, that it may always be carried suspended to the watch chain, and then it will not be in danger of being lost or mislaid, as one may happen to lose a key, and give opportunity for ill disposed persons to make a false key from it, unknown to the owner.

Mr. Bullock's drawback lock for house doors, &c., will next engage our attention. The improvement consists in latching the door; for it is well known, particularly in damp weather, that the air drawing through it rusts the head or bevel of the bolt, by which means it requires great force to shut the door, and occasions a disagreeable noise, besides shaking the building. It has frequently happened that the house has been exposed to robbers from the door being left unlatched, when supposed to be fast. This improvement removes all these inconveniences, as it lets the bolt shoot into the staple immediately when the door closes, but not before; and the reliever works so very easy, that the door is made fast with $\frac{1}{4}$ th part of the force required with locks upon the common construction.

Mr. Bullock's lock is represented in fig. 5, where *A* is the new iron latch here affixed to an old common drawback house-lock. *B*, an iron pin at one end of the latch, on which pin it is moveable. *C*, a projecting part of the latch, which, when the common spring bolt *D* of the lock is drawn back, in the usual manner, is forced into the nick on its higher part at *E*, by the spring *F* underneath the latch. The bolt *D* then remains within the lock, until, on closing the door, the reliever *G* gently presses on the lock box, fixed in the common way on the door cheek; which pressure draws the projecting part *C* out of the nick *E*, and permits the end of the bolt *D*, by the force of the spring *G*, to slide into the lock-box, and fasten the door.

A lock invented by Mr. Stansbury, an American gentleman, has great merit. To explain it, we must suppose that a flat circular plate is fitted to turn round upon the centre-pin for the key, and that this plate, when turned round, shoots the bolt, which may be done by various means. The locking part consists of four, six, or more small steel pins, which are received in holes made very near each other, through both the circular turning plate, and the fixed plate beneath it. By these pins the circular plate is held fast from turning. The key has the same number of pins, and arranged in the same position and distance, as the pins in the plate. The key, being introduced, is pressed forwards against the circular plate, and turned round till the pins in it come over the pins in the circular plate, and the pressure of the hand forces the pins out of the circular plate, the pins in the key

occupying the place of them. The plate is now relieved, and the key has hold of the plate to turn it round and open the lock. Each pin is provided with a spring behind the fixed plate to force it forwards. The difficulty of making a false key to this lock is very great; as any error in the number, size, position, or length of the pins, will prevent it from opening the lock. To avoid the danger of impressions being taken, many marks are stamped upon the circular plate, which are exactly the same as the marks of the real pins: thus an impression taken from it would only mislead.

Mr. Stainsbury has also made an ingenious improvement upon the common spring door-lock. The handle which opens the spring catch for fastening the door, instead of requiring to be turned round, is made so that it withdraws the spring catch, by pushing the handle on one side of the door and pulling it on the other. This method is extremely convenient; for pressing the handle releases the lock, and continuing the pressure opens the door, and pulling the handle on the other side has the same effect. A person with his hands full may open such a door by only leaning against the handle.

Mr. Nicholson has invented a secret lock of more than 6000 combinations; it possesses the following requisites:—1. That certain portions of the lock are variable in position through a great number of combinations, only one of which will allow the lock to be opened or shut. 2. This last combination is variable at the pleasure of the possessor. 3. It is not possible, after the lock is closed and the combination disturbed, for any one, not even the maker himself, to discover by any examination what may be the proper situation of the parts required to open it. 4. Trials of this nature will not injure the work. 5. It requires no key. And 6. It is as easily opened in the dark as in the light. This lock consists of four wheels: and by adding a fifth the combinations would be increased to nearly 60,000.

It is well known that, in the usual way of arranging the levers of locks, it is necessary that they should ascend to their proper places before the bolt can pass; which arrangement gives an opportunity of introducing a nail, or a piece of stout wire, &c., into the lock, and thus raising the levers without the necessity of using the key. In Mr. Somerford's lock, for which he was rewarded by the Society of Arts, the arrangement has been changed; one lever being made to ascend, and the others to descend, before the bolt can be shot. These works may be put into all kinds of locks without increasing their bulk, and the bolt may be made to take on one side of the lock or on the other. The lower ascending lever has an iron plate attached to it, the use of which, besides receiving the key and thus bringing it down to its central place, is, that it stands as a complete guard in front of the riding lever which descends. The lever on the top of the bolt is also of a new construction, having the lower levers working in its racks, and refusing to let them pass till it is brought to its proper situation.

Fig. 6 is a front view of the lock, the upper

plate being removed; *aa* the bolt, having a longitudinal perforation, in each side of which are four notches opposite each other; *bb* a plate of brass fixed to the bolt by the pin and collet *c*, under which it freely moves; this plate has a perforation with four notches in the upper side, and three in the under, corresponding with the notches in the bolt, but deeper; *dd* a spring fixed to the side of the bolt acting on the protuberance *b* of the plate *bb*, and pressing it on one side, so as to prevent the notched perforation corresponding with that in the bolt. To move the bolt, the key must by its hook *l*, fig. 7, travelling in the groove *m* of the under plate *f*, pull the pin just out of the upper notch, and no more, while the front of the key, pushing the second plate *e*, moves its pin just out of the bottom notch, and no more; and now, the pins being even, the bolt is free of them, but is locked by its upper plate *bb* catching them in two of its upper notches; therefore the upper front of the key must raise this plate to make its perforation coincide exactly with that in the bolt, and then it is free.

The improved mortise lock, contrived by Messrs. T. and S. Smith, of Darnick, is represented in fig. 8. *A* is the spring-bolt, cranked inside to avoid the key of the lock-bolt, and to bring its nose and tail into the same line. *B* the tumbler or follower, of hardened steel, made to work upon the beech *CC*, which is of brass, and fixed to the bell by the tenon, *DD*. *E* a piece of brass, with an oblong hole through it, to admit of the tail *F* working through it, to keep the bolt in its proper place, and diminish the friction. The spring *G*, and player *H*, are brought to the fore end of the lock, which allows it to be narrowed at the other end.

In the lock-bolt and night-bolt there is little difference from the common lock. The advantages of a lock constructed upon this plan are the following: viz.

1. It is less bulky than the common lock, easier put on, and does not weaken the door so much.

2. There is less friction in the the spring being placed to draw the bolt in, as in the common lock. The slide *at* *F* also contributes much to diminish the friction.

3. It works with perfect equality whichever way the handle is turned, from the tumbler being placed exactly in the line of the centre of the bolt; which it is evident the common lock can never do, from the tumbler being placed so far from the bolt. In the common lock there is a difference, in most cases, of between thirty and forty per cent. between the turns of the handle, which is the reason of the bolt coming readily back when the handle is turned the one way, and often sticking fast when turned the other way.

LOCKE (John), F. R. S., was the son of John Locke of Pensford in Somersetshire; was born at Wrington near Bristol in 1633; was sent to Christ Church in Oxford, and became acquainted with the works of Des Cartes which first attracted his attention to philosophy. He applied himself with vigor to his studies, particularly to physic, in which he gained a con-

siderable knowledge, though he never practised it. In 1694 he went to Germany as secretary to Sir William Swan, envoy from the English court to the elector of Brandenburg, and some other German princes. In 1695 he returned to Oxford, where he applied himself to natural philosophy, and became acquainted with lord Ashley, who introduced him to some of the most eminent persons of that age. In 1670 he began to form the plan of his *Essay on Human Understanding*. About this time he became F. R. S. In 1672 his patron, lord Ashley, now earl of Shaftesbury, and lord chancellor of England, appointed him secretary of the presentations. In 1673 he was made secretary to a commission of trade, worth £500 a year; but that commission was dissolved in 1674. The earl of Shaftesbury, after his discharge from the Tower, retired to Holland in 1682, and Mr. Locke followed his patron thither. He had not been absent from England a year, when he was accused of having written certain tracts against the government, which were afterwards discovered to have been written by another; and in November 1684 he was deprived of his place of student in Christ Church. In 1685 the English envoy at the Hague demanded him and eighty-three other persons to be delivered up by the States General, upon which he lay concealed till 1686; and during this time formed an acquaintance with Lamborch, Le Clerc, and some few other learned men at Amsterdam. In 1689 he returned to England in the fleet which brought over the princess of Orange. Being esteemed a sufferer for the principles of the revolution, he obtained the post of commissioner of appeals, worth £200, and was offered to be sent abroad as envoy at the court of the emperor, the elector of Brandenburg, or any other where he thought the air most suitable to him: but he waived all these, on account of the infirm state of his health; which led him to prefer an offer made by Sir Francis Masham and his lady, of an apartment in their country seat at Oates, in Essex, twenty-five miles from London. This place proved perfectly agreeable to him in every respect. He found in lady Masham a lady of a contemplative and studious turn, injured from her infancy to deep speculations in theology, metaphysics, and morality. In this family Mr. Locke lived with as much ease as if the whole house had been his own; and he had the additional satisfaction of seeing this lady bring up her only son exactly upon the plan which he had laid down for the best method of education. He was made a commissioner of trade and plantations in 1695, which engaged him in the immediate business of the state. With regard to the church, he published a treatise the same year, to promote the scheme which king William had much at heart, of a comprehension with the dissenters. This, however, drew him into a controversy: which was scarcely ended, when he entered into another, in defence of his essay, which continued till 1698: soon after which, the asthma increasing with his years, he became so infirm, that, in 1700, he resigned his seat at the board of trade, as he could no longer bear the air of London sufficiently for a regular attendance upon it. After this he con-

tinued constantly at Oates, where he employed the remaining years of his life entirely in the study of the Holy Scriptures. He died in 1704, aged seventy-three. Whoever is acquainted with the barbarous state of the philosophy of the human mind, when Mr. Locke paved the way to a clear notion of knowledge, will be able to appreciate this great man's abilities; and discover how

provements that have since been made. His *Discourses on Government*, *Letters on Toleration*, and his *Commentaries on some of St. Paul's Epistles*, are justly held in the highest esteem.

LOCK'RAM, *n. s.* From lock, twisted hair
A sort of coarse linen.

LOCOMOTION, *n. s.* } *Lat. locus, motus.*
LOCOMOTIVE, *adj.* } Power of changing place.

LOCOMOTION. The chief obstacles which oppose locomotion, or change of place, are gravity and friction, the last of which is, in most cases, a consequence of the first. Gravity confines all terrestrial bodies against the surface of the earth, with a force proportionate to the quantity of matter which composes them. Most kinds of mechanism, both natural and artificial, which assist locomotion, are arrangements for obviating the effects of gravity and friction. Animals that walk, obviate friction by substituting points of their bodies instead of large surfaces, and upon these points they turn, as upon centres, for the length of each step, raising themselves wholly or partly from the ground in successive arcs, instead of drawing themselves along the surface. As the feet move in separate lines, the body has also a lateral, vibratory motion. A man, in walking, puts down one foot before the other is raised, but not in running. Quadrupeds, in walking, have three feet upon the ground for most of the time; in trotting, only two. Animals which walk against gravity, as the common fly, the tree-toad, &c., support themselves by suction, using cavities on the under side of their feet, which they enlarge at pleasure, till the pressure of the atmosphere causes them to adhere. In other respects their locomotion is effected like that of other walking animals. Birds perform the motion of flying by striking the air with the broad surface of their wings in a downward and backward direction, thus propelling the body upward and forward. After each stroke, the wings are contracted, or slightly turned, to lessen their resistance to the atmosphere, then raised, and spread anew. The downward stroke also, being more sudden than the upward, is more resisted by the atmosphere. The tail of birds serves as a rudder to direct the course upward or downward. When a bird sails in the air without moving the wings, it is done in some cases by the velocity previously acquired, and an oblique direction of the wings upward; in others, by a gradual descent, with the wings slightly turned, in an oblique direction, downward. Fishes, in swimming forward, are propelled chiefly by strokes of the tail, the extremity of which, being bent into an oblique position, propels the body forward and laterally at the same time. The lateral motion is corrected

by the next stroke, in the opposite direction, while the forward course continues. The fins serve partly to assist in swimming, but chiefly to balance the body, or keep it upright; for, the centre of gravity being nearest the back, a fish turns over, when it is dead or disabled. Some other aquatic animals, as leeches, swim with a sinuous or undulating motion of the body, in which several parts at once are made to act obliquely against the water. Serpents, in like manner, advance by means of the winding or serpentine direction which they give to their bodies, and by which a succession of oblique forces are brought to act against the ground. Sir Everard Home is of opinion that serpents use their ribs in the manner of legs, and propel the body forwards by bringing the plates on the under surface of the body to act, successively, like feet against the ground. This he deduces from the anatomy of the animal, and from the movements which he perceived in suffering a large coluber to crawl over his hand. Some worms and larvæ of slow motion, extend a part of their body forwards, and draw up the rest to overtake it, some performing this motion in a direct line, others in curves. When land animals swim in water, they are supported, because their whole weight, with the lungs expanded with air, is less than that of an equal bulk of water. The head, however, or a part of it, must be kept above water, to enable the animal to breathe; and to effect this, and also to make progress in the water, the limbs are exerted, in successive impulses, against the fluid. Quadrupeds and birds swim with less effort than man, because the weight of the head, which is carried above water, is, in them, a smaller proportional part of the whole than it is in man. All animals are provided, by nature, with organs of locomotion best adapted to their structure and situation; and it is probable that no animal, man not being excepted, can exert his strength more advantageously by any other than the natural mode, in moving himself over the common surface of the ground. Thus walking cars, velocipedes, &c., although they may enable a man to increase his velocity, in favorable situations, for a short time, yet they actually require an increased expenditure of power, for the purpose of transporting the machine made use of, in addition to the weight of the body. When, however, a great additional load is to be transported with the body, a man, or animal, may derive much assistance from mechanical arrangements. For moving weights over the common ground, with its ordinary asperities and inequalities of substance and structure, no piece of inert mechanism is so favorably adapted as the wheel-carriage. It was introduced into use in very early ages. Wheels diminish friction, and also surmount obstacles or inequalities of the road, with more advantage than bodies of any other form, in their place, could do. The friction is diminished by transferring it from the surface of the ground to the centre of the wheel, or, rather, to the place of contact between the axletree and the box of the wheel; so that it is lessened by the mechanical advantage of the lever, in the proportion which the diameter of the axletree bears to the

diameter of the wheel. The rubbing surfaces, also, being kept polished and smeared with some unctuous substance, are in the best possible condition to resist friction. In like manner, the common obstacles that present themselves in the public roads, are surmounted by a wheel with peculiar facility. As soon as the wheel strikes against a stone or similar hard body, it is converted into a lever for lifting the load over the resisting object. If an obstacle eight or ten inches in height were presented to the body of a carriage unprovided with wheels, it would stop its progress, or subject it to such violence as would endanger its safety. But by the action of a wheel, the load is lifted, and its centre of gravity passes over in the direction of an easy arc, the obstacle furnishing the fulcrum on which the lever acts. Rollers placed under a heavy body diminish the friction in a greater degree than wheels, provided they are true spheres or cylinders, without any axis on which they are constrained to move; but a cylindrical roller occasions friction, whenever its path deviates in the least from a straight line. The mechanical advantages of a wheel are proportionate to its size, and the larger it is, the more effectually does it diminish the ordinary resistances. A large wheel will surmount stones and similar obstacles better than a small one, since the arm of the lever on which the force acts is longer, and the curve described by the centre of the load is the arc of a larger circle, and, of course, the ascent is more gradual and easy. In passing over holes, ruts, or excavations, also, a large wheel sinks less than a small one, and consequently occasions less jolting and expenditure of power. The wear also of large wheels is less than that of small ones, for if we suppose a wheel to be three feet in diameter, it will turn round twice, while one of six feet in diameter turns round once; so that its tire will come twice as often in contact with the ground, and its spokes will twice as often have to support the weight of the load. In practice, however, it is found necessary to confine the size of wheels within certain limits, partly because the materials used would make wheels of great size heavy and cumbersome, since the separate parts would necessarily be of large proportions to have the requisite strength, and partly because they would be disproportioned to the size of the animals employed in draught, and compel them to pull obliquely downwards, and therefore to expend a part of their force in acting against the ground.

LOCOMOTIVE ENGINE, is that which is calculated to produce locomotion, or motion from place to place. See STEAM ENGINE.

LOCRI, or LOCRI EPIZEPHYRII, in ancient geography, a town of the Brutii, on the Ionian Sea; a colony of the Locri Ozolæ (Strabo); or rather of the Epicnemidii, according to Virgil, who calls it Narycii Locri, from Naryx, a town of the Locri Epicnemidii. The epithet Epizephyrii is from its situation near the promontory Zephyrium. (Strabo.)

LOCRI, or LOCRENSSES, the people of Locri. They are said to have been the first who used a code of written laws, compiled by Zaleucus from the laws of the Cretans, Lacedæmonians, and the

Areopagitæ, adding an express penalty to each law, which was before discretionary, at the option of the judge. (Strabo.) Adultery was punished with the loss of both eyes. Zaleucus's own son being convicted of this crime, in order to maintain the authority of the law, and at the same time to pay some regard to the intercession of the people in favor of his son, Zaleucus suffered the loss of one eye, his son losing another. (Ælian, Val. Maximus.)

LOCRI, a country of Achaia, in Greece; twofold, and divided by mount Parnassus into

LOCRI CITERIOR, occupied by the Locri Ozole, or Zephyrii, i. e. Western Locri, contained between Ætolia and Phocis, beginning at Naupactum, and running in a narrow slip of land, scarcely 200 stadia, along the sea, to the borders of the Phocenses; and **LOCRI** ULTERIOR, which lay beyond Parnassus, running out towards Thermopylæ, and reaching to the Euripus of Eubœa; occupied by the Locrii Opuntii, who dwelt on the Eubœan Sea; and the Locri Epicnemidii, who occupied mount Cnemis (Strabo); and these two were the Eastern Locri.

LOCULAMENTA, and **LOCULI**, in botany, cells or pockets. The internal divisions of a capsule, or other dry seed-vessel. These cells contain the seeds, and differ in number in different plants.

LOCULUS is also sometimes used to express the minute divisions in some species of antheræ, which contain the fine impalpable powder, supposed by the sexualists to be the principal agent in the generation of plants.

LOCUS, **GEOMETRICUS**, a line by which a local or indeterminate problem is solved. Thus if a right line suffice for the construction of the equation, it is called locus ad rectum; if a circle, locus ad circulum; if a parabola, locus ad parabolam; if an ellipsis, locus ad ellipsin; and so of the rest of the conic sections.

LOCUST, *n. s.* Lat. *locusta*. A species of **GRYLUS**, which see.

To-morrow will I bring the locusts into thy coasts.

Exodus.

Nothing now is left him, but a bare fruitless earth to live upon, and that covered over with locusts.

Bp. Hall.

LOCUST, in zoology. See **GRYLUS**.

LOCUST, in botany. See **CERATONIA**.

LOCUST TREE. See **GLEDITSIA**, **HYMENÆA**, and **ROBINIA**.

LOCUTORIUM. The monks and other religious in monasteries, after they had dined in their common hall, had a withdrawing-room, where they met and talked together among themselves; which room, from that sociable use and conversation, they called locutorium (from loquor, to speak), as we call such a place in our houses parlour, from the French parler; and they had another room which was called locutorium forinsecum, where they might converse with laymen.

LODEVE, a town of France, on the Lergues, in the department of the Herault. Its streets are narrow, it has, however, flourishing manufactures of silk stuffs, cloth, hats, oil, and wine. It was the birth-place of cardinal Fleury. During the war it supplied a great part of the clothing

of the French army. Population 8000. Twenty-nine miles west of Montpellier.

LODGE, *v. a. v. n. & n. s.* Saxon, *logian*; **LODGEMENT**, Mæso-Goth. *log-*
LODGER, *gan*, to lay; Fr. *loger*. To place;

deposit for a time; lay flat; afford an abode; temporary or settled; to settle; fix: as a verb neuter, to reside; take up an abode for the night, or generally: a lodge is a small appendant abode: lodgement, collocation, disposition, or collection of things in a place: lodger, one who hires his lodging, or lives in hired rooms; one who resides in a particular place: lodging has the same temporary and general application as lodger.

Thy father is a man of war, and will not lodge with the people. *Samuel.*

Oh, that I had in the wilderness a lodging place of wayfaring man, that I might leave my people! *Jeremiah.*

My lords

And soldiers, stay and lodge by me this night.

Shakspeare.

Every house was proud to lodge a knight.

Dryden.

At night he came

To his known lodgings, and his country dame.

Id.

He lodged an arrow in a tender breast,
That had so often to his own been prest.

Addison.

LODGE (Thomas), M.D., an English physician and poet of the seventeenth century. He was educated at Oxford, but graduated at Avignon. He settled in London, and obtained great practice among the Roman Catholics, as he was of that communion. He wrote two plays; viz. Wounds of Civil War, a tragedy; and, A Looking-Glass for London, a tragi-comedy; and assisted R. Green in some others. He died in 1625.

LODGEMENT, in military affairs, a work made by the besiegers in some part of a fortification (after the besieged have been driven out), to maintain it, and be covered from the enemy's fire. When a lodgement is to be made on the glacis, covert-way, or in a breach, there must be a great provision made of fascines, sand-bags, gabions, wool-packs, &c., in the trenches; and, during the action, the pioneers, under the direction of an engineer, with fascines, sand-bags, &c., should be making the lodgement, in order to form a covering, while the grenadiers are storming the covert-way.

LODI, a province of Austrian Italy, in the government of Milan, surrounded by the grand duchy of Parma, and the delegations of Pavia, Milan, Bergamo, and Cremona. Its extent is 390 square miles. Pasturage is the chief object of agriculture; and it is in this district that Parmesan cheese is chiefly made. Population 141,000.

LODI, a considerable town of Austrian Italy, the capital of the above delegation, stands on the Adda, over which there is a wooden bridge of 600 feet in length. It is regularly and well built. One of its public squares contains a number of very superior buildings. The cath-

dral and convents claim the attention of the traveller: the most remarkable church is that called dell' Incononata, built by the celebrated Bramante, and painted partly in fresco, and partly in oil, by Callisto, a pupil of Titian. Here are manufactures both of silk and porcelain, and some considerable trade. Its chief export is the cheese made in the environs. Lodi is surrounded with walls, and stands high. Buonaparte's early military career was here distinguished, in 1796, by his forcing with the bayonet the passage of the bridge, though defended by 10,000 Austrians. Population 12,500. Sixteen miles north-east of Pavia, and seventeen south-east of Milan.

LODRONE, a town of Italy, in the bishopric of Trent, near which a bloody battle was fought, on the 12th of August, 1796, between the French and Austrians, wherein the latter were defeated. It is seated at the influx of the Chiese into Lake Idro.

LOEFFORT, an island of the North Sea, on the coast of Norway, a little north of the Maelstrom.

LOEVESTEIN, or LOWENSTEIN, a fortress of the Netherlands, in Guelderland, at the western point of the island of Bommelwaert, and eighteen miles E.S.E. of Rotterdam.

LOFFT (Capel), esq., barrister-at-law, was the son of Christopher Lofft, also a barrister, who resided in Carey Street, Fleet Street, where this his second son was born, in November, 1751. He distinguished himself at Eton, where he was placed in 1759, by several elegant compositions, and proceeded in 1769 to Peterhouse, Cambridge. Here he had the reputation of being a sound classical scholar; but his deficiency in mathematical knowledge lost him the Craven scholarship. His praise of Shakspeare in a Latin poem in hexameters, published as a tripot, March 1st, 1770, inspired Garrick with so great an interest in him, that to the exertions of that actor may be attributed the reconciliation, with some branches of his family, which eventually secured his succession to the Capel estates. He entered himself at Lincoln's Inn 1770, and, under the superintendence of his father, proceeded to qualify himself for the bar, to which he was called in Michaelmas term, 1755; having, in the mean time, published the Praises of Poetry; and Timoleon, a tragedy; both of which appeared in 1775. He also now commenced the study of the Hebrew and Saxon languages. He published in 1776 a collection of Cases, chiefly in the king's bench, from 1772 to 1774, with a Latin list of law maxims. The latter maxims he afterwards printed in an enlarged shape, in two volumes, under the title of Principia cum Juris Universalis tum præcipue Anglicani; with a translation, called Elements of Universal Law; about the same period he also wrote several political tracts on the subject of the American war. Succeeding to the Capel estates, in 1781, he removed to Troston, in Suffolk; and became an active magistrate for the county till 1800; when having unduly, as it was thought, exerted himself as under sheriff, to delay the execution of a young woman who had received sentence of death, Mr. Lofft was removed from the commis-

sion. In 1810 he became deputy recorder of Aldborough; but, conceiving that great facilities were afforded for the education of his family on the continent, he in 1816 proceeded to Brussels, and thence to Lausanne, Turin, and Montcallier; at which latter place he died, May 26th, 1824. Besides a variety of political pamphlets, Mr. Lofft was the author of Davideis, an imperfect poem in blank verse; Eudisia, a poem in blank verse, 1780; a Translation of the first two Georgics of Virgil, 1784; an Essay on the Law of Libel, 1785; an edition of Gilbert's Law of Evidence, with considerable additions, 2 vols. 8vo., 1792; Laura, or an Anthology of Sonnets, in 5 vols. 1814; and a volume of Aphorisms, from Shakspeare. He was a very considerable contributor also to most of the magazines of his day; and it was to his zealous patronage the public was, in a great measure, indebted for the publication of the Farmer's Boy, by Robert Bloomfield. Mr. Lofft married twice, and left a son and daughter by his first wife.

LOFODEN, a group of islands on the coast of Norway, lying between 67° 30' and 68° 45' of N. lat. They consist of five large and several smaller islands, having in all about 4000 inhabitants. Their lofty mountains are covered with perpetual snow. During the winter they are visited by boats, manned with perhaps 20,000 fishermen; and the value of the fish taken has been estimated at £12,000.

LOFT, *n. s.* From LIFT, which see.
LOFTY, *adj.* } A high or elevated place;
LOFTILY, *adv.* } the upper room or floor of
LOFTINESS, *n. s.* } a building. Lofty is high; towering, elevated in place, condition, true dignity or temper; proud.

Eutychus fell down from the third loft. *Acts.*
See lofty Lebanon his head advance,
See nodding forests on the mountains dance.

Pope.

Augustus and Tiberius had loftiness enough in their temper, and affected to make a sovereign figure. *Collier.*

They speak wickedly concerning oppression: they speak loftily. *Psaln lxxiii. 8.*

LOG, *n. s.* Sax. liggan, to lie.—
LOGGERHEAD, *n. s.* } Skinner. Goth. *log*,
LOGGERHEADED, *adj.* } *lag*. That which is laid
LOG'MAN, *n. s.* } or placed.—Thomson.
Belg. *logge*, heavy; lumpish. A mass of wood; a block; a dolt or blockhead. Loggerhead is also synonymous with blockhead. To go or fall to loggerheads, to scuffle; to bring two or more thick skulls into collision. Loggerheaded, stupid; thick-skulled; doltish. Logman, one who carries or transports logs from place to place.

Would the lightning had
Burnt up those logs that thou'rt enjoined to pile. *Shakspeare.*

For your sake
Am I this patient logman. *Id.*

Some log, perhaps upon the water swam,
An useless drift, which rudely cut within,
And hollowed, first a floating trough became,
And cross some riv'let passage did begin.

Dryden.
Says this loggerhead, what have we to do to quench
other people's fires? *L' Estrange.*

The ship still lay
Like a mere log, and baffled our intent.

Byron.

LOG, *n. s.* Heb. 17. The smallest measure of capacity among the Jews (about three-fourths of a pint).—Parkhurst. Arbutnot says the seventy-second part of the boll or ephah, and twelfth part of the hin.

A meat offering mingled with oil, and one log of oil.

Lev.

Log, in the Jewish antiquities, is mentioned (2 Kings vi. 25) as the fourth part of a cab. But in Leviticus the word log is often met with, and signifies that measure of oil which lepers were to offer at the temple after they were cured of their disease.

Log, a sea term, signifying a small piece of timber, of a triangular, sectoral, or quadrantal figure, on board a ship, generally about a quarter of an inch thick, and five or six inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed upon the arch, or circular side, so as to swim perpendicularly in the water, with about two-thirds immersed under the surface.

LOG AND LINE, or the LOG-LINE, a little cord, or line, about 150 fathoms long, fastened to the log by means of two legs, one of which passes through a hole at the corner, and is knotted on the opposite side, while the other leg is attached to the arch by a pin fixed into another hole, so as to draw out occasionally. By these legs the log is hung in equilibrio; and the line thus annexed to it is wound round a reel fixed for that purpose in the gallery of the ship. This line, from the distance of about ten, twelve, or fifteen fathoms off the log, has certain knots or divisions, which ought to be at least fifty feet from each other; though it was the common practice at sea not to have them above forty-two feet asunder. The length of each knot ought to be the same part of a sea-mile as half a minute is of an hour; and admitting the measurement of Mr. Norwood, who makes a degree on a great circle of the earth to contain 367,200 English feet, or about sixty-nine English statute miles and a half, and, therefore, one-sixtieth part of it, or a nautical mile, will be 6120 feet; $\frac{1}{60}$ th of 6120, or fifty-one feet, should be the length of each knot. But, because it is safer to have the reckoning rather before the ship than after it, therefore fifty feet may be taken as the proper length of each knot. The knots are sometimes made to consist only of forty-two feet each, even in the present practice; and this method of dividing the log-line was founded on the supposition that sixty miles, each of 5000 English feet, made a degree; for $\frac{1}{60}$ th of 5000 is forty-one and two-thirds, or, in round numbers, forty-two feet. Mariners, rather than quit the old way, though known to be erroneous, use glasses for half minute ones, that run but twenty-four or twenty-five seconds. They have also used a line of forty-five feet to thirty seconds, or a glass of twenty-eight seconds to forty-two feet. When this is the case, the distance between the knots should be corrected by the following proportion: as thirty is to fifty, so is the number of seconds of the glass to the distance between the knots upon the line. The heat or moisture of the weather

has often a considerable effect upon the glass, so as to make it run slower or faster; it should therefore be frequently tried by the pendulum in the following manner:—On a round-nail hang a string that has a musket-ball fixed to one end, carefully measuring between the centre of the ball and the string's loop over the peg thirty-nine inches and an eighth, being the length of a second pendulum; then swing it, and count one for every time it passes under the peg, beginning at the second time it passes; and the number of swings made during the time the glass is running out shows the seconds it contains. The line also is liable to relax and shrink, and should therefore be occasionally measured. The use of the log and line is to keep account, and make an estimate of the ship's way or distance run; which is done by observing the length of the line unwound in half a minute's time, told by a half-minute glass; for so many knots as run out in that time, so many miles the ship sails in an hour. Thus, if there be four knots veered out in half a minute, the ship is computed to run four miles an hour. No mention of this device for measuring the ship's way occurs till 1607, in an East India voyage published by Purchas; but from that time its name occurs in other voyages among his collections; and henceforward it became famous, being taken notice of both by our own authors and by foreigners; as by Gunter in 1623; Snellius in 1624; Metius in 1631; Oughtred in 1633; Herigone in 1634; Saltonstall in 1636; Norwood in 1637; Pournier in 1643; and by almost all the succeeding writers on navigation of every country.

LOG, HEAVING THE, is throwing it into the water on the lee-side, letting it run till it comes without the eddy of the ship's wake; then one, holding a half-minute glass, turns it up just at the first knot, or the mark from which the knots begin to be reckoned, turns off the reel, or passes over the stern. As soon as the glass is out the reel is stopped, and the knots run off are told, and their parts estimated. It is usual to heave the log once every hour in ships of war and East-Indiamen, and in all other vessels once in two hours; and if at any time of the watch the wind has increased or abated in the intervals, so as to affect the ship's velocity, the officer generally makes a suitable allowance for it at the close of the watch. The log is a very precarious way of computing, and must always be corrected by experience; there being a great deal of uncertainty in the yawing of the ship, going with the wind aft, or upon the quarter, in the heaving of it, by its coming home, or being drawn after the ship; on account of the friction of the reel and lightness of the log in the course of the current, and in the strength of the wind, which seldom keeps the same tenor for two hours together, which is the interval between the times for using the log in short voyages, though in longer ones they heave it every hour. Yet this is a much more exact way of computing than any other in use; much preferable certainly to that of the Spaniards and Portuguese, who guessed at the ship's way by the running of the froth or water by the ship's side; or to that of the Dutch, who used to heave a chip overboard, and to number the paces they

walk on the deck while the chip swims between any two marks or bulk-heads on the side.

LOG, THE COMPOUND. The above mentioned errors, and particularly the log's being subject to drive with the motion which the water may have at its surface, whereas the experiment requires it to be fixed in the place where it is when the mark commencing the knots goes off the reel, have been considered by writers, and many methods have been proposed to remove, or at least to lessen them. The late M. Bouguer proposed a method, which has been thought deserving of particular attention, in the *Mem. Acad. Sc.* 1747; afterwards in his *Treatise on Navigation*, published at Paris in 1753, and since reprinted in 1760, by the abbé de la Caille. For this purpose, take for the log a conical piece of wood, which fix to the log-line passed through or along its axis, at about forty, fifty, or sixty, or more feet, from one end; and to this end fix the diver, which is a body formed of two equal square pieces of tin, or of thin iron plate, fixed at right angles to one another along their diagonals; and its size so fitted to that of the cone that the whole may float. A cone of three inches diameter in the base, and of six inches in the slant height, is proposed by M. Bouguer to suit a diver made of plates about nine inches and three quarters square; the intersection of the diagonals is joined to the log-line, and the loop and peg fixed as in the common log. However, it has been found, that no kind of wood used in British dock-yards, when formed into a cone of the above dimensions, will float a diver made of stout tin plates, one side of the square being nine inches and three quarters. Such a diver, weighing one pound fourteen ounces avoirdupois, required to float it a cone of five inches diameter and twelve inches on the slant side, so as the point of the cone, which was made of light fir, should just appear above the water. Now supposing one side of such a square tin diver to be about ten inches, and made of plates only two-thirds of the thickness of the former, such a diver would weigh, with its solder, about twenty ounces, and can be floated by a light fir cone of four inches diameter in the base, and ten inches in the slant height or length; and such a compound log might perhaps be found on trial to be affected by about as much again as that proposed by M. Bouguer; and consequently the difference between the numbers given by the common log and compound log, must be augmented by two-thirds of itself for the necessary correction, as below. When the compound log of Bouguer, above described, is hove overboard, the diver will sink too deep to be much affected by the current or motion of water at the surface, and the log will thereby keep more steadily in the place where it first fell; and consequently the knots run off the reel will show more accurately the ship's rate of sailing. As the common log is affected by the whole motion of the current, so this compound log will feel only a part thereof, viz. such a part nearly as the resistance of the cone is to the resistance of the diver; then the resistances of the above cone and diver are about as one to five; and consequently this log will drive but one-fifth part of what the common

log would do; and so the ship's true run will be affected by one-fifth only of the motion of the waters. To obtain the true rate of sailing, it will be proper to heave alternately, hour and hour, the common log and this compound log; then the difference of their knots run off, augmented by its fourth part, is the correction; which, applied to the knots of the common log, will give the ship's true rate of sailing at the middle time between the hours when these logs were hove. The correction is additive when the compound log's run is the greatest, otherwise it is subtractive. To find the course made good: increase the observed angle between the log-lines by one fourth part; and this gives the correction to be applied to the apparent course, or the opposite of that shown by the common log; the correction is to be applied to the right of the apparent course, when the bearing of the common log is to the left of the compound log; and vice versa, to the left, when the bearing is to the right of it. Or thus: the lengths run off both logs, together with their bearings, being known; in a card or compass apply the knots run off, taken from a scale of equal parts, along their respective bearings, from the centre; join the ends; and in this line produced, on the side next the compound log's length, take one-fourth of the interval; then a line drawn from the end, thus produced, to the centre of the card, will show the true course and distance made good. When a current, such as a tide, runs to any depth, the velocity of that current may be much better ascertained by the compound log than by the common one, provided the diver does not descend lower than the run of the current; for, as those ships which are deepest immersed drive fastest with the tide, so the diver, by being acted on below, as well as the log on the surface, their joint motion will give the total effect of the current's motion better than could be had from the motion at the surface only. Also, by such a compound log, the depth to which any current runs may be easily tried.

We have an account, in the *Voyage to the North pole*, p. 97, of two other logs, which were tried by captain Phipps; one invented by Mr. Russel, the other by Foxon; both constructed upon this principle, that a spiral, in proceeding its own length in the direction of its axis through a resisting medium, makes one revolution round the axis; if, therefore, the revolutions of that spiral are registered, the number of times it has gone its own length through the water will be known. In both these the motion of the spiral in the water is communicated to the clock-work within-board, by means of a small line fastened at one end to the spiral, which tows it after the ship, and at the other to a spindle, which sets the clock work in motion. That invented by Mr. Russel has a half spiral of two threads, made of copper, and a small dial with clock-work, to register the number of turns of the spiral. The other log has a whole spiral of wood with one thread, and a larger piece of clock-work with three dials, two of them to mark the distance, and the other divided into knots and fathoms, to show the rate by the half-minute glass, for the convenience of comparing it with the log. This kind of log

will have the advantage of every other in smooth water and moderate weather; and it will be useful in finding the trim of a ship when alone, in surveying a coast in a single ship, or in measuring distances in a boat between head-lands and shoals: but it is subject to other inconveniences, which will not render it a proper substitute for the common log. See NAVIGATION.

* LOGAN, a chief among the Mingo tribe of the North American Indians, whose pathetic address to lord Dunmore, governor of Virginia, has been much and justly admired. The occasion was as follows; and the authenticity of the narrative is unquestionable. In spring, 1774, a robbery and murder were committed on an inhabitant of the frontiers of Virginia by two Indians of the Shawnee tribe. The neighbouring whites, according to custom, undertook to punish this outrage in a summary way. Colonel Cresap, a man infamous for the many murders he had committed on that much-injured people, collected a party, and proceeded down the Kanhaway in quest of vengeance. Unfortunately a canoe of women and children, with one man only, was seen coming from the opposite shore, unarmed, and unsuspecting any hostile attack from the whites. Cresap and his party concealed themselves on the bank of the river; and, the moment the canoe reached the shore, singled out their objects, and at one fire killed every person in it. This happened to be the family of Logan, who had long been distinguished as a friend of the whites. This unworthy return provoked his vengeance. He accordingly signalled himself in a war which ensued. In autumn, 1774, a decisive battle was fought at the mouth of the Great Kanhaway, between the collected forces of the Shawanees, Mingoes, and Delawares, and a detachment of the Virginia militia. The Indians were defeated, and sued for peace. Logan disdained to be seen among the suppliants; but, lest the sincerity of a treaty should be distrusted, from which so distinguished a chief absented himself, he sent by a messenger the following speech, to be delivered to lord Dunmore: 'I appeal to any white man to say if ever he entered Logan's cabin hungry, and he gave him not meat; if ever he came cold and naked, and he clothed him not. During the course of the last long and bloody war Logan remained idle in his cabin, an advocate for peace. Such was my love for the whites, that my countrymen pointed as they passed, and said, Logan is the friend of white men. I had even thought to have lived with you, but for the injuries of one man. Colonel Cresap, the last spring, in cold blood, and unprovoked, murdered all the relations of Logan, not sparing even my women and children. There runs not a drop of my blood in the veins of any living creature. This called on me for revenge. I have sought it; I have killed many; I have fully glutted my vengeance. For my country, I rejoice at the beams of peace; but do not harbour a thought that mine is the joy of fear. Logan never felt fear. He will not turn on his heel to save his life. Who is there to mourn for Logan? Not one.'

LOGAN (John), D. D., late a clergyman of the church of Scotland, author of several works of

merit. He was born in Mid Lothian about 1748; studied divinity at the university of Edinburgh, and was ordained minister of South Leith, in 1770. In 1781 he published his Philosophy of History, the substance of which had been delivered in his public lectures at Edinburgh, with great approbation. He also published his Poems, which underwent a second edition in 1782. In 1783 he wrote Runnemed, a tragedy, which he offered to the manager of Covent-garden theatre; but as the lord chamberlain did not approve of the political sentiments displayed in it, a license was refused, though it was afterwards acted at Edinburgh with much applause. His last work was A Review of the Principal Charges against Mr Hastings. Mr. Logan died in London in 1788. Two volumes of his Sermons were published after his death.

LOGARITHMIC LINES. For many mechanical purposes it is convenient to have the logarithms of numbers laid down on scales, as well as the logarithmic sines and tangents; by which means computations may be carried on by mere mensuration with compasses. Lines of this kind are always put on the common Gunter's scale; but as these instruments must be extended to a very great length, in order to contain any considerable quantity of numbers, it becomes an object of importance to shorten them. Such an improvement has been made by Mr. William Nicholson, and published in the seventy-seventh volume of the Philosophical Transactions. The principles on which the construction of his instruments depends are as follow: I. If two geometrical series of numbers, having the same common ratio, be placed in order with the terms opposite to each other, the ratio between any term in one series and its opposite in the other will be constant: Thus,

	2	6	18	54	162, &c.
	3	9	27	81	243, &c. Then,
2	3	6	9	18	27 54 81 162 243, &c.

where it is evident that each of the terms in the upper series is exactly two-thirds of the corresponding one in the lower. II. The ratio of any two terms in one series will be the same with that between those which have an equal distance in the other. III. In all such geometrical series as have the same ratio the property above mentioned takes place, though we compare the terms of any series with those of another: Thus,

{	2	4	8	16	32	64, &c.
{	3	6	12	24	48	96, &c.
{	4	8	16	32	64	128, &c.
{	5	10	20	40	80	160, &c.

where it is plain that 2, 4, 3, 6; also 2, 4, 4, 8, and 2, 4, 5, 10, &c., have the same ratio with that of each series. IV. If the differences of the logarithms of the numbers be laid in order upon equidistant parallel right lines, in such a manner that a right line drawn across the whole shall intersect it at divisions denoting numbers in geometrical progression; then, from the condition of the arrangement, and the property of this logarithmic line, it follows, 1st, That every right line so drawn will, by its intersections, indicate a geometrical series of numbers; 2dly,

That such series as are indicated by these right lines will have the same common ratio; and, 3dly, That the series thus indicated by two parallel right lines, supposed to move laterally, without changing either their mutual distance or parallelism to themselves, will have each the same ratio; and in all series indicated by such two lines, the ratio between an antecedent and consequent, the former taken upon one line, and the latter upon another, will be also the same. The first of these propositions is proved in the following manner:—Let the lines AB , CD , EF , plate LOGARITHMS, fig. 5, represent parts of the logarithmic line, arranged according to the proportion already mentioned; and let GH be a right line passing through the points c , e , a , denoting numbers in geometrical progression; then will any other line IK , drawn across the arrangement, likewise pass through three points f , d , b , in geometrical progression. From one of the points of intersection f , in the last mentioned line IK , draw the line fg parallel to GH , and intersecting the arrangement in the points i , h ; and the ratios of the numbers e , f , c , i , will be equal, as well as of a , h : because the intervals on the logarithmic line, or differences of the logarithms of those numbers, are equal. Again, the point f , the line id , and the line hb , are in arithmetical progression, denoting the differences between the logarithms of the numbers themselves; whence the quotients of the numbers are in geometrical progression. The second proposition is proved in a similar manner. For as it was shown that the line fg , parallel to GH , passes through points of division denoting numbers in the same continued ratio as those indicated by the line GH ; it may also be shown that the line LM , parallel to any other line IK , will pass through a series of points denoting numbers which have the same continued ratio with those indicated by the line IK , to which it is parallel. The third proposition arises from the parallelism of the lines to their former situation; by which means they indicate numbers in a geometrical series, having the same common ratio as before: their distance on the logarithmic line also remains unchanged; whence the differences between the logarithms of the opposite numbers, and of consequence their ratios, will always be constant. V. Supposing now an antecedent and consequent to be given, in any geometrical series, it will always be possible to find them, provided the line be of unlimited length. Drawing two parallel lines, then, through each of the numbers, and supposing the lines to move without changing their direction or parallel situation, they will continually describe new antecedents and consequents in the same geometrical series as before. VI. Though the logarithmic line contain no greater range of numbers than from 1 to 10, it will not be found necessary for the purposes of computation to repeat it. The only thing requisite is to have a slider or beam with two fixed points at the distance of the interval betwixt 1 and 10, and let a moveable point be made to range betwixt them always to indicate the antecedent; then, if the consequent fixed point fall without the rule, the other fixed point will always denote the division on which it

would have fallen had the ruler been prolonged; and this contrivance may easily be adapted to any arrangement of parallel lines whatever. The arrangement of right lines, however, ought always to be disposed in such a manner as to occupy a right angled parallelogram, or the cross line already mentioned ought always to be at right angles to the length of the ruler. Fig. 6 is a ruler consisting of ten parallel lines. Fig. 7 a beam compass for measuring the intervals. B , A , C , are the parts which apply to the surface of the ruler; the middle one, A , being moveable sideways in a groove in the piece DE , so as always to preserve its parallelism to the external pieces D , C , which are fixed at a distance equal to the length of the ruler, and have their edges placed in such a manner as to form, with the parallel lines which they intersect, a ratio, which by composition is one-tenth; which in the present case requires them to be at right angles to the length. The piece DE is applied to the edge FG of the ruler. The edges or borders H , I , K , L , are more conveniently made of transparent horn, or tortoise-shell, than of any opaque matter. In using this ruler, apply the edge of either B or C to the consequent, and slide the piece A to the antecedent; observing the difference between the numbers on the pieces denoting the lines they are found on: then, applying the same edge of A to any other antecedent, the other piece B or C will intersect a consequent in the same ratio upon that line, having the same situation with regard to the antecedent that the line of the former consequent had to its antecedent. But if B be the consequent piece, and fall without the ruler, the piece C will show the consequent one line lower; or if C , in like manner, fall without the ruler, then B will show the consequent one line higher. 'It might be convenient,' says Mr. Nicholson, 'for the purpose of computation, to make instruments of this kind with 100 or more lines: but, in the present instrument, the numbers on the pieces will answer the same purpose; for, if a consequent fall upon a line at any given number of intervals without the ruler, it will be found on that line of the arrangement which occupies the same number of intervals, reckoned inwards from the opposite edge of the ruler.' Fig. 8 is an instrument on the plan of a Gunter's scale, of twenty-eight inches and a half long, invented by the late Mr. Robertson. There is a moveable piece AB in the slider GH , across which is drawn a fine line: the slider having also lines CD , EF , drawn across it at distances from each other equal to the length of the ruler AB . In using the instrument, the line CD or EF is to be placed at the consequent, and the line in AB at the antecedent: then, if the piece AB be placed at any other antecedent, the same line CD or EF will indicate its consequent in the same ratio taken the same way: that is, if the antecedent and consequent lie on the same side of the slider, all other antecedents and consequents in that ratio will be in the same manner; and the contrary if they do not. But, if the consequent line fall without the ruler, the other fixed line on the slider will show the consequent, but on the contrary side of the slider to that where it would else have been seen by means of

the first consequent line. Fig. 9 is a circular instrument equivalent to the former; consisting of three concentric circles engraved and graduated upon a plate of an inch and a half diameter. Two legs, A and B, proceed from the centre, having right-lined edges in the direction of radii; and are moveable either singly or together. In using the instrument, place one of the edges at the antecedent and the other at the consequent, and fix them at the angle. Move the two legs then together; and, having placed the antecedent leg at any other number, the other will give the consequent one in the like position on the lines. If the line C D happen to lie between the legs, and B be the consequent leg, the number sought will be found one line farther from the centre than it would otherwise have been: and, on the contrary, it will be found one line nearer in the like case, if A be the consequent leg. 'This instrument,' says Mr. Nicholson, 'differing from that represented fig. 6, only in its circular form and the advantages resulting from that form, the lines must be taken to succeed each other in the same manner laterally; so that numbers which

fall either within or without the arrangement of circles will be found on such lines of the arrangement as would have occupied the vacant places, if the succession of lines had been indefinitely repeated sidewise. I approve of this construction, as superior to every other which has yet occurred to me, not only in point of convenience, but likewise in the probability of being better executed; because small arcs may be graduated with very great accuracy, by divisions transferred from a larger original. The instrument, fig. 6, may be contained conveniently in a circle of about four inches and a half diameter. The circular instrument is a combination of the Gunter's line and the sector, with the improvements here pointed out. The property of the sector may be useful in magnifying the differences of the logarithms in the upper part of the line of sines, the middle of the tangents, and the beginning of the versed sines. It is even possible, as mathematicians will easily conceive, to draw spirals, on which graduations of parts, every where equal to each other, will show the ratios of those lines by moveable radii, similar to those in this instrument.'

LOGARITHMS.

GENERAL DEFINITION.

1. LOGARITHMS. (logarithme, Fr. *λογος αριθμος*)—Logarithms, which are the indexes of the ratios of numbers one to another, were first invented by Napier lord Merchiston, a Scottish baron, and afterwards completed by Mr. Briggs, Savilian professor at Oxford. They are a series of artificial numbers, contrived for expediting calculations; and proceed in an arithmetical proportion, as the numbers they answer to do in a geometrical one. The addition and subtraction of logarithms answer to the multiplication and division of the numbers they correspond with; and this saves an infinite deal of trouble. In like manner will the extraction of roots be performed, by bisecting the logarithms of any numbers for the square root, and trisecting them for the cube, and so on. *Harris*.

The doctrine of logarithms being of great importance, in the science of mathematics, we shall explain their nature and properties more fully in the following section:—

SECT. I.—OF THE NATURE AND PROPERTIES OF LOGARITHMS.

2. Let there be two series of numbers, the one constituting an arithmetical progression, and the other a geometrical progression, as follows:—

Arith. prog. 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, &c.
Geom. prog. 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, &c.
where the terms stand over each other in such a manner, that 0 in the arithmetical series corresponds to unity in the geometrical series; then we readily perceive, that the two series, so arranged, possess the following properties:

3. 1. Let the sum of any two terms of the arithmetical series be taken; and also the product of the corresponding terms of the geometrical series; then, below that term of the arithmetical series, which is equal to the sum, will be

found a term of the geometrical series equal to the product.

Thus, if the terms of the arithmetical series be 3 and 5, those of the geometrical series will be 8 and 32. Now $3 + 5 = 8$; and $8 \times 32 = 256$; and, by inspecting the two series, we find that the term 256 in the geometrical series stands below 8 of the arithmetical series.

4. II. Let the difference of any two terms of the arithmetical series be taken, and also the quotient of the corresponding terms of the geometrical series; then, below that term of the arithmetical series which is equal to the difference, will be found a term of the geometrical series equal to the quotient.

Thus, if the terms of the arithmetical series be 5 and 8, and therefore those of the geometrical series 32 and 256; we shall have $8 - 5 = 3$, and $256 \div 32 = 8$; and we find, by inspecting the series, that 8 of the geometrical series stands below 3 of the arithmetical series. This last property is evidently nothing else than the converse of the former.

5. In the preceding geometrical series the common ratio is 2, but it may be any other number whatever, whole or fractional. Thus the same properties will be found to hold true of these series:

Arith. prog. 0, 1, 2, 3, 4, 5, 6, 7, &c.
Geom. prog. 1, 3, 9, 27, 81, 243, 729, 2187, &c.
where the common ratio of the geometrical series is 3. They also hold true in the following:—

Arith. prog. 0, 1, 2, 3, 4, 5, &c.
Geom. prog. 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$, &c.
where the common ratio is $\frac{1}{2}$.

6. To demonstrate that the two foregoing properties must necessarily be true in every case, it is only necessary to write down a geometrical series, according to the algebraic method of notation, thus, r^0 or 1, r^1 , r^2 , r^3 , r^4 , r^5 , r^6 , &c., where r denotes the ratio of the series, and it

presently appears, that the arithmetical series is supplied by the numeral exponents of the terms. Hence it follows, that the properties, which we have ascribed to any geometrical, and its corresponding arithmetical series, are no other than two well known propositions in algebra; namely, that the sum of the exponents of any two powers of an algebraic quantity is equal to the exponent of their product; and that the difference of their exponents is equal to the exponent of their quotient.

7. When the terms of an arithmetical progression are adapted to those of a geometrical progression, as in the three examples given in § 2 and 5, the terms of the arithmetical series are called the logarithms of the corresponding terms of the geometrical series.

Thus, in the first example, 0, 1, 2, 3, &c., are the logarithms of 1, 2, 4, 8, 16, &c., respectively.

In the second example, 0, 1, 2, 3, &c., are the logarithms of the numbers 1, 3, 9, 27, &c.

And, in the third example, 0, 1, 2, 3, &c., are the logarithms of 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, &c.

By applying now the properties of these series which were demonstrated in § 6, to logarithms, and their corresponding numbers, we may define logarithms to be a series of numbers in arithmetical progression, so adapted to another series of numbers in geometrical progression, that the sums and differences of the former correspond to and show the products and quotients of the latter.

8. From this definition of logarithms it appears, that there may be an infinity of different systems according as one or other geometrical series is adapted to the arithmetical series, 0, 1, 2, 3, &c. It may, however, be readily supposed that some systems are better suited to general calculation than others. Accordingly it has been found convenient in practice to adopt that in which the logarithm of 10 is unity: the series of numbers which may have their logarithms expressed by integers being as in the following table:—

Logarithms	0,	1,	2,	3,	4,	&c.
Numbers	1,	10,	100,	1000,	10,000,	&c.

9. With respect to the numbers between 1 and 10, 10 and 100, &c., and their corresponding logarithms, they may be understood to be supplied by interpolation, thus: Conceive a great number of geometrical proportionals to be inserted between the natural numbers 1 and 10 which are the extremes; also an equal number of arithmetical proportionals between their logarithms 0 and 1: then, if the number of geometrical proportionals be sufficiently great, some one or other of them will be sufficiently near to each of the natural numbers 2, 3, 4, 5, &c., to 9, as to admit of the one being taken for the other, without any sensible error. There will also be a corresponding logarithm to each, which, as it will be less than unity, may be most conveniently expressed by a decimal fraction.

10. Let us suppose the number of geometrical proportionals between 1 and 10, and also the number of arithmetical proportionals between 0 and 1, to be 9999, and therefore the number of terms, including 1 and 10, 10001. Then the 3011th term of the geometrical series will be

1·9999, or 2 nearly, and the corresponding term of the arithmetical series, ·3010, therefore the logarithm of 2 is ·3010, nearly. Again, the 4772d term of the geometrical series will be 2·9999, or 3 nearly; and the corresponding term of the arithmetical series ·4771; therefore the logarithm of 3 is ·4771 nearly; and so on with respect to other numbers.

11. If we suppose the series of natural numbers 1, 2, 3, 4, 5, &c., to be arranged in a table, so that each number may stand opposite to its corresponding logarithm; it is evident from the properties which we have shown to belong to logarithms, that, by means of such a table, the arithmetical operations of multiplication, division, involution, and evolution, may be performed with great facility.

12. For, since the sum of the logarithms of any two numbers is equal to the logarithm of their product, § 3, the product of any two numbers will be found in the table opposite to that logarithm which is the sum of the logarithms of the numbers.

Again, because the difference of the logarithms of two numbers is equal to the logarithm of the quotient arising from the division of the one number by the other, § 4, that quotient will be found in the table, opposite to the logarithm which is excess of the logarithm of the dividend, above that of the divisor.

13. Involution is performed by multiplying the root into itself a number of times, which is one less than the exponent of the power; therefore, if the logarithm of the root be multiplied by the exponent of that power, the product will be the logarithm of the power of the root. And, evolution being the reverse of involution, the logarithm of any root of a number will be had if we divide the logarithm of that number by the index of the root; and thence the root itself may be found, by inspecting the table of logarithms.

14. Upon the whole, therefore, it appears that by means of a table containing the series of natural numbers, 1, 2, 3, &c., as far as may be convenient, and their corresponding logarithms, the operations of multiplication and division may be reduced to the more simple operations of addition and subtraction; and the operations of involution and evolution, to those of multiplication and division.

SECT. II.—HISTORY OF LOGARITHMS.

15. The properties of a geometrical series, which constitute the foundation of the doctrine of logarithms, appear to have been known as far back as the days of Archimedes; for that celebrated mathematician makes use of them in his work entitled *Arenarius*, or *Treatise on the Number of Sands*. The same properties are also mentioned in the writings of Stifelius, a German mathematician, who lived about the middle of the sixteenth century. It does not, however, appear, that any person perceived all the advantages which might be derived from these properties, till about the beginning of the seventeenth century, when their utility was rendered evident by the happy invention of logarithms.

16. This discovery, certainly one of the most valuable that ever was made in mathematics, is

due to John Napier, baron of Merchiston, in Scotland, who published it to the world, in 1614, in a work which he called *Mirifici Logarithmorum Canonis Descriptio*, and which contained a large table of logarithms, together with their description and uses: but the author reserved his method of constructing them, till the sense of the learned concerning his invention should be known.

17. In the above mentioned work, Napier explains his notion of logarithms by lines described, or generated, by the motion of points, in this manner:—He first conceives a line to be generated by the motion of a point, which passes over equal portions of it, in equal small moments or portions of time. He then considers another line to be generated by the unequal motion of a point, in such a manner, that, in the aforesaid equal portions, or moments of time, there may be described, or cut off from a given line, parts which shall be continually in the same proportion with the respective remainders of that line, which had before been left; then are the several lengths of the first line the logarithms of the corresponding parts of the latter. Which description of them is similar to that which we have already given, viz. that logarithms are a series of quantities, or numbers in arithmetical progression, adapted to another series in geometrical progression.

18. Napier made the first, or whole length of the line, which is diminished in geometrical progression, the radius of a circle; and its logarithm 0, or nothing, representing the beginning of the first or arithmetical line. Thus the several proportional remainders of the geometrical line are the natural sines of all arches of a quadrant, decreasing down to 0; while the successive increasing values of the arithmetical line are the corresponding logarithms of those decreasing sines: so that, while the natural sines decrease from radius to 0, their logarithms increase from 0 to infinity. Napier made the logarithm of radius to be 0, that he might save the trouble of adding and subtracting it in trigonometrical operations, in which it so frequently occurred; and he made the logarithms of the sines, from the entire quadrant down to 0, to increase, that they might be positive, and so, in his opinion, easier to manage; the sines being of more frequent use than the tangents and secants, of which the whole of the latter, and the half of the former, being greater than radius, would, according to his construction, have their logarithms negative.

19. The description and use of Napier's canon being in the Latin language, they were translated into English by Mr. Edward Wright, the ingenious inventor of what is commonly, though erroneously, called Mercator's sailing. The translation was sent to the author, who revised it, and returned it with his approbation. Mr. Wright, however, dying soon after he received it back, the work, together with the tables, was published in 1616, after his death, by his son Samuel Wright, who dedicated it to the East India Company. It contained also a preface by Henry Briggs, of whom we shall have occasion to speak again presently, on account of the great share he bore in perfecting the logarithms.

20. As Napier's canon contained only the

natural sines for every minute of the quadrant, and their corresponding logarithms, it was attended with some degree of inconvenience, when used as a table of the logarithms of common numbers; because, when a number was proposed which was not exactly the same with some number denoting a natural sine, it was then necessary to find its logarithm by means of an arithmetical calculation, performed according to precepts which the author delivered in his work. This inconvenience, which was in part obviated by certain contrivances of Wright and Briggs, was not the only one; for there was another, which arose from the logarithms being sometimes +, or additive, and sometimes —, or negative; and which therefore required the knowledge of algebraic addition and subtraction. This last defect was occasioned partly by making the logarithm of radius 0, and those of the sines to increase; and partly by the compendious manner in which the author had formed the table; making the three columns of sines, cosines, and tangents, to serve also for the other three of cosecants, secants, and cotangents.

21. But this latter inconvenience was well remedied by John Speidell, in his *New Logarithms*, first published in 1617; which contained all the six columns, and these all of a positive form, by being taken the arithmetical complements of Napier's, that is, they were the remainders left by subtracting each of the latter from 10,000,000. And the former inconvenience was more completely removed by Speidell in a second table, given in the sixth impression of the former work, in the year 1624. This was a table of Napier's Logarithms for the integers 1, 2, 3, 4, 5, &c., to 1000, together with their differences and arithmetical complements; as also the halves of the said numbers, with their differences and arithmetical complements; which halves were consequently the logarithms of the square roots of the said numbers. Those logarithms are, however, a little varied in their form from Napier's, namely, so as to increase from 1, whose logarithm is 0, instead of decreasing to 1 or radius, whose logarithm Napier made 0 likewise; that is, Speidell's logarithm of any number n is equal to Napier's logarithm of its reciprocal $\frac{1}{n}$. So that, in this last table of Speidell's, the logarithm of 1 being 0, the logarithm of 10 is 2302584; the logarithm of 100 is twice as much, or 4605168; and that of 1000, thrice as much, or 6907753. The logarithms contained in this table are now commonly called hyperbolic logarithms; because they serve to express the areas contained between the curve of the hyperbola and its asymptote.

22. The celebrated inventor of the logarithms died in the year 1618; and in 1619 his son Robert Napier published a new edition of the *Logarithmorum Canonis Descriptio*, to which was now added the promised *Logarithmorum Canonis Constructio*, and other miscellaneous pieces written by his father and Mr. Briggs. This work was reprinted in France in 1620; also, nearly about this time, different mathematicians abroad published tables of logarithms of the same kind as those of Napier; as Benjamin Ursinus, mathematician to the elector of Brandenburg.

also the famous Kepler, who was the mathematician to the emperor Ferdinand II. and others.

23. Next to the discovery of logarithms, the most remarkable circumstance connected with their history is that improvement which they received in their form from Henry Briggs, who was, at the time of the publication of Napier's logarithms, professor of geometry in Gresham College, in London, and afterwards Savilian professor of geometry at Oxford, where he died in the year 1630.

24. On the first publication of Napier's logarithms, Briggs immediately applied himself to the study and improvement of them; and presently saw that it would be of advantage to change the scale; so that the logarithm of 1 being 0, as in Napier's form, the logarithm of 10 might be 1, that of 100 2, of 1000 3, and so on; whereas the logarithms of the same numbers, according to Napier's construction, were 2.302585, 4.605168, 6.907753, &c. This improvement Briggs communicated both to the public in his lectures, and to Napier himself, who afterwards said, that he had also thought of the same thing; as appears from the following extract, translated from the preface to Briggs's *Arithmetica Logarithmica*: 'Wonder not,' says he, 'that these logarithms are different from those which the excellent baron of Marchiston published in his *Admirable Canon*. For when I explained the doctrine of them to my auditors at Gresham College, in London, I remarked, that it would be much more convenient, the logarithm of the sine total being 0 (as in the *Canon Mirificus*), if the logarithm of the tenth part of the said radius, namely, of $5^{\circ} 44' 21''$, were 100000, &c., and concerning this, I presently wrote to the author; also, as soon as the season of the year, and my public teaching, would permit, I went to Edinburgh, where, being kindly received by him, I staid a whole month. But, when we began to converse about the alteration of them, he said, that he had formerly thought of it, and wished it; but that he chose to publish those that were already done, till such time as his leisure and health would permit him to make others more convenient. And, as to the nature of the change, he thought it more expedient, that 0 should be the logarithm of 1, and 100000, &c., the logarithm of radius, which I could not but acknowledge was much better; therefore, rejecting those I had before prepared, I proceeded, at his exhortation, to calculate these, and the next summer I went to Edinburgh, to show him the principal of them, and should have been glad to do the same the third summer, if it had pleased God to spare him so long.'

25. Thus it appears that Briggs was the inventor of the present scale of logarithms, in which 1 is the logarithm of 10, and 2 that of 100, &c., and that the share which Napier had in them was only advising Briggs to begin at the lowest number 1, and make the logarithms, or artificial numbers (as Napier had also called them), to increase with the natural numbers, instead of decreasing, which made no alteration in the figures that expressed Briggs's logarithms, but only in their affections or signs, changing them from negative to positive; for, according to Briggs's first intention, the logarithms of .001, .01, .1, 1, 10, 100, 1000,

&c., would have been +3, +2, +1, 0, -1, -2, -3, &c.; but, in conformity to the suggestion of Napier, they were made -3, -2, -1, 0, +1, +2, +3, &c., which is a change of no essential importance, as the scale of the system is the same in either case. And the reason why Briggs, after that interview, rejected what he had before done, and began anew, was probably because he had adapted his new logarithms to approximate sines of arcs, instead of the round or integer numbers, and not from their being logarithms of another system, as were those of Napier.

26. About the year 1618 Briggs published the first 1000 logarithms to eight places of figures, besides the index, under the title of *Logarithmorum Chilias Prima*: and in 1624 he produced his *Arithmetica Logarithmica*, a stupendous work for so short a time, containing the logarithms of 30,000 natural numbers, to fourteen places of figures besides the index; namely, from 1 to 20,000, and from 90,000 to 100,000, together with the differences of the logarithms; and in both these works the logarithms were calculated according to the system which had been agreed upon between him and the first inventor; that is, they were the same as the system which we commonly employ at the present time.

27. Soon after the publication of the *Arithmetica Logarithmica*, Adrian Vlacq, or Flack, completed the intermediate seventy chiliads, and republished it at Gouda, in Holland; thus making in the whole, the logarithms of all numbers from 1 to 100,000; but only to ten places of figures. He also added a table of artificial sines, tangents, and secants, to every minute of the quadrant.

28. Briggs himself also lived to complete a table of logarithmic sines and tangents for the 100th part of every degree of the quadrant, to fourteen places of figures, besides the index; together with a table of natural sines for the same parts, to fifteen places, and the tangents and secants of the same to ten places, with the construction of the whole. These tables were printed at Gouda, under the care of Adrian Vlacq, and nearly finished off before 1631. But the death of the author, which happened in 1630, prevented him from completing the application and uses of them. However, the performing of this office he recommended, when dying, to his friend Henry Gellibrand, then professor of astronomy in Gresham College; who added a preface, and the application of the logarithms to plane and spherical trigonometry, &c. The work was published in 1633, under the title of *Trigonometria Britannica*; and besides the arcs in degrees, and centesims of degrees, it has another column, containing the minutes and seconds, answering to the several centesims in the first column.

29. In the same year Vlacq printed at Gouda his *Trigonometria Artificialis*; sive *Magnus Canon Triangulorum Logarithmicus*, ad Decadas Secundorum Scrupulorum constructus. This work contains the logarithmic sines and tangents to ten places of figures, with their differences, for every ten seconds in the quadrant. To them is

also added Briggs's table of the first 20,000 logarithms; but carried only to ten places of figures, besides the index, with their differences. The whole is preceded by a description of the tables, and the application of them to plane and spherical trigonometry, chiefly extracted from Briggs's *Trigonometria Britannica*, mentioned above.

30. Gellibraud published also, in 1635, An *Institution Trigonometrical*, containing the logarithms of the first 10,000 numbers, with the natural sines, tangents, and secants, and the logarithmic sines and tangents for degrees and minutes, all to seven places of figures, besides the index; as also other tables proper for navigation, with the uses of the whole.

31. Having now given some account of such works on logarithms as seem most connected with their first discovery and subsequent improvement, we shall pass over many others, some of which, however, have been held in high repute, both for their accuracy, and the extent to which the tables have been carried. As, however, even the arrangement of the logarithms in the tables has received considerable improvements since the days of Napier, it may be proper to mention, that they were first reduced to the most convenient form by John Newton, in his *Trigonometria Britannica*, published at London in 1658.

32. Among the tables of logarithms which have been published of late years, in this country, there are two works most deservedly in repute, both for accuracy and convenience of arrangement: these are Dr. Hutton's *Mathematical Tables*, containing common, hyperbolic, and logistic logarithms, &c., and Taylor's *Tables of logarithms of all numbers, from 1 to 101,000*; and of the sines and tangents to every second of the quadrant. Several very accurate and well arranged collections of tables of logarithms have also been lately printed in France one which deserves to be particularly mentioned is Callet's stereotype edition of *Tables Portatives de Logarithmes*. These contain the logarithms of numbers from 1 to 108,000, and the logarithmic sines and tangents for every second, in the first five degrees, and for every ten seconds of the remaining degrees of the quadrant, and also for every 10,000th part of the arc, according to the new centesimal division of the quadrant. The logarithms are to seven decimal places.

33. But a more extensive collection of logarithmic tables than any we have yet mentioned, was begun in France in 1794, under the direction of C. Prony, who engaged not only to compose tables which should leave nothing farther to be desired with regard to accuracy, but to make them the most extended and most striking monument of calculation, which had ever been executed, or even imagined. In preparing this work, C. Prony availed himself of the advantage to be derived from the division of labor, by means of which, the greatest perfection of workmanship is obtained in the arts, with the least expense of money and time. By the united labors of C. Prony and his assistants, who were divided into three classes, two MS. copies of the tables were prepared; these composed seventeen volumes, large folio, and contained,

(1.) An introduction, consisting of an exposition of the analytical formulæ, the use of the trigonometrical table; and a number of auxiliary tables.

(2.) The natural sines for every 10,000th part of the quadrant, calculated to twenty-five places of decimals, with seven or eight columns of differences; to be published with twenty-two decimals, and five columns of differences.

(3.) The logarithms of these sines calculated to fourteen decimals, with five columns of differences.

(4.) The logarithms of the ratios of the sines to the arcs, for the first 5000 10,000th parts of the quadrant, calculated to fourteen decimals, with three columns of differences.

(5.) The logarithms of the tangents, corresponding with the logarithms of the sines.

(6.) The logarithms of the ratios of the tangents to the arcs, calculated like those in the fourth article.

(7.) Logarithms of numbers from 1 to 100,000, calculated to nineteen places of decimals.

(8.) The logarithms from 100,000 to 200,000, calculated to twenty-four decimals, in order to be published to twelve decimals, and three columns of differences.

The printing of this immense work was commenced under the auspices of the French government, but was suspended at the fall of the assignats, and has not since been resumed. After the overthrow of Buonaparte an offer was made by the British government (on the suggestion of Mr. Davies Gilbert, the present president of the Royal Society), to defray one-half of the expense attending the printing and publication of the work; but the offer was declined by the French government, but in a manner which showed that the feelings which dictated the offer were duly appreciated.

SECT. III.—THE CONSTRUCTION OF LOGARITHMS.

34. From the general explanation which has been given of the nature of logarithms, in § 1, it is not difficult to see how we may find the logarithms of as many numbers as we please. For the arithmetical series 0, 1, 2, 3, 4, &c., being assumed to denote the logarithms of the geometrical series

1, 10, 100, 1000, 10,000, &c.

if we find any number of arithmetical proportionals between every two terms of the former, and an equal number of geometrical proportionals between the corresponding terms of the latter; these arithmetical proportionals will be the logarithms of the corresponding geometrical proportionals.

35. The logarithms thus found will not indeed correspond exactly to any term in the series of whole numbers 2, 3, 4, 5, &c., but, proceeding upon the same principle, the logarithms of these may be also found, as in the following example, where it is proposed to determine the logarithm of the number 9: and, as the inserting of two or more geometrical proportionals between any two given numbers would require the extraction of the cube or some higher root, we shall carry on the operation by inserting only one mean,

which may be done by the extraction of the square root.

36. Because the logarithm of 1 is 0, and the logarithm of 10 is 1, we are to find an arithmetical mean between 0 and 1, and a geometrical mean between 1 and 10; the former will be $\frac{0+1}{2} = \frac{1}{2} = .5$, and the latter $\sqrt{1 \times 10} =$

$\sqrt{10} = 3.1622777$. Hence the logarithm of 3.1622777 is .5. Again, let an arithmetical mean be found between .5, the logarithm of 3.1622777, and 1, the logarithm of 10, and a geometrical mean between 3.1622777 and 10, the former will be $\frac{1+.5}{2} = \frac{1.5}{2} = .75$; and the

latter $\sqrt{10 \times 3.1622777} = 5.6234132$. Thus the logarithm of 5.6234132 is found to be .75. For a third operation, let an arithmetical mean be found between .75, the logarithm of 5.6234132, and 1, the logarithm of 10; also a geometrical mean between 5.6234132 and 10; the former will be $\frac{1+.75}{2} = .875$; and the latter

$\sqrt{10 \times 5.6234132} = 7.4989422$. Therefore the logarithm of 7.4989422 is .875.

Fourth operation. Let an arithmetical mean be found between .875, the logarithm of 7.4989422, and 1, the logarithm of 10; also a geometrical mean between 7.4989422 and 10; the former will be .9375, and the latter 8.6596431. Thus the logarithm of 8.6596431 is .9375.

Fifth operation. Let an arithmetical mean be found between .9375, the logarithm of 8.6596431, and 1 the logarithm of 10; also a geometrical mean between 8.6596431 and 10, the former will be .96875, and the latter 9.3057204. Thus the logarithm of 9.3057204 is .96875.

Sixth operation. As the geometrical mean last found exceeds 9, let there now be found an arithmetical mean between .9375, the logarithm of 8.6596431, and .96875 the logarithm of 9.3057204, the former will be .953125, and the latter 8.9768713. Thus the logarithm of 8.9768713 is .953125.

Proceeding in this manner, after twenty-five extractions of the square root, it will be found that the logarithm of 8.9999998 is .9542425, which may be taken also for the logarithm of 9, as it differs so little from it, that it is sufficiently exact for all practical purposes.

37. Having found the logarithm of 9, we may thence find the logarithms of all roots and powers of 9, as well as all multiples of those roots and powers, by 10, 100, 1000, &c. Thus

$$\begin{aligned}\log. 3 &= \log. \sqrt{9} = \frac{1}{2} \log. 9 = .4771213 \\ \log. 81 &= \log. 9^2 = 2 \times \log. 9 = 1.9084850 \\ \log. 30 &= \log. 3 + \log. 10 = 1.4771213.\end{aligned}$$

38. This method of computing the logarithms of numbers, by the finding of geometrical proportionals, is exceedingly tedious: it is, however, nearly the same as was employed by the first computers of logarithms; but the improvements which have been since made in the various branches of mathematics, and particularly in the doctrine of infinite series, have furnished much easier me-

thods of computing logarithms. These, as well as the nature and properties of logarithms, we now proceed to explain, by means of the principles of the common algebraic analysis, in the following manner.

39. Let r denote any positive number whatever, different from unity. Then, by assuming proper exponents, the powers of r may become equal to all positive numbers whatever, whether those numbers be whole or fractional. Thus if $r = 2$, we have $2^0 = 1$, $2^1 = 2$, $2^2 = 4$, $2^3 = 8$, $2^4 = 16$, &c. As to the intermediate numbers 3, 5, 6, 7, &c., they may be expressed, at least nearly, by fractional powers of 2. Thus, $2^{1.5850} = 3$, $2^{2.3219} = 5$, $2^{2.5850} = 6$, $2^{2.6073} = 7$, &c.

So also the powers of 10 may become, either exactly or nearly, equal to all positive numbers whatever. Thus,

$$\begin{array}{ll} 10^0 = 1 & 10^{-.7761} = 6 \\ 10^{-.3010} = 2 & 10^{-.8451} = 7 \\ 10^{-.4771} = 3 & 10^{-.9031} = 8 \\ 10^{-.6021} = 4 & 10^{-.9542} = 9 \\ & 10^1 = 10\end{array}$$

40. In general, if a denote any positive number, it is sufficiently evident, that it is possible to conceive a corresponding number A , such, that $r^A = a$; and A , that is the exponent of r , which gives a power equal to a , is called the logarithm of a .

41. From this manner of defining logarithms, we readily derive all their properties. For a and b denoting any two numbers; also A and B their logarithms; we have $r^A = a$, and $r^B = b$, therefore $r^A + r^B = ab$; but $r^A \times r^B = r^{A+B}$; therefore $A + B$ is the logarithm of ab ; that is, the sum of the logarithms of any two numbers is equal to the logarithm of the product. Again, $\frac{r^A}{r^B} = \frac{a}{b}$; but $\frac{r^A}{r^B} = r^{A-B}$; therefore, $A - B$

is the logarithm of $\frac{a}{b}$; that is, the difference of the logarithms of two numbers is equal to the logarithm of their quotient.

If we resume the equation $r^A = a$, we have $r^{nA} = a^n$, therefore nA is the logarithm of a^n ; and, since n may be either a whole number or a fraction, it follows, that the logarithm of any power of a number is equal to the logarithm of that number, multiplied by the exponent of the power; also, that the logarithm of any root of a number is equal to the logarithm of the number divided by the exponent of the root.

42. There may be various systems of logarithms, according to the different values which may be given to the number r , which is called the radical number of the system. In the common system of the logarithms, r is 10; but in the system of Napier it is 2.7182818. It is evident from the definition given in § 40, that the logarithm of the radical number in every system must be unity. In different systems, the logarithms of the same number are always to one another in a constant ratio. Suppose that A is the logarithm of the number a , the radical number of the system being r ; and A' the logarithm of the same number, according to another system,

the radical number of which is r' : Then $r^a = a$, and $r'^{A'} = a$; therefore $r^A = r'^{A'}$, and $r^{\frac{A}{A'}} = r'$. Thus it appears that the fraction $\frac{A}{A'}$ depends only on r , and r' ; and therefore must be the same whatever be the value of the number a .

43. Hence it follows, that if the logarithms of numbers, according to any one system, be given, the logarithms of the same numbers, according to any other proposed system, may be readily found. Thus, if the given system be the common logarithms, the radical number of which is 10, and it be required to find the logarithm of any number a , according to Napier's system, of which the radical number is 2.7182818; let A denote the logarithm of a , according to the former system; and x the logarithm of a , according to the latter. Then, by substituting 10 and 2.7182818, for r and r' ; also x for A , in the last equation of § 42, we have $10^{\frac{A}{x}} = 2.7182818$, and, from the nature of logarithms, $\frac{A}{x} \times \log. 10 = \log. 2.7182818$, § 41: Hence

$\frac{\log. 10}{\log. 2.7182818} \times A = .4342945 \times A$
 $= 2.3025851 \times A$. Thus it appears, that Napier's logarithm of any number is equal to the common logarithm of the same number, multiplied by 2.3025851; or divided by .4342945.

44. Let us now denote any number whatever by y , and its logarithm by x ; then, r representing as before the radical number of the system, the relation between a number and its logarithm is represented by the algebraic equation $r^x = y$. This equation suggests two subjects of enquiry, both capable of being resolved by means of the algebraic method of analysis. These are: first, To determine y when x is given; or to determine the number which corresponds to a given logarithm. Secondly, To determine x when y is given; that is, to determine the logarithm corresponding to a given number.

45. We proceed to the first subject of enquiry, namely, to find an algebraic expression for y , in terms of x and r ; or to express, generally, any number by means of its logarithm, and the base or radical numbers of the system: for this purpose, let us assume

$r^x = A + Bx + Cx^2 + Dx^3 + Ex^4 + \&c.$
 Here $A, B, C, D, \&c.$, are supposed to be co-efficients independent of x . Let x denote any other quantity; then, in like manner, we have

$r^x = A + Bx + Cx^2 + Dx^3 + Ex^4 + \&c.$
 Taking now the difference between the assumed equations, and dividing both sides of the result by $x - z$, we have

$$\frac{r^x - r^z}{x - z} = \frac{B(x - z) + C(x^2 - z^2) + D(x^3 - z^3) + \&c.}{x - z}$$

Now it is well known, that each of the quantities $x - z, x^2 - z^2, x^3 - z^3, x^4 - z^4, \&c.$, which compose the latter part of this equation, is divisible by $x - z$; therefore, these several divisions being actually effected, the last equation may otherwise be expressed thus

$$\frac{r^x - r^z}{x - z} = B + C(x + z) + D(x^2 + xz + z^2) + E(x^3 + x^2z + xz^2 + z^3) + \&c.$$

46. That we may expand the first part of this equation into the form of a series, let us express the numerator $r^x - r^z$ thus, $r^z(r^x - r^z - 1)$; then, putting $1 + a$ for r , we have

$$\frac{r^x - r^z}{x - z} = \frac{r^z}{x - z} \left\{ (1 + a)^{x - z} - 1 \right\}.$$

Now, by the binomial theorem, the quantity $(1 + a)^{x - z}$, when expanded into a series, is $1 + \frac{(x - z)}{1} a + \frac{(x - z)(x - z - 1)}{1 \cdot 2} a^2 + \frac{(x - z)(x - z - 1)(x - z - 2)}{1 \cdot 2 \cdot 3} a^3 + \&c.$

Therefore, subtracting unity from this series, and dividing each of the remaining terms by $x - z$, as indicated by the latter part of the last equation, we have $\frac{r^x - r^z}{x - z} = r^z \left(a + \frac{x - z - 1}{2} a^2 + \frac{(x - z - 1)(x - z - 2)}{2 \cdot 3} a^3 + \&c. \right)$

Hence it appears that

$$r^x \left(a + \frac{x - z - 1}{2} a^2 + \frac{(x - z - 1)(x - z - 2)}{2 \cdot 3} a^3 + \frac{(x - z - 1)(x - z - 2)(x - z - 3)}{2 \cdot 3 \cdot 4} a^4 + \&c. \right) = B + C(x + z) + D(x^2 + xz + z^2) + E(x^3 + x^2z + xz^2 + z^3) + \&c.$$

This last equation, by supposing $z = x$, becomes

$$r^x \left(a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \frac{a^5}{5} \&c. \right) = B + 2Cx + 3Dx^2 + 4Ex^3 + 5Fx^4 + \&c.$$

and substituting for r^x the series

$$A + Bx + Cx^2 + Dx^3 + Ex^4 + \&c.$$

also, putting, for the sake of brevity,

$$a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \frac{a^5}{5} - \&c. = m$$

we find

$$Am + Bmx + Cmx^2 + Dmx^3 + Emx^4 + \&c. = B + 2Cx + 3Dx^2 + 4Ex^3 + 5Fx^4 + \&c.$$

Hence, by putting the co-efficients of the like powers of x in each series equal to one another, we find

$$B = \frac{Am}{2}, C = \frac{Bm}{2}, D = \frac{Cm}{3}, E = \frac{Dm}{4},$$

$$F = \frac{Em}{5}, \&c.$$

Thus we have obtained a series of equations, by which all the co-efficients, except A , the first, are determined. It is however readily obtained from the assumed equation $r^x = A + Bx + Cx^2 + \&c.$, by taking $x = 0$; for then the first part of the equation of r^x becomes unity, and all the terms of the second part vanish, except A ; thus $A = 1$,

$$B = \frac{m}{1} C = \frac{m^2}{1 \cdot 2}, D = \frac{m^3}{1 \cdot 2 \cdot 3}, E = \frac{m^4}{1 \cdot 2 \cdot 3 \cdot 4},$$

$$F = \frac{m^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}, \&c.; \text{ and, by substituting these}$$

values in the assumed series, we find $y = r^x = 1$

$$+ \frac{mx}{1} + \frac{m^2 x^2}{1 \cdot 2} + \frac{m^3 x^3}{1 \cdot 2 \cdot 3} + \frac{m^4 x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

47. Thus we have obtained a series for y , which will always converge, whatever be the values of the quantities m and x . Before, however, the series can be applied to practice, it will be necessary to compute the value of m , which, by putting $r = 1$ for its value a , is equal to this other series

$$\frac{r-1}{1} - \frac{(r-1)^2}{2} + \frac{(r-1)^3}{3} - \frac{(r-1)^4}{4} + \frac{(r-1)^5}{5} -$$

&c. But as this last series will not converge, unless $r-1$ be less than unity, it will be necessary to have recourse to another method of obtaining its sum than by the mere addition of its terms.

48. Resuming, therefore, the equation

$$r = 1 + \frac{mx}{1} + \frac{m^2 x^2}{1 \cdot 2} + \frac{m^3 x^3}{1 \cdot 2 \cdot 3} + \frac{m^4 x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

let us suppose $x = 1$; and we have

$$r = 1 + \frac{m}{1} + \frac{m^2}{1 \cdot 2} + \frac{m^3}{1 \cdot 2 \cdot 3} + \frac{m^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

This series gives the value of r , when m is known. Therefore, if we suppose a system of logarithms to be such, that $m = 1$, and put e for the radical number of that system, we have

$$e = 1 + \frac{1}{1} + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

and by reducing a sufficient number of the terms of this series to decimal fractions, and taking their sum, we readily find $e = 2.7182818$, nearly. Now, as e is the radical number of a system, in which $m = 1$, for the same reason that

$$r = 1 + \frac{mx}{1} + \frac{m^2 x^2}{1 \cdot 2} + \frac{m^3 x^3}{1 \cdot 2 \cdot 3} + \&c.$$

we have

$$e^r = 1 + \frac{x}{1} + \frac{x^2}{1 \cdot 2} + \frac{x^3}{1 \cdot 2 \cdot 3} + \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

and as this must be true, whatever be the value of x , we may suppose $x = m$; hence we have

which last series we have already found to be $= r$, therefore $e^m = r$; and taking the logarithms of both sides of the equation, $m \times \log. e = \log. r$, hence at last we find $m = \frac{\log. r}{\log. e}$;

since the logarithm of the radical number of any system is unity, $m = \frac{1}{\log. e}$. Let this value of

m be substituted in the series of § 46, and we have $y = r^x = 1 + \frac{x}{1 \cdot \log. e} + \frac{x^2}{1 \cdot 2 \cdot (\log. e)^2}$

+ $\frac{x^3}{1 \cdot 2 \cdot 3 \cdot (\log. e)^3} + \&c.$, where it is to be observed that x and $\log. e$ are logarithms belonging to the same system; and by this series a number may be found corresponding to any given logarithm whatever.

49. We are next to investigate a series which shall express the logarithm by means of the number. This may be readily obtained, if we recollect that in § 47 we found

$$m = \frac{r-1}{1} - \frac{(r-1)^2}{2} + \frac{(r-1)^3}{3} - \frac{(r-1)^4}{4} + \&c.$$

and that in § 48 we also found $\log. r = m \times \log. e$, hence we have

$$\log. r = \log. e \left\{ \frac{r-1}{1} - \frac{(r-1)^2}{2} + \frac{(r-1)^3}{3} \right.$$

+ $\&c.$ } Now, this equation must

hold true, whatever be the value of r ; we may therefore substitute 1 for r , and conse-

quently y for $r-1$; where y denotes any number whatever; hence we find

$$\log. (1+y) = \log. e \left(y - \frac{y^2}{2} + \frac{y^3}{3} - \frac{y^4}{4} + \right.$$

&c.) Thus we have found a series which expresses the logarithm of any number whatever, by means of the number itself, and the logarithm of another given number, e .

50. The series which we have just now found will be of little or no use in the actual construction of logarithms, unless y be a small fraction; we may however derive from it another series, much better adapted to that purpose, in the following manner:—

Let us put M for $\log. e = \frac{1}{m}$. Then, because

$$\log. (1+y) = M \left(y - \frac{y^2}{2} + \frac{y^3}{3} - \frac{y^4}{4} + \&c. \right)$$

if we substitute $-y$ for $+y$ we shall have

$$\log. (1-y) = M \left(-y - \frac{y^2}{2} - \frac{y^3}{3} - \frac{y^4}{4} - \&c. \right)$$

and subtracting this last equation from the former,

$$\log. (1+y) - \log. (1-y) = 2M \left(y + \frac{y^3}{3} + \frac{y^5}{5} \right.$$

+ $\&c.$) But, from the nature of logarithms,

$$\log. (1+y) - \log. (1-y) = \log. \frac{1+y}{1-y}.$$

Therefore

$$\log. \frac{1+y}{1-y} = 2M \left(y + \frac{y^3}{3} + \frac{y^5}{5} + \frac{y^7}{7} + \&c. \right)$$

Or, putting z for $\frac{1+y}{1-y}$ and therefore $\frac{z-1}{z+1}$ for

$$y, \log. z = 2M \left\{ \frac{z-1}{z+1} + \frac{1}{3} \left(\frac{z-1}{z+1} \right)^3 + \frac{1}{5} \left(\frac{z-1}{z+1} \right)^5 + \&c. \right\}$$

and, by a proper application of this series, which always converges, the logarithms of numbers may be found with great facility.

51. For example, let us suppose that it is required to compute the logarithm of 2; then, because $z = 2$, we have $\frac{z-1}{z+1} = \frac{1}{3}$, therefore

$$\log. 2 = 2M \left(\frac{1}{3} + \frac{1}{3 \cdot 3^3} + \frac{1}{5 \cdot 3^5} + \frac{1}{7 \cdot 3^7} + \&c. \right)$$

This series converges very fast, for the eighth term does not exceed $\frac{1}{100000000}$; by re-

ducing, therefore, the first seven terms to decim-

als, and taking their sum, find

$$\log. 2 = .3465736 \times 2M = .6931472 \times \log. e;$$

but we cannot find the absolute value of the

logarithm of 2, without previously assigning the

particular system to which the logarithm re-

quired is to belong. The most simple hypothe-

sis we can assume is, that $\log. e = 1$; hence we

have $\log. 2 = .6931472$. This system, which

corresponds to the equation $y = e^x$ (where y de-

notes a number, x its logarithm, and e the base

of the system, $= 2.7182818$), is the same as that

first adopted by Napier; the logarithms of which

are also called hyperbolic, for the reason already

assigned in § 21.

52. It appears therefore, from §§ 49 and 50, that Napier's, or the hyperbolic logarithm of any numbers x , is equal to either of these two series

$$\frac{x-1}{1} - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + \&c.$$

$2 \left\{ \frac{x-1}{x+1} + \frac{1}{3} \left(\frac{x-1}{x+1} \right)^3 + \frac{1}{5} \left(\frac{x-1}{x+1} \right)^5 + \&c. \right\}$ and that the logarithm of x , according

to any other system, is equal to the hyperbolic logarithm of the same number, multiplied by a certain constant quantity $M = \log. e$; which, being peculiar to that system, has been called by writers on logarithms the modulus of the system.

*Now it appears, by recurring to § 47, that

$\frac{1}{\log. e}$, or m , is equal to this series

$$r-1 - \frac{(r-1)^2}{2} + \frac{(r-1)^3}{3} - \&c.$$

which is evidently the hyperbolic logarithm of r , the radical number of the system: hence it follows, that the modulus of any system of logarithms is the reciprocal of the hyperbolic logarithm of the radical number of that system.

53. In the common system of logarithms, the radical number being 10, the modulus of the system may be found by computing the hyperbolic logarithm of 10. Now, by the latter series of § 52, we have

$$\text{hyp. log. } 10 = 2 \left\{ \frac{9}{11} + \frac{1}{3} \left(\frac{9}{11} \right)^3 + \frac{1}{5} \left(\frac{9}{11} \right)^5 + \&c. \right\}$$

But, as this series converges too slowly to be of any use, we may find another that converges faster, by considering, that since $10 = 2 \times 5$, therefore, $\log. 10 = \log. 2 + \log. 5$: Now we have already found hyperbolic logarithm 2; it is only necessary, therefore, to compute hyperbolic logarithm 5.

54. But, in seeking hyperbolic logarithm 10, it will be convenient to begin with even a less number than 5; and, for this purpose, we shall investigate a rule, by which, the logarithm of any number being supposed given, the logarithm of another number, a little greater than the given one, may be found with great facility

Let n be a number, whose logarithm is given, and $n+v$ another number, whose logarithm is required; then, since $n+v = n \left(1 + \frac{v}{n} \right)$, it follows, that $\log. (n+v) = \log. n + \log. \left(1 + \frac{v}{n} \right)$. If we now put $z = 1 + \frac{v}{n}$, we

have $z-1 = \frac{v}{n}$, and $z+1 = 2 + \frac{v}{n}$, and

therefore, $\frac{z-1}{z+1} = \frac{v}{2n+v}$. Hence, by substituting $1 + \frac{v}{n}$ for z , and $\frac{v}{2n+v}$ for $\frac{z-1}{z+1}$

in the series for the logarithm of z , found in § 50, we have

$$\log. (n+v) = \log. n + 2M \left\{ \frac{v}{2n+v} + \frac{1}{3} \frac{v^3}{(2n+v)^3} + \frac{1}{5} \frac{v^5}{(2n+v)^5} + \&c. \right\}$$

which is the series we proposed to investigate.

55. To calculate the hyperbolic logarithm of 10 by this series, we may take $n=8$ and $v=2$,

then $\frac{v}{2n+v} = \frac{2}{18} = \frac{1}{9}$, and, remarking that

$\log. 8 = 3 \times \log. 2$, we have

$$\text{hyp. log. } 10 = 3 \times \text{hyp. log. } 2 + 2 \left(\frac{1}{9} + \frac{1}{3} \right)$$

$$\left(\frac{1}{9^3} + \frac{1}{5 \cdot 9^5} + \&c. \right)$$

This series converges very fast, so that the three first terms are sufficient to give a result true to the seventh decimal; and accordingly their sum, when multiplied by the co-efficient 2, will be found $= .2231435$. Now we formerly found hyperbolic logarithm $2 = .6931472$, § 51, therefore, to the number just now found, let hyperbolic logarithm $8 = 3$ hyperbolic logarithm $2 = 2.0794416$ be added, and the result, 2.3025851 , will be the hyperbolic logarithm of 10; the reciprocal of which, or $\frac{1}{2.3025851} =$

$.4342945$ is the modulus of the common system of logarithms.

56. We may now find the common logarithm of 2; for nothing more is necessary than to multiply its hyperbolic logarithm already found, § 51, by the modulus, $.4342945$; or divide it by 2.3025851 , the reciprocal of the modulus, and, in either way, we find the common logarithm of 2 to be $.3010300$. The common logarithm of

5 may now also be found; for, since $5 = \frac{10}{2}$,

we have $\log. 5 = \log. 10 - \log. 2 = 1 - .3010300 = .6989700$.

57. We have investigated a series, by which the logarithm of $n+v$ may be found from that of n ; or the logarithm of n from that of $n+v$. We shall now investigate another series, by means of which, and the logarithms of any two of these three quantities, $n-v$, n , $n+v$, the logarithm of the remaining quantity may be found.

Because $\frac{n^2}{(n-v)(n+v)} = \frac{n^2}{n^2-v^2}$, therefore

$$2 \log. n - \log. (n-v) - \log. (n+v) = \log. \frac{n^2}{n^2-v^2}. \text{ Let us suppose } \frac{n^2}{n^2-v^2} = z, \text{ then } z -$$

$$1 = \frac{v^2}{n^2-v^2}, \quad z+1 = \frac{2n^2-v^2}{n^2-v^2} \text{ and } \frac{z-1}{z+1}$$

$= \frac{2v^2}{2n^2-v^2}$. Let these values of z and $\frac{z-1}{z+1}$ be

inserted in the series of § 50, and we presently have $2 \log. n = \log. (n-v) + \log. (n+v) + 2M \times \left\{ \frac{v^2}{2n^2-v^2} + \frac{1}{3} \left(\frac{v^2}{2n^2-v^2} \right)^3 + \&c. \right\}$

58. We shall conclude this section by showing the application of the three series which have been investigated in §§ 51, 54, and 57, to the calculation of the common logarithms of

the numbers between 1 and 10; and, as it will be most convenient in practice to compute the common logarithm directly, instead of first finding the hyperbolic logarithm, and afterwards multiply by the modulus of the common system, we shall put down each series in a form suited to that purpose. The value of v in the two series last found will generally be unity, we shall therefore put them down under that form.

Let $N = 2$ $M = .8685889638 + \&c.$

Let $n - 1, n, n + 1$ denote three numbers.

Put $\frac{n-1}{n+1} = A; \frac{1}{2n+1} = B; \text{ and}$

$$\frac{1}{2n^2-1} = C.$$

$$\text{I. Log. } n = NA + \frac{NA^3}{3} + \frac{NA^5}{5} + \frac{NA^7}{7}$$

+ &c.

$$\text{II. Log. } (n+1) = \log. n. + NB + \frac{NB^3}{3} + \frac{NB^5}{5} + \&c.$$

$$\text{III. } 2 \text{ Log. } n = \log. (n-1) + \log. (n+1)$$

$$NC + \frac{NC^3}{3} + \frac{NC^5}{5} + \&c.$$

59. *Example 1.* It is required to find the common logarithm of 2, to six places of figures, by the first series.

Here $n = 2, A = \frac{n-1}{n+1} = \frac{1}{3}$, and the calculation will stand as below.

$$N = .8685890 \quad NA = .2895297$$

$$NA^3 = .0321700 \quad \frac{NA^3}{3} = .0107233$$

$$NA^5 = .0035944 \quad \frac{NA^5}{5} = .0007149$$

$$NA^7 = .0003972 \quad \frac{NA^7}{7} = .0000567$$

$$NA^9 = .0000441 \quad \frac{NA^9}{9} = .0000049$$

$$NA^{11} = .0000049 \quad \frac{NA^{11}}{11} = .0000004$$

$$.3010299$$

The log. of 2 to six decimals is .301030.

Example 2. Required the common logarithm of 3 to six places of figures, having given the logarithm of 2, by the second series.

$$\text{Here } n+1 = 3, n = 2, B = \frac{1}{2n+1} = \frac{1}{5}.$$

$$N = .8685890 \quad NB = .1737178$$

$$NB^3 = .0069487 \quad \frac{NB^3}{3} = .0023162$$

$$NB^5 = .0002779 \quad \frac{NB^5}{5} = .0000556$$

$$NB^7 = .0000111 \quad \frac{NB^7}{7} = .0000016$$

$$.1760912$$

$$\text{Add log. 2} = .3010299$$

$$.4771211$$

$$\text{log. of 3 to six places is } .477121$$

The logarithms of 2 and 3 being found, we hence find $\log. 4 = 2 \log. 2 = .6020600$

$$\log. 5 = \log. 10 - \log. 2 = .6989700$$

$$\log. 6 = \log. 2 + \log. 3 = .778151$$

$$\log. 8 = 3 \log. 2 = .903090$$

$$\log. 9 = 3 \log. 3 = .954242$$

Example 3. Having given the logarithms of 6 and 8, it is required from these to determine the logarithms of 7 to six places of figures, by the third series.

$$\text{Here } n = 7, C = \frac{1}{2n^2-1} = \frac{1}{97}$$

$$N = .8685890, NC = .0089545$$

$$NC^3 = .0000010 \quad \frac{NC^3}{3} = .0000003$$

$$.0089548$$

$$\log. 6 = .7781513$$

$$\log. 8 = .9030900$$

$$2)1.6901961$$

$$.8450980$$

$$\log. \text{ of } 7 = .845098$$

Instead of finding the logarithm of 7 from the logarithms of 6 and 8, we might have otherwise found it from those of 5 and 6, or those of 8 and 9; in the former case we should have had $n-1 = 5,$

$$n = 6, n+1 = 7, \text{ and } C = \frac{1}{71}; \text{ and therefore}$$

$$\log. 7 = 2 \log. 6 - \log. 5 - \left\{ \frac{N}{71} + \frac{N}{3 \cdot 71^3} + \frac{N}{5 \cdot 71^5} + \&c. \right\} \text{ and in the latter case } n = 1 - 7,$$

$$n = 8, n+1 = 9, C = \frac{1}{127}; \text{ and hence}$$

$$\log. 7 = 2 \log. 8 - \log. 9 - \left\{ \frac{N}{127} + \frac{N}{3 \cdot 127^3} + \&c. \right\}$$

60 & 61. Proceeding in this manner, we may find the logarithms of as many numbers as we please, by deriving them one from another. Thus we have

$$\log. 12 = \log. 2 + \log. 6.$$

$$2 \log. 11 = \log. 10 + \log. 12 + N \left\{ \frac{1}{241} + \frac{1}{3 \cdot 241^3} + \&c. \right\}$$

$$\log. 14 = \log. 2 + \log. 7.$$

$$2 \log. 13 = \log. 12 + \log. 14 + N \left\{ \frac{1}{137} + \frac{1}{3 \cdot 137^3} + \&c. \right\}$$

and in this way might a table of logarithms be calculated; it would however be necessary to compute the logarithms of the numbers at the beginning of the table, to many more figures than were intended to be retained; because, that at each operation, the last figure of the logarithm is set down only to the nearest figure. But, in constructing a table, there are many expedients by which the calculations may be abridged; and these we cannot here find room to explain; and must therefore refer the curious reader to Dr. Hutton's Mathematical Tables, where he will meet with ample information on the subject.

62. *On the method of computing logarithmic sines, cosines, &c.*—A table of the logarithms of numbers being computed, by the methods explained above, one of logarithmic sines, &c., may easily be formed from it, by taking the logarithms of the numbers which represent the natural sines, &c.; and this, the most ready and convenient method, is that which has generally been used. But the logarithmic sines, &c., may be computed independently of a knowledge of the logarithms of natural numbers; or, with the aid of a table of logarithms, they may be obtained without reference to natural sines; and even without the aid of either the one or the other, as we shall shortly explain.

Tables of logarithmic sines, &c., are generally adapted to a radius whose logarithm is 10, but they can be more conveniently computed by assuming the radius unity; and 10 being added to the logarithms computed on that supposition, we have the logarithmic sines, &c., to the common tabular radius.

The length of an arc of 1° , to radius unity is $\cdot 01745329252$, &c.; and this, multiplied by the degrees contained in any given arc, thus the length of that arc, to radius 1, and it is this length which is to be understood in what follows, when the length of an arc is said to be given.

63. It has been shown in the article *FLUXIONS*, in this work, that if M be $\cdot 43429$, &c., the modulus of the common system of logarithms, then the logarithm of x is the fluent of $M \frac{\dot{x}}{x}$.

And if x be any arc whose sine is y , then $y = \frac{x^3}{2 \cdot 3} + \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{x^7}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}$; &c.;

whence $\dot{y} = \dot{x} - \frac{x^2 \dot{x}}{2} + \frac{x^4 \dot{x}}{2 \cdot 3 \cdot 4} - \frac{x^6 \dot{x}}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}$,

&c.; and consequently by division $\frac{\dot{y}}{y} = \frac{\dot{x}}{x} - \frac{x \dot{x}}{3} + \frac{x^3 \dot{x}}{45} - \frac{2x^5 \dot{x}}{945} + \frac{x^7 \dot{x}}{4725}$, &c.; and the fluent of $M \frac{\dot{y}}{y}$, or $\log. y = \log. x - M \cdot \left\{ \frac{x^2}{6} + \frac{x^4}{180} + \frac{x^6}{2835} + \frac{x^8}{3780} \right\}$, &c., or the tabular logarithm of $y = 10 + \log. x - M \cdot \left\{ \frac{x^2}{6} + \frac{x^4}{180} + \frac{x^6}{2835} + \frac{x^8}{3780} \right\}$, &c.

64. Otherwise; let $x = \frac{1-y}{1+y}$, y being the natural sine; then $y = \frac{1-x}{1+x}$, and $\frac{\dot{y}}{y} = \frac{-2\dot{x}}{1-x^2} = -2 \cdot \left\{ \dot{x} + x^3 \dot{x} + x^5 \dot{x} + x^7 \dot{x}, \&c. \right\}$; hence the fluent of $M \frac{\dot{y}}{y}$, or $\log. y = -2M \cdot \left\{ x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7}, \&c. \right\}$; or the tabular log. of $y = 10 - 2M \cdot \left\{ x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7}, \&c. \right\}$.

By the former of these series a table of logarithmic sines may be computed without a knowledge of the corresponding natural sines,

and by the latter without the aid of a table of logarithms, the natural sines being given.

65. We shall now show how such a table may be computed without a knowledge of either logarithms or natural sines.—Let x be any given arc, of which it is required to find the logarithmic cosine y . We have $y = 1 - \frac{x^2}{2} +$

$\frac{x^4}{2 \cdot 3 \cdot 4} - \frac{x^6}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}$; whence $\frac{\dot{y}}{y} = -x\dot{x} - \frac{x^3 \dot{x}}{3} - \frac{2x^5 \dot{x}}{15} + \frac{17x^7 \dot{x}}{315}$, &c.; and the fluent of $M \frac{\dot{y}}{y}$,

the log. cosine of $x = -M \left\{ \frac{x^2}{2} + \frac{x^4}{12} + \frac{x^6}{45} + \frac{17x^8}{2520} \right\}$, &c.; and the tabular log. cos. $x = 10$

$- M \cdot \left\{ \frac{x^2}{2} + \frac{x^4}{12} + \frac{x^6}{45} + \frac{17x^8}{2520} \right\}$, &c.; whence

the cosine is obtained without the aid of either logarithms or natural numbers.

As the cosine of an arc is the sine of its complement, this last series will give the sines as well as the cosines of all arcs. Like expressions might easily be deduced for the secants and tangents of arcs; but, our object being simply to show the manner in which such expressions may be obtained, we leave it to the student to apply what we have here given to any other purpose that he may think proper.

Of proportional or logarithmic logarithms.—These logarithms are adapted to making proportions among sexagesimals, and were particularly intended by Dr. Maskelyne, who first formed them, to facilitate the finding of the Greenwich time, corresponding to the distance of the moon from the sun or a star. If the change in the lunar distance in three hours, as given in the Nautical Almanac, be called m , and it be required to find the time x , corresponding to any other less, but given change n , in the distance, the proportion is $m : n :: 3^h : x = \frac{3^h n}{m}$; whence

$\log. m - \log. n = 3^h - \log. x$. Now 3^h and x being expressed in seconds of time, $\log. 3^h - \log. x$ is the proportional logarithm of x ; and similarly, $\log. 3^h - \log. m$ is the proportional logarithm of m , and $\log. 3^h - \log. n$ is the proportional logarithm of n . Hence $\log. m - \log. n = \text{prop. log. } x \text{ becomes } (\log. 3^h - \text{prop. log. } m) - (\log. 3^h - \text{prop. log. } n) = \text{prop. log. } x$; or $\text{prop. log. } n - \text{prop. log. } m = \text{prop. log. } x$.

Again, if $m : n :: o : p$; m, n, o , and p being any sexagesimal quantities; we should have by reducing them all to the same denomination $p = \frac{o n}{m}$; or $\log. p = \log. o + \log. n - \log. m$; or, changing them for proportional logarithms, $\log. 3^h - \text{prop. log. } p = \log. 3^h - \text{prop. log. } o + \log. 3^h - \text{prop. log. } n - \log. 3^h + \text{prop. log. } m$; or $\text{prop. log. } p = \text{prop. log. } o + \text{prop. log. } n - \text{prop. log. } m$; so that proportions are made with these logarithms precisely as they are with common logarithms.

It follows, from the construction of proportional logarithms, that the logarithm of the largest interval which they are made to comprehend is always nothing; as in those adapted to

three hours, the logarithm of three hours is nothing.

66. Proportional logarithms greatly facilitate the taking of proportional points among sexagesimal quantities, whether in time or in arc; for the hours, minutes, and seconds of time may be considered as degrees, minutes, and seconds of arc.

Example 1.—If the altitude of the sun increase $38^{\circ} 15'$ in $4^{\text{h}} 20'$; what will it increase in $1^{\text{h}} 32'$?

Here the proportion is $4^{\text{h}} 20' \cdot 1^{\text{h}} 32' :: 38^{\circ} 15' : 14^{\circ} 34'$, the answer; or, by proportional logarithms.

$4^{\text{h}} 20'$	prop. log.	1.6185
$1^{\text{h}} 32'$	ditto	2.0378
$38^{\circ} 15'$	ditto	6726
		2.7104
$14^{\circ} 34'$	ditto	2.0919

Example 2.—If the change in the lunar distance in 3^{h} be $1^{\circ} 42' 14''$, what interval of time will correspond to a change of $37' 5''$ in the distance?

$37' 5''$	prop. log.	6861
$1^{\circ} 42' 14''$	ditto	2457

Ans. $1^{\text{h}} 5^{\text{m}} 18^{\text{s}}$ ditto 4404 diff.

SECT. IV.—OF CERTAIN CURVES RELATED TO LOGARITHMS.

68. The discovery of logarithms suggested to mathematicians the idea of curve lines, which might have similar properties to those numbers: hence the origin of the logarithmic, or, as it has been also called, the logistic curve, the nature and properties of which we now proceed to explain.

69. Plate LOGARITHMS, fig. 11. Let CD be the logarithmic curve, and AB its base or abscissa, in which let there be taken any number of points, $P, P', P'', \&c.$, so that the lines $AP, AP', AP'', \&c.$ may constitute an arithmetical progression; then, if perpendiculars or ordinates, $PM, P'M', P''M'', \&c.$, be drawn, meeting the curve in the points $M, M', M'', \&c.$, its nature is such, that the ordinates $PM, P'M', P''M'', \&c.$ constitute a geometrical progression. Hence, and from the properties of logarithms, it appears, that the abscissas $AP, AP', AP'', \&c.$, may be considered as the logarithms of their corresponding ordinates $PM, P'M', P''M'', \&c.$, respectively.

70. That we may express the relation between any abscissa and its corresponding ordinate, by means of an equation, let us put the ordinate at the point A , or $AC, = 1$; take Ap , a given portion of the abscissa, and put pm , the corresponding ordinate, $= a$; take $pp', pp'', \&c.$, in the abscissa, equal to one another, and to Ap ; and let $AP = x \times Ap$; draw the ordinates $p m', p'' m'',$

$\&c.$, also PM . Then, from the nature of continued proportionals, $p' m' = a^2, p'' m'' = a^3, \&c.$, to PM , which will be expressed by a^x ; hence, if we put $PM = y$, we have $a^x = y$ for the equation of the curve.

71. From this equation, as well as by other methods all the properties of the logarithmic curve may be derived. We shall briefly mention some of the most remarkable.

I. The base AB is an asymptote to the curve.

II. If PM be an ordinate to the curve at M , and MQ a tangent at the same point, the subtangent PQ is a constant quantity, and equal to the modulus of the particular logarithmic system, to which the curve belongs.

III. The curvilinear space, comprehended between any two ordinates, AC, PM , is equal to the rectangle contained by PQ the subtangent and $PM - AC$ the difference of the ordinates.

72. There is yet another curve, the properties of which are analogous to those of logarithms; namely, the common hyperbola. Fig. 12. Let C be its centre, and CD, CE , its asymptotes, in either of which, let the points $A, A', A'', A''', \&c.$, be taken, so that $CA, CA', CA'', CA''', \&c.$, may be continued geometrical proportionals; draw $AB, A'B', A''B'', A'''B''', \&c.$, parallel to the other asymptote, meeting the curve in $B, B', B'', B''', \&c.$, and join $CB, CB', CB'', CB''', \&c.$ Then it is demonstrated, by writers on conics, that the hyperbolic sectors $CB B', CB' B'', CB'' B''', \&c.$, are equal to each other; and that the quadrilateral spaces $ABB'A', A'B'B''A'', A''B''B'''A''', \&c.$, are also equal to one another, and to each of the sectors. Hence the sectors, $CB B', CB' B'', CB'' B''', \&c.$, or the quadrilateral figures $ABB'A', A'B'B''A'', A''B''B'''A''', \&c.$, have equal differences, while their corresponding abscissas $CA, CA', CA'', \&c.$, have equal ratios to one another, viz. the ratio of CA to CA' : thus the former are analogous to the logarithms of the latter.

73. Let II be the vertex of the hyperbola, draw HG and IK parallel to the asymptotes, so as to form the rhombus $HGCK$; then, putting $CK = 1$, if CP denote any number whatever, and PQ be drawn parallel to the other asymptote, the hyperbolic area $KIIQP$ will serve to express the logarithm of CP , according to a system, the modulus of which is denoted by the area of the rhombus $CKHG$. If the asymptotes contain a right angle, the area of the rhombus will be $= 1$, and thus the hyperbolic areas will express Napier's or the hyperbolic logarithms. But any system of logarithms whatever may be represented by hyperbolic areas; thus, if the asymptotes contain an angle of $25^{\circ} 44' 25'' .5$, the area of the rhombus will be $.43429448, \&c.$, viz. equal to the modulus of the common system of logarithms, and therefore the hyperbolic areas equal to the common logarithms.

LOG-BOARD, a sort of table, divided into several columns, containing the hours of the day and night, the direction of the winds, the course of the ship, and all the material occurrences that

happen during the twenty-four hours, or from noon to noon; together with the latitude by observation. From this table the different officers of the ship are furnished with materials to com-

pile their journals, wherein they likewise insert whatever may have been omitted, or reject what may appear superfluous in the log-board.

LOG-BOOK, a book into which the contents of the log-board are daily copied at noon, together with every circumstance deserving notice that may happen to the ship, or within her cognisance, either at sea or in a harbour, &c. The intermediate divisions or watches of the log-book, containing four hours each, are usually signed by the commanding officers in ships of war or East Indiamen. See **NAVIGATION**.

LOG-GATS, *n. s.* Probably from log, a game. See the extract from Hamner.

Loggats is the ancient name of a play or game, which is one of the unlawful games enumerated in the thirty-third statute of Henry VIII. It is the same which is now kittle-pins, in which boys often make use of bones instead of wooden pins, throwing at them with another bone instead of bowling.

Hamner.

Did these bones cost no more the breeding, but to play at *loggats* with them?

Shakspeare. Hamlet.

L O G I C.

LOGIC, *n. s.* } Fr. *logique*; Span. Port.
LOGICAL, *adj.* } and Lat. *logica*; Gr. *λογος*.
LOGICALLY, *adv.* } Reason; the art of reason-
LOGICIAN, *n. s.* } ing. Logical is pertaining
LOGOMACHY, *n. s.* } to, or skill in this art. Lo-
gician, a teacher, performer, or proficient in it;
logomachy, verbal contention.

The heretick complained greatly of St. Augustine, as being too full of *logical* subtleties. Hooker.

Talk *logick* with acquaintance,

And practise rhetorick in your common talk.

Shakspeare.

If a man can play the true *logician*, and have as well judgment as invention, he may do great matters.

Bacon.

By a *logick* that left no man any thing which he might call his own, they no more looked upon it as the case of one man, but the case of the kingdom.

Clarendon.

Forced terms of art did much puzzle sacred theology with distinctions, cavils, quiddities; and so transformed her to a mere kind of sophistry and *logomachy*.

Hewel.

In such manner easily, without uttering any *logical* untruth, one may yet grievously calumniate.

Barrow.

Logicians use to class a proposition,

As justices do criminals in prison,

And in as learned authentic nonsense writ

The names of all their modes and figures fit:

For a *logician's* one that has been broke

To ride and pace his reason by the book,

And by their rules, and precepts, and examples,

To put his wits in any kind of trammels. Butler.

Those who in a *logical* dispute keep in general terms, would hide a fallacy.

Dryden.

The application of whips, racks, gibbets, gallies, dungeons, fire and faggot, in a dispute, may be looked upon as popish refinements upon the old heathen *logic*.

Addison.

If we may believe our *logicians*, man is distinguished from all other creatures by the faculty of laughter.

Id.

How can her old good man

With honor take her back again?

From hence I *logically* gather,

The woman cannot live with either. Prior.

Here foamed rebellious *Logic*, gagged and bound,
There stript, fair Rhetorick languished on the ground.

Pope.

Each staunch polemick stubborn as a rock,

Each fierce *logician* still expelling Locke,

Came whip and spur. Id. Dunciad.

A *logician* might put a case that would serve for an exception.

Swift.

Logick is the art of using reason well in our enquiries after truth, and the communication of it to others.

Watts's *Logick*.

Add to these incentives to social life, my reputation for bookish knowledge, a certain wild *logical* talent, and a strength of thought, something like the rudiments of good sense; and it will not seem surprising that I was generally a welcome guest where I visited.

Burns.

Vociferated *logic* kills me quite,

A noisy man is always in the right—

I twirl my thumbs, fall back into my chair,

Fix on the wainscot a distressful stare,

And, when I hope his blunders are all out,

Reply discreetly—to be sure—no doubt! Couper.

But hold, my deign I to dispute

With such a scoundrel of a brute?

Logic is lost upon a knave,

Let action prove the law our slave. Beattie.

LOGIC, accurately defined, is the art of thinking and reasoning justly: it traces the progress of our knowledge from our first and most simple conceptions through all their different combinations, and all those numerous deductions that result from variously comparing them one with another.

The object of this science therefore is, to explain the nature of the human mind, and the proper manner of conducting its several powers, in order to attain truth and knowledge. It lays open those errors to which we are liable through inattention; and teaches us how to distinguish between truth and the appearance of it. By these means we become acquainted with the nature and power of the understanding; see what things lie within its reach; where we may attain certainty and demonstration; and when we must be contented with probability.

This science has been generally divided into four parts, viz. perception, judgment, reasoning, and method; which comprehend the whole operations of the Mind. The late professor Brown resolves judgment and reason into relative suggestion. See Lectures on the Philosophy of the Human Mind, vol. iii. lec. 51. He also supplies us with an able view of the rationale of logic, which the reader will find in a condensed form at the end of this paper.

PART I.

OF PERCEPTION.

Man is surrounded with a variety of objects, which, acting differently upon his senses, convey distinct impressions into the mind, and thereby

rouse the attention and notice of the understanding. By reflecting too on what passes within us, we become sensible of the operations of our own minds, and attend to them as a new set of impressions. But in all this there is only bare consciousness. The mind, without proceeding any farther, takes notice of the impressions that are made upon it, and views things in order as they present themselves one after another. This attention of the understanding to the objects acting upon it, whereby it becomes sensible of the impressions they make, is called by logicians perception; and the notices themselves, as they exist in the mind, and are there treasured up to be the materials of thinking and knowledge, are distinguished by the name of ideas. In the article *METAPHYSICS*, it will be shown at large how the mind, being furnished with ideas, contrives to diversify and enlarge its stock: we have here chiefly to consider the means of making known our thoughts to others; that we may not only understand how knowledge is acquired, but also in what manner it may be communicated with the greatest certainty and advantage.

SECT. I.—OF WORDS, CONSIDERED AS THE SIGNS OF IDEAS.

1. Our ideas, though manifold and various, being all within our own breasts, invisible to others, cannot of themselves be made to appear. But God, designing us for society, has provided us with organs fitted to frame articulate sounds, and has given us a capacity of using these sounds as signs of internal conceptions. Hence spring words and language: for, having once fixed upon any sound to stand as the mark of an idea in the mind, custom by degrees establishes such a connexion between them, that the appearance of the idea in the understanding always brings to our remembrance the sound or name by which it is expressed; as in like manner the hearing of the sound never fails to excite the idea for which it is made to stand. And thus it is easy to conceive how a man may record his own thoughts, and bring them again into view in any succeeding period of life. For this connexion being once settled, as the same sounds will always serve to excite the same ideas; if he can but register his words in the order and disposition in which the present train of his thoughts presents itself to his imagination, it is evident he will be able to recal his thoughts at pleasure, and that too in the very manner of their first appearance. Accordingly we find, that the inventions of writing and printing, by enabling us to fix and perpetuate such perishable things as sounds, have furnished us with the means of giving a kind of permanency to the transactions of the mind, so that they may be subjected to our review in the same manner as any other objects of nature.

2. But, besides the ability of recording our own thoughts, there is this farther advantage in the use of external signs, that they enable us to communicate our thoughts to others, and to receive information of what passes in their breasts. For any number of men, having agreed to establish the same sounds as signs of the same ideas, it is evident that the repetition of these sounds must excite the like perception in each, and

create a perfect correspondence of thoughts. When, for instance, any ideas succeed one another in my mind, if the names by which I am wont to express them have been annexed by those with whom I converse to the very same set of ideas, nothing is more evident than that, by repeating those names, according to the tenor of my present conceptions, I shall raise in their minds the same course of thought that has taken possession of my own. So that we here clearly perceive how a man may communicate his sentiments, knowledge, and discoveries to others, if the language in which he converses be extensive enough to mark all the ideas and operations of his mind. But as this is not always the case, and men are often obliged to invent terms of their own to express new views and conceptions of things; it may be asked, how in these circumstances we can become acquainted with the thoughts of another, when he makes use of words to which we have never annexed any ideas, and which of course can raise no perceptions in our minds? To unveil this mystery, and give some insight into the foundation, growth, and improvement of language, the following observations will be found of considerable moment.

3. First, that no word can be to any man the sign of an idea, till that idea comes to have a real existence in his mind. For names being only so far intelligible as they denote known internal conceptions, where they have none such to answer them, they are plainly sounds without signification, and of course convey no instruction or knowledge. But no sooner are the ideas to which they belong raised in the understanding, than, finding it easy to connect them with the established names, we can join in any agreement of this kind made by others, and thereby enjoy the benefit of their discoveries. The first thing therefore to be considered is, *how* these ideas may be excited in the mind; that, being there, we may learn to connect them with their appropriated sounds, and so become capable of understanding others, when they make use of these sounds in communicating their thoughts. To comprehend this distinctly, it will be necessary to attend to the division of our ideas into the simple and complex. And first, as for our simple ideas; they originate in sensation and reflexion. If therefore any of these have as yet no being in the understanding, it is impossible by words to excite them there. A man who had never felt the sensation of heat, could not be brought to comprehend that sensation by any thing we might say to explain it. If we would really produce the idea in him, it must be by applying the proper object to his senses, and bringing him within the influence of a hot body. When this is done, and experience has taught him the perception to which men have annexed the name heat, it then becomes to him the sign of that idea, and he thenceforth understands the meaning of the term, which, before, all the words in this world would not have been sufficient to convey into his mind. The case is the same in respect of light and colors. A man born blind, and thereby deprived of the only conveyance for ideas of this class, can never be brought to understand the names by which they are ex-

pressed. The reason is plain: they stand for ideas that have no existence in his mind; and, as the organ appropriated to their reception is wanting, all other contrivances are vain, nor can they by any force or description be raised in his imagination. But it is quite otherwise in our complex notions: for these being no more than certain combinations of simple ideas, put together in various forms; if the original ideas out of which the collections are made have already found admission into the understanding, and the names serving to express them are known; it will be easy, by enumerating the several ideas concerned in the composition, and marking the order and manner in which they are united, to raise any complex conception in the mind. Thus the idea answering to the word rainbow may be readily excited in the imagination of another who has never seen the appearance itself, by barely describing the figure, largeness, position, and order of colors; if we suppose these several simple ideas, with their names, sufficiently known to him.

4. This leads to a second observation upon this subject, namely, that words standing for complex ideas are all definable, but those by which we denote simple ideas are not; for simple ideas being perceptions, which have no other entrance into the mind than by sensation or reflection, can only be obtained by experience, from the several objects of nature proper to produce those perceptions in us. Words indeed may serve to remind us of them, if they have already found admission into the understanding, and if their connexion with the established names is known; but they can never give them their original being or existence there. Hence, when any one asks the meaning of a word denoting a simple idea, we pretend not to explain it to him by a definition, knowing that to be impossible; but, supposing him already acquainted with the idea, and only ignorant of the name by which it is called, we either mention it to him by some other name with which we presume he knows its connexion, or appeal to the object where the idea itself is found. Thus, were any man to ask the meaning of the word white, we should tell him it stood for the same idea as albus in Latin, or blanc in French; or, if we thought him a stranger to these languages, we might appeal to an object producing the idea, by saying it denoted the color we observe in snow or milk. But this is by no means a definition of the word, exciting a new idea in his understanding; but merely a contrivance to remind him of a known idea, and teach him its connexion with the established name. For if the ideas after which he enquires have never yet been raised in his mind; as suppose one, who had seen no other colors than black and white, should ask the meaning of the word scarlet; it is easy to perceive, that it would be no more possible to make him comprehend it by words, or by a definition, than to introduce the same perception into the imagination of a man born blind. The only method in this case is, to present some object, by looking at which the perception itself may be excited; and thus he will learn both the name and the idea together.

5. But how comes it to pass, that men agree in the names of their simple ideas, seeing they cannot view the perceptions in one another's minds, nor make known these perceptions by words to others? The effect is produced by experience and observation. Thus finding, for instance, that the name of heat is annexed to that sensation which men feel when they approach the fire, I make it also the sign of the sensation excited in me by such an approach, nor have any doubt but it denotes the same perception in my mind as in theirs. For we are naturally led to imagine, that the same objects operate alike upon the organs of the human body, and produce a uniformity of sensations. No man fancies that the idea raised in him by the taste of sugar, and which he calls sweetness, differs from that excited in another by the like means; or that wormwood, to whose relish he has given the epithet bitter, produces in another the sensation which he denotes by the word sweet. Presuming, therefore, upon this conformity of perceptions, when they arise from the same objects, we easily agree as to the names of our simple ideas: and if at any time, by a more narrow scrutiny into things, new ideas of this class come in our way, which we choose to express by terms of our own invention; these names are explained, not by a definition, but by referring to the objects whence the ideas themselves may be obtained.

6. Being in this manner furnished with simple ideas, and the names by which they are expressed, the meaning of terms that stand for complex ideas is easily acquired, because the ideas themselves answering to these terms may be conveyed into the mind by definitions. For our complex notions are only certain combinations of simple ideas. When, therefore, these are enumerated, and the manner in which they are united into one conception explained, nothing more is wanting to raise that conception in the understanding; and thus the term denoting it comes of course to be understood. And here it is worth while to reflect a little upon the wisdom and goodness of the Deity, in thus furnishing us with the very aptest means of communicating our thoughts. For were it not so ordered, that we could thus convey our complex ideas to one another by definitions, it would in many cases be impossible to make them known at all. This is apparent in those ideas which are the proper work of the mind. For as they exist only in the understanding, and have no real objects in nature in conformity to which they are framed; if we could not make them known by description, they must lie for ever hid within our own breasts, and be confined to the narrow limits of a single mind. All the fine scenes that arise from time to time in the poet's fancy, and, by his lively painting, give such entertainment to his readers; were he destitute of this faculty of laying them open to the view of others by words and description, could not extend their influence beyond his own imagination, or give joy to any but himself.

7. There is this additional advantage, in the ability we enjoy of communicating our complex notions by definitions; that as these make by far the largest class of our ideas, and most frequently occur in the progress and improvement

of knowledge, so they are by these means imparted with the greatest readiness, than which nothing would tend more to the increase and spreading of science: for a definition is soon examined; and, if the terms of it are well understood, the idea itself finds an easy admission into the mind. Whereas, in simple perceptions, where we are referred to the objects producing them, if these be not accessible, as is sometimes the case, the names by which they are expressed must remain empty sounds. But new ideas of this class occurring very rarely in the sciences, they seldom create any great obstructions. It is otherwise with our complex notions: for every step we take leading us into new combinations and views of things, it becomes necessary to explain these to others, before they can be made acquainted with our discoveries: and as the manner of defining is easy, requiring no apparatus but words, which are always ready, and at hand, we can with less difficulty remove such obstacles as might arise from terms of our own invention, when they are made to stand for new complex ideas suggested to the mind by some present train of thinking. And thus we see how we may become acquainted with the thoughts of another, when he makes use of words to which we have as yet joined no ideas. If the terms denote simple perceptions, he must refer us to those objects of nature whence the perceptions themselves are to be obtained; but, if they stand for complex ideas, their meaning may be explained by a definition.

SECT. II.—OF DEFINITIONS.

1. A definition is the unfolding of some conceptions of the mind, answering to the word or term made use of as its sign. Now as, in exhibiting any idea to another, it is necessary that the description be such as may excite that precise idea in his mind; it is plain that definitions, properly speaking, are not arbitrary, but confined to the representing of certain determinate settled notions, annexed by the speaker or writer to the words he uses. As, however, it is universally allowed, that the signification of words is perfectly arbitrary, and not the effect of any natural and necessary connexion between them and the ideas for which they stand; some may perhaps wonder why definitions are not so too. To unravel this difficulty, and show distinctly what is and what is not arbitrary in speech, we must carefully distinguish between the connexion of our words and ideas, and the unfolding of the ideas themselves.

2. First, as to the connexion of our words and ideas; this, it is plain, is purely arbitrary. When, for instance, we have in our minds the idea of any particular species of metals, our calling it by the name of gold is an effect of the voluntary choice of men speaking the same language, and not of any peculiar aptness in that sound to express that idea. Other nations we find make use of different sounds, and with the same effect. Thus *aurum* denotes that idea in Latin, and *or* in French; and even the word *gold* itself would have as well served to express the idea of that metal which we call silver, had custom in the beginning established it.

3. But, although we are thus entirely at liberty in connecting any idea with any sound, yet it is quite otherwise in unfolding the ideas themselves. For every idea having a precise appearance of its own, by which it is distinguished from every other idea; it is manifest that, in representing it to others, we must study such a description as shall exhibit that peculiar appearance. When we have formed the idea of a figure bounded by four equal sides, joined together at right angles, we may express that idea by any sound, and call it either a square or a triangle. But whichever of these names we use, so long as the idea is the same, the description by which we would signify it to another must be so too. Let it be called square or triangle, it is still a figure having four equal sides, and all its angles right ones. Hence we clearly see what is and what is not arbitrary in the use of words. The establishing of any sound, as the mark of some determinate idea in the mind, is the effect of free choice, and a voluntary combination among men: and, as different nations make use of different sounds to denote the same ideas, hence proceeds all that variety of languages which we meet with in the world. But, when a connexion between our ideas and words is once settled, the unfolding of the idea answering to any word, which properly constitutes a definition, is by no means an arbitrary thing: for here we are bound to exhibit that precise conception which either the use of language, or our own particular choice, has annexed to the term we use.

4. Thus it appears, that definitions, considered as descriptions of ideas in the mind, are steady and invariable, being bounded to the representation of these precise ideas. But then, in the application of definitions to particular names, we are altogether left to our own free choice; because, as the connecting of any idea with any sound is perfectly arbitrary, the applying the description of that idea to that sound must be so too. When, therefore, logicians tell us that the definition of the name is arbitrary, they mean no more than this; that as different ideas may be connected with any term, according to the good pleasure of him that uses it, so may different descriptions be applied to the term, suitable to the ideas thus connected. But this connexion being settled, and the term considered as the sign of some fixed idea in the understanding, we are no longer left to arbitrary explications, but must study such a description as corresponds with that precise idea. Now this alone, according to what has been before laid down, ought to be accounted a definition. What seems to have occasioned no small confusion in this matter, is, that many explanations of words, where no idea is unfolded, but merely the connexion between some word and idea asserted, have yet been dignified with the name of definitions. Thus, when we say that a clock is an instrument by which we measure time; that is by some called a definition: and yet it is plain that we are previously supposed to have an idea of this instrument, and only taught that the word *clock* serves in common language to denote that idea. By this rule all explications of words in our dictionaries will be definitions, nay, the names of

even simple ideas may be thus defined. White, we may say, is the color we observe in snow or milk; heat, the sensation produced by approaching the fire; and so in innumerable other instances. But these, and all others of the like kind, are by no means definitions, exciting new ideas in the mind, but merely contrivances to remind us of known ideas, and teach their connexion with the established names.

5. But now, in definitions properly so called, we first consider the term we use as the sign of some inward conception, either annexed to it by custom, or by our own free choice; and then the business of the definition is to unfold and explain that idea. As, therefore, the whole art lies in giving just and true copies of our ideas; a definition is then said to be perfect, when it serves distinctly to excite the idea described in the mind of another, even supposing him before wholly unacquainted with it. This point settled, let us next enquire what those ideas are which are capable of being thus unfolded? In the first place, it is evident, that all our simple ideas are necessarily excluded. We have seen that experience alone is to be consulted here, so that if either the objects whence they are derived come not in our way, or the avenues appointed by nature for their reception are wanting, no description is sufficient to convey them into the mind. But where the understanding is already supplied with these original and primitive conceptions, as they may be united together in an infinity of different forms, so may all their several combinations be distinctly laid open, by enumerating the simple ideas concerned in the various collections, and tracing the order and manner in which they are linked one to another. Now these combinations of simple notions constitute what we call our complex notions; whence it is evident, that complex ideas, and these alone, admit of that kind of description which goes by the name of a definition.

6. Definitions, then, are representations of our ideas; and, as these representations are possible only when the ideas themselves are complex, it is obvious, that definitions cannot have place but where we make use of terms standing for such complex ideas. But, our complex ideas being nothing more than different combinations of simple ideas, we then know and comprehend them perfectly, when we know the several simple ideas of which they consist, and can so put them together in our minds, as may be necessary towards the framing of that peculiar connexion which gives every idea its distinct and proper appearance.

7. Two things are therefore required in every definition: 1st, That all the original ideas, out of which the complex one is formed, be distinctly enumerated; and, 2dly, That the order and manner of combining them into one conception be clearly explained. Where a definition has these requisites, nothing is wanting to its perfection; because every one who reads it and understands the terms, seeing at once what ideas he is to join together, and also in what manner, can at pleasure form in his own mind the complex conception answering to the term defined. Let us, for instance, suppose the word square to stand for that idea by which we represent to ourselves a

figure whose sides subtend quadrants of a circumscribed circle. The parts of this idea are the sides bounding the figure. These must be four in number, and all equal among themselves, because they are each to subtend a fourth part of the same circle. But, besides these component parts, we must also take notice of the manner of putting them together, if we would exhibit the precise idea for which the word square here stands. For four equal right lines, anyhow joined, will not subtend quadrants of a circumscribed circle. A figure with this property must have its sides standing also at right angles. Taking in therefore this last consideration, respecting the manner of combining the parts, the idea is fully described, and the definition thereby rendered complete. For a figure bounded by four equal sides, joined together at right angles, has the property required; and is moreover the only right-lined figure to which that property belongs.

8. It will now be obvious to every one, in what manner we ought to proceed, in order to arrive at just and adequate definitions. 1st, We are to take an exact view of the idea to be described, trace it to its original principles, and mark the several simple perceptions that enter into its composition. 2dly, We are to consider the particular manner in which these elementary ideas are combined, in order to form that precise conception for which the term we make use of stands. When this is done, and the idea wholly unfolded, we have only to transcribe the appearance it makes to our own minds. Such a description, by distinctly exhibiting the order and number of our primitive conceptions, cannot fail to excite at the same time, in the mind of every one that reads it, the complex idea resulting from them; and therefore attains the true and proper end of a definition.

SECT. III.—OF THE COMPOSITION AND RESOLUTION OF OUR IDEAS, AND THE RULES OF DEFINITION THENCE ARISING.

1. The rule laid down in the last section is general, extending to all possible cases; and is indeed that to which alone we can have recourse where any doubt or difficulty arises. It is not, however, necessary that we should practise it in every case. Many of our ideas are extremely complicated, inasmuch that to enumerate all the simple perceptions, out of which they are formed, would be a very troublesome and tedious work. For this reason logicians have established certain compendious rules of defining, of which we shall give some account. But, for the better understanding of what follows, it is necessary to observe, that there is a certain gradation in the composition of our ideas. The mind of man is very limited in its views, and cannot take in a great number of objects at once. We must therefore proceed by steps, and make our first advances subservient to those which follow. Thus, in forming our complex notions, we begin at first with but a few simple ideas, such as we can manage with ease, and unite them together into one conception. When we are provided with a sufficient stock of these, and have by habit and use rendered them familiar to our minds, they become the component parts of other

ideas still more complicated, and form what we call a second order of compound notions. This process may be continued to any degree of composition we please, mounting from one stage to another, and enlarging the number of combinations.

2. But, in a series of this kind, whoever would acquaint himself perfectly with the last and highest order of ideas, finds it the most expedient method to proceed gradually through all the intermediate steps. For, were he to take any very compound idea to pieces, and, without regard to the several classes of simple perceptions that have already been formed into distinct combinations, break it at once into its original principles, the number would be so great as perfectly to confound the imagination, and overcome the utmost reach and capacity of the mind. When we see a prodigious multitude of men jumbled together in crowds, without order or any regular position, we find it impossible to arrive at an exact knowledge of their number. But if they are formed into separate battalions, and so stationed as to fall within the deliberate survey of the eye, by viewing them successively and in order, we come to an easy and certain determination. It is the same in our complex ideas. When the original perceptions, out of which they are framed, are very numerous, it is not enough that we take a view of them in loose and scattered bodies; we must form them into distinct classes, and unite these classes in a just and orderly manner, before we can arrive at a true knowledge of the compound notions resulting from them.

3. This gradual progress of the mind to its compound notions, through a variety of intermediate steps, plainly points out the manner of conducting the definitions by which these notions are conveyed into the minds of others. For as the series begins with simple and easy combinations, and advances through a succession of different orders, rising one above another in the degree of composition, it is evident that, in a train of definitions expressing these ideas, a like gradation is to be observed. Thus the complex ideas of the lowest order can no otherwise be described than by enumerating the simple ideas out of which they are made, and explaining the manner of their union. But then, in the second or any other succeeding order, as they are formed out of those gradual combinations, and constitute the inferior classes, it is not necessary, in describing them, to mention one by one all the simple ideas of which they consist. They may be more distinctly and briefly unfolded, by enumerating the compound ideas of a lower order, from whose union they result, and which are all supposed to be already known in consequence of previous definitions. Here then it is, that the logical method of defining takes place; which, that it may be the better understood, we shall explain somewhat more particularly the several steps and gradations of the mind in compounding its ideas, and thence deduce that peculiar form of a definition which logicians have thought fit to establish.

4. All the ideas we receive from the several objects of nature that surround us represent distinct individuals. These individuals, when com-

pared together, are found in certain particulars to resemble each other. Hence, by collecting the resembling particulars into one conception, we form the notion of a *species*. And here let it be observed, that this last idea is less complicated than that by which we represent any of the particular objects contained under it. For the idea of the species excludes the peculiarities of the several individuals, and retains only such properties as are common to them all. Again, by comparing several species together, and observing their resemblance, we form the idea of a *genus*; where, in the same manner as before, the composition is lessened, because we leave out what is particular to the several species compared, and retain only the particulars wherein they agree. It is easy to conceive the mind proceeding thus from one step to another, and advancing through its several classes of general notions, until at last it comes to the highest genus of all, denoted by the word *being*, where the bare idea of existence only is concerned.

5. In this procedure we see the mind unraveling a complex idea, and tracing it in the ascending scale, from greater or less degrees of composition, until it terminates in one simple perception. If now we take the series the contrary way, and, beginning with the last or highest genus, carry our view downward, through all the inferior genera and species, quite to the individuals, we shall thereby arrive at a distinct apprehension of the conduct of the understanding in compounding its ideas. For, in the several classes of our perceptions, the highest in the scale is for the most part made up of but a few simple ideas, such as the mind can take in and survey with ease. This first general notion, when branched out into the different subdivisions contained under it, has in every one of them something peculiar, by which they are distinguished among themselves; insomuch that, in descending from the genus to the species, we always superadd some new idea, and thereby increase the degree of composition. Thus the idea denoted by the word figure is of a very general nature, and composed of but few simple perceptions, as implying no more than space every where bounded. But if we descend farther, and consider the boundaries of this space, as that they may be either lines or surface, we distinguish the several species of figure. For, where the space is bounded by one or more surfaces, we give it the name of a solid figure; but, where the boundaries are lines, it is called a plain figure.

6. In this view of things it is evident, that the species is formed by superadding a new idea to the genus. Here, for instance, the genus is circumscribed space. If now to this we superadd the idea of a circumscription by lines, we frame the notion of that species of figures which are called plain; but, if we conceive the circumscription to be by surfaces, we have the species of solid figures. This superadded idea is called the specific difference, not only as it serves to divide the species from the genus, but because, being different in all the several subdivisions, we thereby also distinguish the species one from another. And as it is likewise that conception, which, by being joined to the general idea, completes the

notion of the species; hence it is plain, that the genus and specific difference are to be considered as the proper and constituent parts of the species. If we trace the progress of the mind still farther, and observe it advancing through the inferior species, we shall find its manner of proceeding to be always the same. For every lower species is formed by superadding some new idea to the species next above it; so that, in this descending scale of our perceptions, the understanding passes through different orders of complex notions, which become more and more complicated at every step it takes. Let us resume here, for instance, the species of plain figures. They imply no more than space bounded by lines. But if we take in an additional consideration of the nature of these lines, as whether they are right or curves, we refer to the subdivisions of plain figures, distinguished by the names of rectilinear, curvilinear, and mixtilinear.

7. And here we must observe, that though plain figures, when considered as one of those branches that come under the notion of figure in general, take the name of a species; yet, compared with the classes of curvilinear, rectilinear, and mixtilinear, into which they themselves may be divided, they really become a genus of which the above mentioned subdivisions constitute the several species. These species, in the same manner as in the case of plain and solid figures, consist of the genus and specific difference as their constituent parts. For, in the curvilinear kind, the curvity of the lines bounding the figure makes what is called the specific difference; to which if we join the genus, which here is a plain figure or space circumscribed by lines, we have all that is necessary towards completing the notion of this species. We are only to take notice that this last subdivision, having two genera above it, viz. plain figure, and figure in general, the genus joined with the specific difference, in order to constitute the species of curvilinears, is that which lies nearest to the said species. It is the notion of plain figure, and not of figure in general, that, joined with the idea of curvity, makes up the complex conception of curve-lined figures. For in this descending scale of our ideas, figure in general, plain figures, curve-lined figures, the first two are considered as general in respect of the third: and the second in order, or that which stands next to the third, is called the nearest genus. But now as it is this second idea, which, joined with the notion of curvity, forms the species of curve-lined figures, it is plain, that the third or last idea in the series is made up of the nearest genus and specific difference. This rule holds invariably however far the series is continued; because, in a train of ideas thus succeeding one another, all that precede the last are considered as so many genera in respect of that last, and the last itself is always formed by superadding the specific difference to the genus next it.

8. Here then we have a universal description, applicable to all our ideas of whatever kind, from the highest genus to the lowest species. For, taking them in order downwards from the said general idea, they every where consist of the genus proximum, and differentia specifica,

as logicians express them. But when we come to the lowest species of all, comprehending under it only individuals, the superadded idea by which these individuals are distinguished one from another no longer takes the name of the specific difference. For here it serves not to denote distinct species, but merely a variety of individuals, each of which, having a particular existence of its own, is therefore numerically different from every other of the same kind. And hence it is that, in this last case, logicians call the superadded idea by the name of the numeral difference, so that, as the idea of a species is made up of the nearest genus and specific difference, the idea of an individual consists of the lowest species and numeric difference. Thus the circle is a species of curve-lined figures, and what we call the lowest species as comprehending under it only individuals. Circles in particular are distinguished from one another by the length and position of their diameters. The length therefore and position of the diameter of a circle form what logicians call the numerical difference; because, these being given, the circle itself may be described, and an individual thereby constituted.

9. Thus the mind, in compounding its ideas, begins, we see, with the most general notions, which, consisting of but a few simple notices, are easily combined and brought together into one conception. Thence it proceeds to the species comprehended under this general idea, and these are formed by joining together the genus and specific difference. And as it often happens that these species may be still farther subdivided, and run on in a long series of continued gradations, producing various orders of compound perceptions, so all these several orders are regularly and successively formed by annexing in every step the specific difference to the nearest genus. When by this method of procedure we are come to the lowest order of all, by joining the species and numeric difference, we frame the ideas of individuals. And here the series necessarily terminates, because it is impossible any farther to bound or limit our conceptions. This view of the composition of our ideas, representing their constituent parts in every step of the progression, naturally points out the true and genuine form of a definition. For as definitions are merely descriptions of the ideas for which the terms defined stand, and as ideas are then described, when we enumerate distinctly the parts of which they consist, it is plain that, by making our definitions follow one another according to the natural train of our conceptions, they will be subject to the same rules, and keep pace with the ideas they describe.

10. As, therefore, the first order of our compound notions, or the ideas that constitute the highest genera in the different scales of perception, are formed by uniting together a certain number of simple notices, so the terms expressing these genera are defined by enumerating the simple notices so combined. And as the species comprehended under any genus, or the complex ideas of the second order, arise from superadding the specific difference to the said general idea, so the definition of the names of the

species consists in a detail of the ideas of the specific difference connected with the term of the genus. For, the genus having been before defined, the term by which it is expressed stands for a known idea, and may therefore be introduced into all subsequent definitions, in the same manner as the names of simple perceptions. It will now be sufficiently obvious, that the definitions of all the succeeding orders of compound notions will every where consist of the term of the nearest genus, joined with an enumeration of the ideas that constitute the specific difference; and that the definition of individuals unites the names of the lowest species with the terms by which we express the ideas of the numeric difference.

11. Here then we have the true and proper form of a definition, in all the various orders of conception. This is that method of defining which is commonly called *logical*, and which we see is perfect in its kind, as it presents a full and adequate description of the idea for which the term defined stands.

PART II. OF JUDGMENT.

SECT. I.—OF THE GROUNDS OF HUMAN JUDGMENT.

1. The mind being furnished with ideas, its next step in the way to knowledge is the comparing of these ideas together, in order to judge of their agreement or disagreement. In this joint view of our ideas, if the relation is such as to be immediately discoverable by the bare inspection of the mind, the judgments thence obtained are called *intuitive*, from a word that denotes to *look at*; for, in this case, a mere attention to the ideas compared suffices to let us see how far they are connected or disjointed. Thus, that the whole is greater than any of its parts, is an intuitive judgment; nothing more being required to convince us of its truth than an attention to the ideas of whole and part. And this too is the reason why we call the act of the mind forming these judgments *intuition*; as it is indeed no more than an immediate perception of the agreement or disagreement of any two ideas.

2. But here it is to be observed, that our knowledge of this kind respects only our ideas, and the relations between them; and therefore can serve only as a foundation to such reasonings as are employed in investigating those relations. Now it so happens, that many of our judgments are respecting facts, and the real existence of things, which cannot be traced by the bare contemplation of our ideas. It does not follow, because I have the idea of a circle in my mind, that therefore a figure answering to that idea has a real existence in nature. I can form to myself the notion of a centaur or golden mountain, but never imagine on that account that either of them exists. What then are the grounds of our judgment in relation to facts? Experience and testimony. By experience we are informed of the existence of the several objects which surround us, and operate upon our senses. Testimony is of a wider extent, and reaches not only to objects beyond the present

sphere of our observation, but also to such as could not without this conveyance have fallen under our cognizance.

3. Here we have three foundations of human judgment, from which the whole system of our knowledge may with ease and advantage be derived. First, intuition, which respects our ideas themselves, and their relations, and is the foundation of that species of reasoning which we call *demonstration*. For whatever is deduced from our intuitive perceptions, by a clear and connected series of proofs, is said to be demonstrated, and produces absolute certainty in the mind. Hence the knowledge obtained in this manner is what we properly term science; because in every step of the procedure it carries its own evidence along with it, and leaves no room for doubt or hesitation. And it is highly worthy of notice, that as the truths of this class express the relation between our ideas, and the same relations must ever and invariably subsist between the same ideas, our deductions in the way of science constitute what we call eternal, necessary, and immutable truths. If it be true that the whole is equal to all its parts, it must be so unchangeably; because the relation of equality, being attached to the ideas themselves, must ever intervene where the same ideas are compared. Of this nature are all the truths of natural religion, morality, and mathematics, and, in general, whatever may be gathered from the bare view and consideration of our ideas.

4. The second ground of human judgment is *experience*; from which we infer the existence of those objects which surround us, and fall under the immediate notice of our senses. When we see the sun, or turn our eyes towards a building, we not only have perceptions of these objects within ourselves, but ascribe to them a real existence out of the mind. It is also by the information of the senses, that we judge of the qualities of bodies; as when we say that snow is white, fire hot, steel hard. For, as we are wholly unacquainted with the internal structure and constitution of the bodies that produce these sensations in us, nay, are unable to trace any connexion between that structure and the sensations themselves, it is evident, that we build our judgments altogether upon observation, ascribing to bodies such qualities as are answerable to the perceptions they excite in us. Not that we ever suppose the qualities of bodies to be things of the same nature with our perceptions; for there is nothing in fire similar to our sensation of heat, or in a sword similar to pain; but that, when different bodies excite in our minds similar perceptions, we necessarily ascribe to these bodies not only an existence independent of us, but likewise similar qualities, of which it is the nature to produce similar perceptions in the human mind. But this is not the only advantage derived from experience; for to it also we are indebted for all our knowledge regarding the co-existence of sensible qualities in objects, and the operations of bodies one upon another. Ivory, for instance, is hard and elastic; this we know by experience, and indeed by that alone. For, being altogether strangers to the true nature both of elasticity

and hardness, we cannot by the bare contemplation of our ideas determine how far the one necessarily implies the other, or whether there may not be a repugnance between them. But, when we observe them to exist both in the same object, we are then assured from experience that they are not incompatible; and when we also find that a stone is hard and not elastic, and that air though elastic is not hard, we also conclude upon the same foundation, that the ideas are not necessarily conjoined, but may exist separately in different objects. In like manner, with regard to the mutual operations of bodies, it is evident that our knowledge is derived entirely from observation. Nitro-muriatic acid dissolves gold, as has been found by frequent trial, nor is there any other way of arriving at the discovery. Naturalists may tell us, if they please, that the parts of nitro-muriatic acid are of a texture apt to insinuate between the corpuscles of gold, and thereby loosen and shake them asunder. If this is a true account of the matter, it will notwithstanding be allowed, that our conjecture in regard to the conformation of these bodies is deduced from the experiment, and not the experiment from the conjecture. It was not from any previous knowledge of the intimate structure of nitro-muriatic acid and gold, and the aptness of their parts to act or be acted upon, that we arrived at the conclusion above mentioned. The internal constitution of bodies is wholly unknown to us; and, could we even surmount this difficulty, yet as the separation of the parts of gold implies something like an active force in the chemical agent, and we are unable to conceive how it comes to be possessed of this activity, the effect must be owned to be altogether beyond our comprehension. But when repeated trials had once confirmed it, so that it was admitted as an established truth, it was then easy for men to spin out theories of their own invention, and contrive such a structure of parts, both for gold and nitro-muriatic acid, as would best serve to explain the phenomenon upon the principles of that system of philosophy which they had adopted.

5. But, though experience is what we may term the immediate foundation of knowledge, yet with respect to particular persons its influence is very narrow and confined. The bodies that surround us are numerous, many of them lie at a great distance, and some quite beyond our reach. Life is so short, and so crowded with cares, that but little time is left for any single man to employ himself in unfolding the mysteries of nature. Hence it is necessary to admit many things upon the testimony of others, which thus becomes the foundation of a great part of our knowledge of body. No man doubts of the power of nitro-muriatic acid to dissolve gold, though perhaps he never himself made the experiment. In these therefore, and such cases, we judge of the facts and operations of nature upon the mere ground of testimony. However, as we can always have recourse to experience where any doubt or scruple arises, this is justly considered as the true foundation of natural philosophy; being indeed the ultimate support on which our assent rests, and to which we appeal when the highest degree of evidence is required.

6. But there are many facts that will not allow of an appeal to the senses; and in this case testimony is the true and only foundation of our judgments. All human actions of whatever kind, when considered as already past, are of the nature here described; because, having now no longer any existence, both the facts themselves, and the circumstances attending them, can be known only from the relations of such as had sufficient opportunities of arriving at the truth. *Testimony* therefore is justly accounted a third ground of human judgment; and as from the other two we have deduced scientific knowledge, so we may from this derive historical; by which we mean, not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatever, concerning which testimony is the sole foundation of our belief.

SECT. II.—OF AFFIRMATIVE AND NEGATIVE PROPOSITIONS.

1. While the comparing of our ideas is considered merely as an act of the mind, assembling them together, and joining or disjoining them according to the result of its perceptions, we call it judgment; but, when our judgments are put into words, they then bear the name of propositions. A proposition therefore is a sentence expressing some judgment of the mind, whereby two or more ideas are affirmed to agree or disagree. Now, as our judgments include at least two ideas, one of which is affirmed or denied of the other, so must a proposition have terms answering to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the subject of the proposition. The idea affirmed or denied, as also the term answering it, is called the predicate. Thus in the proposition, God is omnipotent: God is the subject, it being of him that we affirm omnipotence; and omnipotent is the predicate, because we affirm the idea expressed by that word to belong to God.

2. But as, in propositions, ideas are either joined or disjoined, it is not enough to have terms expressing those ideas unless we have also some words to denote their agreement or disagreement. That word in a proposition which connects two ideas together is called the copula; and, if a negative particle be annexed, we thereby understand that the ideas are disjoined. The substantive verb is commonly made use of for the copula, as in the above-mentioned proposition, God is omnipotent: where it represents the copula, and signifies the agreement of the ideas of God and omnipotence. But, if we mean to separate two ideas, then, besides the substantive verb, we must also use some particle of negation to express this repugnance. The proposition, Man is not perfect, may serve as an example of this kind; where, the notion of perfection being removed from the idea of man, the negative particle *not* is inserted after the copula, to signify the disagreement between the subject and predicate.

3. Every proposition necessarily consists of these three parts: but then it is not alike needful that they be all severally expressed in words; because the copula is often included in the term of the predicate, as when we say, he sits; which imports the same as, he is sitting. In the Latin

language, a single word has often the force of a whole sentence. Thus *ambulat* is the same as *Ille est ambulans*; *amo*, as *ego sum amans*; and so in innumerable other instances: by which it appears, that we are not so much to regard the number of words in a sentence, as the ideas they represent, and the manner in which they are put together. For whenever two ideas are joined or disjoined in an expression, though of but a single word, it is evident that we have a subject, predicate, and copula, and of consequence a complete proposition.

4. When the mind joins two ideas, we call it an *affirmative* judgment; when it separates them, a *negative*; and, as any two ideas compared together must necessarily either agree or not agree, it is evident that all our judgments fall under these two divisions. Hence likewise the propositions expressing these judgments are all either affirmative or negative. An affirmative proposition connects the predicate with the subject, as, a stone is heavy; a negative proposition separates them, as, God is *not* the author of evil. Affirmation therefore is the same as joining two ideas together, and this is done by means of the copula. Negation, on the contrary, marks a repugnance between the ideas compared; in which case a negative particle must be called in, to show that the connexion included in the copula does not take place.

5. Hence we see the reason of the rule commonly laid down by logicians, That, in all negative propositions, the negation ought to affect the copula. For as the copula, when placed by itself, between the subject and the predicate, manifestly binds them together, it is evident that, to render a proposition negative, the particles of negation must enter it in such a manner as to destroy this union. In a word, then only are two ideas disjoined in a proposition, when the negative particle may be so referred to the copula as to break the affirmation included in it, and undo that connexion it would otherwise establish. When we say, for instance, No man is perfect, take away the negation, and the copula of itself plainly unites the ideas in the proposition. But, as this is the very reverse of what is intended, a negative mark is added, to show that this union does not here take place. The negation, therefore, by destroying the effect of the copula, changes the very nature of the proposition, inasmuch that, instead of binding two ideas together, it denotes their separation. On the contrary, in this sentence, The man who departs not from an upright behaviour is beloved of God; the predicate, beloved of God, is evidently affirmed of the subject an upright man: so that, notwithstanding the negative particle, the proposition is still affirmative. The reason is plain: the negation here affects not the copula, but, making properly a part of the subject, serves, with other terms in the sentence, to form one complex idea, of which the predicate, beloved of God, is directly affirmed.

SECT. III.—OF UNIVERSAL AND PARTICULAR PROPOSITIONS.

1. The next considerable division of propositions is into universal and particular. Our

ideas, according to what has been already observed in the first part, are all singular as they enter the mind, and represent individual objects. But as by abstraction we can render them universal, so as to comprehend a whole class of things, and sometimes several classes at once; hence the terms expressing these ideas must be in like manner universal. If, therefore, we suppose any general term to become the subject of a proposition, it is evident that whatever is affirmed of the abstract idea, belonging to that term, may be affirmed of all the individuals to which that idea extends. Thus, when we say, men are mortal; we consider mortality, not as confined to one or any number of particular men, but as what may be affirmed without restriction of the whole species. Thus the proposition becomes as general as the idea which makes the subject of it; and indeed derives its universality entirely from that idea, being more or less so, according as this may be extended to more or fewer individuals. But it is further to be observed of these general terms, that they sometimes enter a proposition in their full latitude, as in the example given above; and sometimes appear with a mark of limitation. In this last case we are given to understand, that the predicate agrees not to the whole universal idea, but only to a part of it; as in the proposition, Some men are wise: for here wisdom is not affirmed of every particular man, but restrained to a few of the human species.

2. From this different appearance of the general idea, that constitutes the subject of any judgment, arises the division of propositions into universal and particular. A *universal* proposition is that wherein the subject is some general term taken in its full latitude; inasmuch that the predicate agrees to all the individuals comprehended under it, if it denotes a proper species; and to all the several species and their individuals, if it marks an idea of a higher order. The words all, every, no, none, &c., are the proper signs of this universality; and, as they seldom fail to accompany general truths, so they are the most obvious criterion whereby to distinguish them. All animals have a power of beginning motion. This is a universal proposition; as we know from the word *all* prefixed to the subject *animals*, which denotes that it must be taken in its full extent. Hence the power of beginning motion may be affirmed of all the several species of animals.

3. A *particular* proposition has in like manner some general term for its subject; but with a mark of limitation added, to denote that the predicate agrees only to some of the individuals comprehended under a species, or to one or more of the species belonging to any genus, and not to the whole universal idea. Thus, Some stones are heavier than iron; Some men have an uncommon share of prudence. In the latter of these propositions, the subject, some men, implies only a certain number of individuals, comprehended under a single species. In the former, where the subject is a genus that extends to a great variety of distinct classes, some stones may not only imply any number of particular stones, but also several whole species of stones, inasmuch as there may be not a few with the property there

described. Hence we see that a proposition does not cease to be particular by the predicate's agreeing to a whole species, unless that species, singly and distinctly considered, makes also the subject of which we affirm or deny.

4. There is still one species of propositions that remains to be described, and which the more deserves our notice as it is not yet agreed among logicians, to which of the two classes mentioned above they ought to be referred; namely, singular propositions, or those where the subject is an individual. Of this nature are the following:—Sir Isaac Newton was the inventor of fluxions; This book contains many useful truths. There is some difficulty as to the proper rank of these propositions, because, the subject being taken according to the whole of its extension, they sometimes have the same effect in reasoning as universals. But if it be considered that they are in truth the most limited kind of particular propositions, and that no proposition can with any propriety be called universal but where the subject is some universal idea, we shall not be long in determining to which class they ought to be referred. When we say some books contain useful truths; the proposition is particular, because the general term appears with a mark of restriction. If, therefore, we say, This book contains useful truths; it is evident that the proposition must be still more particular, as the limitation applied in the word *this* is of a more confined nature than in the former case.

5. We see, therefore, that all propositions are either affirmative or negative; nor is it less evident that, in both cases, they may be universal or particular. Hence arises that celebrated fourfold division of them into universal affirmative and universal negative, particular affirmative and particular negative, which comprehends indeed all their varieties. The use of this method of distinguishing them will appear more fully afterwards, when we come to treat of reasoning and syllogism.

SECT. IV. — OF ABSOLUTE AND CONDITIONAL PROPOSITIONS.

1. The objects about which we are chiefly conversant in this world are all of a nature liable to change. What may be affirmed of them at one time, cannot often be affirmed at another; and it makes no small part of our knowledge to distinguish rightly these variations, and trace the reasons on which they depend. For it is observable that, amidst all the vicissitude of nature, some things remain constant and invariable; nor even are the changes, to which we see others liable, effected but in consequence of uniform and steady laws, which, when known, are sufficient to direct us in our judgments respecting them. Hence philosophers, in distinguishing the objects of our perception into various classes, have been very careful to note, that some properties belong essentially to the general idea, so as not to be separable from it but by destroying its very nature; while others are only accidental, and may be affirmed or denied of it in different circumstances. Thus solidity, a yellow color, and great weight, are considered as essential qualities of gold; but whether it shall exist as a

uniform conjoined mass, is not alike necessary. We see that by a certain process it may be reduced to a fine powder, and that an intense heat will bring it into a state of fusion.

2. From this diversity in the several qualities of things arises a considerable difference as to the manner of our judging concerning them. For all such properties as are inseparable from objects, when considered as belonging to any genus or species, are affirmed absolutely and without reserve of that general idea. Thus we say, Gold is very weighty; a stone is hard; animals have a power of self-motion. But in the case of mutual or accidental qualities, as they depend upon some other consideration distinct from the general idea, that also must be taken into the account, in order to form an accurate judgment. Should we affirm, for instance, of some stones, that they are very susceptible of a rolling motion; the proposition, while it remains in this general form, cannot with any advantage be introduced into our reasonings. An aptness to receive that mode of motion flows from the figure of the stone; which, as it may vary infinitely, our judgment then only becomes applicable and determinate, when the particular figure, of which volubility is a consequence, is also taken into the account. Let us, then, bring in this other consideration, and the proposition will run as follows: stones of a spherical form are easily put into a rolling motion. Here we see the condition upon which the predicate is affirmed, and therefore know in what particular cases the proposition may be applied.

3. This consideration of propositions, respecting the manner in which the predicate is affirmed of the subject, gives rise to the division of them into absolute and conditional. *Absolute* propositions are those wherein we affirm some property inseparable from the idea of the subject, and which therefore belongs to it in all possible cases: as, God is infinitely wise; virtue tends to the ultimate happiness of man. But where the predicate is not necessarily connected with the idea of the subject, unless upon some consideration distinct from that idea, there the proposition is called *conditional*. The reason is from the supposition annexed, which is of the nature of a condition, and may be expressed as such, thus: If a stone is exposed to the rays of the sun, it will contract some degree of heat; if a river runs in a very declining channel, its rapidity will constantly increase.

4. There is not any thing of greater importance in philosophy than a due attention to this division of propositions. If we are careful never to affirm things absolutely but where the ideas are inseparably conjoined, and if in our other judgments we distinctly mark the conditions which determine the predicate to belong to the subject, we shall be less liable to mistake in applying general truths to the particular concerns of human life. It is owing to the exact observance of this rule that mathematicians have been so happy in their discoveries, and that what they demonstrate of magnitude in general may be applied with ease in all obvious occurrences.

5. The truth of it is, particular propositions are then known to be true, when we can trace

their connexion with universals; and it is accordingly the great business of science to find out general truths that may be applied with safety in all obvious instances. Now the great advantage arising from determining with care the conditions upon which one idea may be affirmed or denied of another is this: that thereby particular propositions really become universal, may be introduced with certainty into our reasonings, and serve as standards to conduct and regulate our judgments. To illustrate this by a familiar instance: if we say, some water acts very forcibly; the proposition is particular: and, as the conditions on which this forcible action depends are not mentioned, it is as yet uncertain in what cases it may be applied. Let us then supply these conditions, and the proposition will run thus: Water, conveyed in sufficient quantity along a steep descent, acts very forcibly. Here we have a universal judgment, inasmuch as the predicate forcible action may be ascribed to all water under the circumstances mentioned. Nor is it less evident that the proposition in this new form is of easy application; and in fact we find that men do apply it in instances where the forcible action of water is required; as in corn-mills and many other works of art.

SECT. V.—OF SIMPLE AND COMPOUND PROPOSITIONS.

1. Hitherto we have treated of propositions, where only two ideas are compared together. These are in the general called *simple*; because, having but one subject and one predicate, they are the effect of a simple judgment that admits of no subdivision. But if several ideas offer themselves to our thoughts at once, whereby we are led to affirm the same thing of different objects, or different things of the same object, the propositions expressing these judgments are called *compound*; because they may be resolved into as many others as there are subjects or predicates in the whole complex determination of the mind. Thus, God is infinitely wise and infinitely powerful. Here there are two predicates, infinite wisdom and infinite power, both affirmed of the same subject; and accordingly the proposition may be resolved into two others, affirming these predicates severally. In like manner, in the proposition, Neither kings nor people are exempt from death; the predicate is denied of both subjects, and may therefore be separated from them in distinct propositions. Nor is it less evident that, if a complex judgment consists of several subjects and predicates, it may be resolved into as many simple propositions as are the number of different ideas compared together. Riches and honors are apt to elate the mind, and increase the number of our desires. In this judgment there are two subjects and two predicates, and it is at the same time apparent that it may be resolved into four distinct propositions. Riches are apt to elate the mind. Riches are apt to increase the number of our desires. And so of honors.

2. Logicians have divided these compound propositions into many different classes; but not with a due regard to their proper definition. Thus conditionals, causals, relatives, &c., are

mentioned as so many distinct species of this kind, though in fact they are merely simple propositions. To give an instance of a conditional: If a stone is exposed to the rays of the sun, it will contract some degree of heat. Here we have but one subject and one predicate; for the complex expression, a stone exposed to the rays of the sun, constitutes the proper subject of this proposition, and is no more than one determined idea. The same thing happens in causals. Rehoboam was unhappy because he followed evil counsel. There is here an appearance of two propositions arising from the complexity of the expression; but, when we consider the matter more attentively, it is evident that we have but a single subject and predicate. The pursuit of evil counsel brought misery upon Rehoboam. It is not enough, therefore, to render a proposition compound, that the subject and predicate are complex notions, requiring sometimes a whole sentence to express them; for in this case the comparison is still confined to two ideas, and constitutes what we call a simple judgment. But where there are several subjects or predicates, or both, as the affirmation or negation may be alike extended to them all, the proposition expressing such a judgment is truly a collection of as many simple ones as there are different ideas compared. Confining ourselves therefore to this more strict and just notion of compound propositions, they are all reducible to two kinds, viz. copulatives and disjunctives.

3. A *copulative* proposition is, where the subjects and predicates are so linked together, that they may be all severally affirmed or denied one of another. Of this nature are the examples of compound propositions given above. 'Riches and honors are apt to elate the mind, and increase the number of our desires.' 'Neither kings nor people are exempt from death. In the first of these the two predicates may be affirmed severally of each subject, whence we have four distinct propositions. The other furnishes an example of the negative kind, where the same predicate, being disjoined from both subjects, may be also denied of them in separate propositions.

4. The other species of compound propositions are those called *disjunctives*; in which, comparing several predicates with the same subject, we affirm that one of them necessarily belongs to it, but leave the particular predicate undetermined. If any one, for example, says, 'This world either exists of itself, or is the work of some all-wise and powerful cause'; it is evident that one of the two predicates must belong to the world; but, as the proposition determines not which, it is therefore of the kind we call disjunctive. Such too are the following: 'The sun either moves round the earth, or is the centre about which the earth revolves.' 'Friendship finds men equal, or makes them so.' It is the nature of all propositions of this class, supposing them to be exact in point of form, that, upon determining the particular predicate, the rest are of course to be removed; or, if all the predicates but one are removed, that one necessarily takes place. Thus, in the example given above, if we allow the world to be the work of some wise and

powerful cause, we of course deny it to be self-existent; or, if we deny it to be self-existent, we must necessarily admit that it was produced by some wise and powerful cause. Now this particular manner of linking the predicates together, so that the establishing one displaces all the rest, or the excluding all but one necessarily establishes that one, cannot otherwise be effected than by means of disjunctive particles. And hence propositions of this class take their names from these particles which make so necessary a part of them, and indeed constitute their very nature considered as a distinct species

SECT. VI.—OF THE DIVISION OF PROPOSITIONS INTO SELF-EVIDENT AND DEMONSTRABLE.

1. When any proposition is offered to the view of the mind, if the terms in which it is expressed be understood, upon comparing the ideas together, the agreement or disagreement asserted is either immediately perceived, or found to lie beyond the present reach of the understanding. In the first case, the proposition is said to be *self-evident*, and admits not of any proof, because a bare attention to the ideas themselves produces full conviction and certainty; nor is it possible to call in any thing more evident by way of confirmation. But, where the connexion or repugnance comes not so readily under the inspection of the mind, there we must have recourse to reasoning; and if by a clear series of proofs we can make out the truth proposed, so that self-evidence shall accompany every step of the procedure, we are then able to demonstrate what we assert, and the proposition itself is said to be *demonstrable*. When we affirm, for instance, that 'it is impossible for the same thing to be and not to be;' whoever understands the terms made use of perceives at first glance the truth of what is asserted, nor can he by any efforts bring himself to believe the contrary. The proposition therefore is self-evident, and such that it is impossible by reasoning to make it plainer; because there is no truth more obvious or better known, from which as a consequence it may be deduced. But if we say, this world had a beginning; the assertion is indeed equally true, but shines not forth with the same degree of evidence. We find great difficulty in conceiving how the world could have a beginning: and are not brought to a free and full consent, until by reasoning we arrive at a clear view of the absurdity involved in the contrary supposition. Hence this proposition is of the kind we call *demonstrable*, as its truth is not immediately perceived by the mind, but yet may be made to appear by means of others more obvious, whence it follows as an unavoidable consequence.

2. From what has been said, it appears, that reasoning is employed only about demonstrable propositions, and that our intuitive or self-evident perceptions are the foundation on which it rests.

3. Self-evident propositions furnish the first principles of reasoning; and it is certain, that if in our researches we employ only such principles as have the character of self-evidence, and apply them according to the rules to be afterwards explained, we shall be in no danger of error in

advancing from one discovery to another. For this we may appeal to the writings of the mathematicians, which, being conducted by the express model here mentioned, are an incontestable proof of the firmness and stability of human knowledge, when built upon so sure a foundation. For not only have the propositions of this science stood the test of ages, but are found attended with that invincible evidence, which forces the assent of all who duly consider the proofs upon which they are established. Since the mathematicians are universally allowed to have adopted the right method of arriving at unknown truths, and have been the happiest in the choice as well as in the application of their principles, it may not be amiss to explain here their method of stating self-evident propositions, and applying them to the purposes of demonstration.

4. First then, it is to be observed, that they have been very careful in ascertaining their ideas and fixing the signification of their terms. For this purpose they begin with definitions, in which the meaning of their words is so distinctly explained, that they cannot fail to excite in the mind of an attentive reader the very same ideas that are annexed to them by the writer. And indeed the clearness and irresistible evidence of mathematical knowledge is owing to nothing so much as to this care in laying the foundation. Where the relation between any two ideas is accurately and justly traced, it will not be difficult for another to comprehend that relation, if in setting himself to discover it he brings the very same ideas into comparison. But if, on the contrary, he affixes to his words ideas different from those that were in the mind of him who first advanced the demonstration; it is evident that, as the same ideas are not compared, the same relation cannot subsist, so that a proposition will be rejected as false, which, had the terms been rightly understood, must have appeared incontestably true. A square, for instance, is a figure bounded by four equal right lines, joined together at right angles. Here the nature of the angles makes no less a part of the idea than the equality of the sides; and many properties demonstrated of the square flow entirely from its being a rectangular figure. If, therefore, we suppose a man, who has formed a partial notion of a square, comprehending only the equality of its sides, without regard to the angles, reading some demonstration that implies also this latter consideration; it is plain he would reject it as not universally true, as it could not be applied where the sides were joined together at equal angles. For this last figure, answering still to his idea of a square, would be yet found without the property assigned to it in the proposition. But, if he comes afterwards to correct his notion, he will then readily own the truth and justness of the demonstration.

5. We see, therefore, that nothing contributes so much to the improvement and certainty of human knowledge as having determinate ideas, and keeping them steadily and invariably in all our discourses and reasonings. On this account mathematicians always begin by defining their terms, and distinctly unfolding the notions they are intended to express. Hence such as apply

themselves to these studies have exactly the same views of things; and, bringing always the very same ideas into comparison, readily discern the relation between them. It is likewise of importance, in every demonstration, to express the same idea invariably by the same word. From this practice mathematicians never deviate; and if it be necessary in their demonstrations, where the reader's comprehension is aided by a diagram, it is much more so in all reasonings about moral or intellectual truths, where the ideas cannot be represented by a diagram. The observation of this rule may sometimes be productive of ill-sounding periods; but, when truth is the object, sound ought to be disregarded.

6. When the mathematicians have taken this first step, and made known the ideas whose relations they intend to investigate; their next care is, to lay down some self-evident truths, which may serve as a foundation for their future reasonings. And here indeed they proceed with remarkable circumspection, admitting no principles but such as flow immediately from their definitions, and necessarily force themselves upon a mind in any degree attentive to its ideas. Thus a circle is a figure formed by a right line moving round some fixed point in the same plane. The fixed point round which the line is supposed to move, and where one of its extremities terminates, is called the centre of the circle. The other extremity, which is conceived to be carried round until it returns to the point whence it first set out, describes a curve running into itself, and termed the circumference. All right lines drawn from the centre to the circumference are called radii. From these definitions compared, geometers derive this self-evident truth, 'that the radii of the same circle are all equal to one another.'

7. We now observe, that, in all propositions, we either affirm or deny some property of the idea that constitutes the subject of our judgment, or we maintain that something may be done or effected. The first sort are called speculative propositions, as in the example mentioned above, 'The radii of the same circle are all equal one to another.' The others are called practical, for a reason quite obvious; thus, that a right line may be drawn from one point to another, is a practical proposition, inasmuch as it expresses that something may be done.

8. From this twofold consideration of propositions arises the twofold division of mathematical principles into axioms and postulates. By an axiom they understand any self-evident speculative truth; as, 'That the whole is greater than its parts:' 'That things equal to one and the same thing are equal to one another.' But a self-evident practical proposition is what they call a postulate. Such are those of Euclid: 'That a finite right line may be continued directly forwards;' 'That a circle may be described about any centre with any distance.' And here we are to observe, that, as in an axiom the agreement or disagreement between the subject and predicate must come under the immediate inspection of the mind, so in a postulate, not only the possibility of the thing asserted must be evident at first view, but also the manner in which it may

be effected. For, where this manner is not of itself apparent, the proposition comes under the notion of the demonstrable kind, and is treated as such by geometrical writers. Thus, 'to draw a right line from one point to another,' is assumed by Euclid as a postulate, because the manner of doing it is so obvious, as to require no previous teaching. But then it is not equally evident, how we are to construct an equilateral triangle. For this reason he advances it as a demonstrable proposition, lays down rules for the exact performance, and at the same time proves, that, if these rules are followed, the figure will be justly described.

9. This leads us to notice, that as self-evident truths are distinguished into different kinds, according as they are speculative or practical, so is it also with demonstrable propositions. A demonstrable speculative proposition is by mathematicians called a theorem. Such is the famous forty-seventh proposition of the first book of the Elements, known by the name of the Pythagorean theorem, from its supposed inventor Pythagoras, viz. 'That, in every right-angled triangle, the square described upon the side subtending the right angle is equal to both the squares described upon the sides containing the right angle.' On the other hand, a demonstrable practical proposition is called a problem; as where Euclid teaches us to describe a square upon a given right line.

10. Besides the four kinds of propositions already mentioned, mathematicians have also a fifth, known by the name of corollaries. These are usually subjoined to theorems or problems, and differ from them only in this, that they flow from what is there demonstrated in so obvious a manner as to discover their dependence upon the proposition whence they are deduced, almost as soon as proposed. Thus Euclid having demonstrated, 'that in every right-lined triangle all the three angles taken together are equal to two right angles,' adds, by way of corollary, 'that all the three angles of any one triangle taken together are equal to all the three angles of any other triangle taken together:' which is evident at first sight; because in all cases they are equal to two right ones, and things equal to one and the same thing are equal to one another.

11. The scholia of mathematicians are indifferently annexed to definitions, propositions, or corollaries; and answer the same purposes as annotations upon a classic author. For in them occasion is taken to explain whatever may appear intricate and obscure in a train of reasoning; to answer objections; to teach the application and uses of propositions; to lay open the original and history of the several discoveries made in the science; and, in a word, to acquaint us with all such particulars as deserve to be known, whether considered as points of curiosity or profit.

PART III.

OF REASONING.

SECT. I.—OF REASONING IN GENERAL, AND THE PARTS OF WHICH IT CONSISTS.

1. It often happens, in comparing ideas together, that their agreement or disagreement cannot

be discerned at first view, especially if they are of such a nature as not to admit of an exact application one to another. When, for instance, we compare two figures of a different make, in order to judge of their equality or inequality, it is plain that, by barely considering the figures themselves, we cannot arrive at an exact determination; because, by reason of their disagreeing forms, it is impossible to put them together, so that their several parts shall mutually coincide. Here then it becomes necessary to look out for some third idea that will admit of such an application as the present case requires; wherein if we succeed, all difficulties vanish, and the relation we are in quest of may be traced with ease. Thus right-lined figures are all reduced to squares, by means of which we can measure their areas, and determine exactly their agreement or disagreement in point of magnitude.

2. But how can any third idea serve to discover a relation between two others? The answer is, by being compared severally with these others; for such a comparison enables us to see how far the ideas with which this third is compared are connected or disjoined between themselves. In the example mentioned above of two right-lined figures, if we compare each of them with some square whose area is known, and find the one exactly equal to it, and the other less by a square inch, we immediately conclude that the area of the first figure is a square inch greater than that of the second. The manner of determining the relation between any two ideas, by the intervention of some third with which they may be compared, is that which we call *reasoning*; and is indeed the chief instrument by which we push on our discoveries, and enlarge our knowledge. The great art lies in finding out such intermediate ideas, as, when compared with the others in the question, will furnish evident and known truths; because, as will afterwards appear, it is only by means of them that we arrive at the knowledge of what is hidden and remote.

3. Hence it appears, that every act of reasoning necessarily includes three distinct judgments; two wherein the ideas whose relation we want to discover are severally compared with the middle idea, and a third wherein they are themselves connected or disjoined, according to the result of that comparison. Now, as in the second part of logic our judgments, when put into words, were called propositions, so here in the third part the expressions of our reasonings are termed syllogisms. Hence it follows, that as every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. When a reasoning is thus put into words, and appears in form of a syllogism, the intermediate idea, made use of to discover the agreement or disagreement we search for, is called the middle term; and the two ideas themselves, with which this third is compared, go by the name of the extremes.

4. But as these things are best illustrated by examples; let us, for instance, set ourselves to enquire whether men are accountable for their actions. As the relation between the ideas of men and accountableness comes not within the immediate view of the mind, our first care must

be to find out some third idea that will enable us the more easily to discover and trace it. A very small measure of reflection is sufficient to inform us, that no creature can be accountable for his actions, unless we suppose him capable of distinguishing the good from the bad; that is, unless we suppose him possessed of reason. Nor is this alone sufficient. For what would it avail him to know good from bad actions, if he had no freedom of choice, nor could avoid the one and pursue the other? Hence it becomes necessary to take in both considerations in the present case. It is at the same time equally apparent, that wherever there is this ability of distinguishing good from bad actions, and of pursuing the one and avoiding the other, there also a creature is accountable. We have then obtained a third idea, with which accountableness is inseparably connected, viz. reason and liberty; which are here to be considered as making up one complex conception. Let us now take this middle idea, and compare it with the other term in the question, viz. man, and we all know by experience that it may be affirmed of him. Having thus by means of the intermediate idea formed two several judgments, viz. that man is possessed of reason and liberty; and that reason and liberty imply accountableness; a third obviously and necessarily follows, viz. that man is accountable for his actions. Here then we have a complete act of reasoning, in which, according to what has been already observed, there are three distinct judgments: two that may be styled previous, inasmuch as they lead to the other, and arise from comparing the middle idea with the two ideas in the question; the third is a consequence of these previous acts, and flows from combining the extreme ideas. If now we put this reasoning into words, it exhibits what logicians term a syllogism: and when proposed in due form runs thus:—‘Every creature possessed of reason and liberty is accountable for his actions.—Man is a creature possessed of reason and liberty;—Therefore man is accountable for his actions.’

5. In this syllogism we may observe, that there are three several propositions expressing the three judgments implied in the act of reasoning; and so disposed as to represent distinctly what passes within the mind in tracing the more distant relations of its ideas. The first two propositions answer the two previous judgments in reasoning, and are called the premises, because they are placed before the other. The third is termed the conclusion, as being gained in consequence of what was asserted in the premises. We are also to remember, that the terms expressing the two ideas whose relations we enquire after, as here man and accountableness, are in general called the extremes; and that the intermediate idea, by means of which the relation is traced, viz. a creature possessed of reason and liberty, takes the name of the middle term. Hence it follows, that by the premises of a syllogism we are always to understand the two propositions where the middle term is respectively compared with the extremes; for these constitute the previous judgments, whence the truth we are in quest of is by reasoning deduced. The conclusion is that other

proposition, in which the extremes themselves are joined or separated agreeably to what appears upon the above comparison.

6. The conclusion is made up of the extreme terms of the syllogism : and the extreme, which serves as the predicate of the conclusion, goes by the name of the major term : the other extreme, which makes the subject in the same proposition, is called the minor term. From this distinction of the extremes arises also a distinction between the premises, where these extremes are respectively compared with the middle term. That proposition which compares the greater extreme, or the predicate of the conclusion, with the middle term, is called the major proposition : the other, wherein the same middle term is compared with the subject of the conclusion or less extreme, is called the minor proposition. All this is obvious from the syllogism already given, where the conclusion is, man is accountable for his actions. For here the predicate, accountable for his actions, being connected with the middle term in the first of the two premises, every creature possessed of reason and liberty is accountable for his actions, gives what we call the major proposition. In the second of the premises, man is a creature possessed of reason and liberty, we find the less extreme, or subject of the conclusion, viz. man, connected with the same middle term, whence it is known to be the minor proposition. When a syllogism is proposed in due form, the major proposition is always placed first, the minor next, and the conclusion last.

7. These things premised, we may define reasoning to be an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known. These previous propositions, in a simple act of reasoning, are only two in number ; and it is always required that they be of themselves apparent to the understanding, so that we assent to and perceive the truth of them as soon as proposed. In the syllogism given above, the premises are supposed to be self-evident truths ; otherwise the conclusion could not be inferred by a single act of reasoning. If, for instance, in the major, 'every creature possessed of reason and liberty is accountable for his actions,' the connexion between the subject and predicate could not be perceived by a bare attention to the ideas themselves ; it is evident that this proposition would no less require a proof than the conclusion deduced from it. In this case a new middle term must be sought, to trace the connexion here supposed ; and this of course furnishes another syllogism, by which having established the proposition in question, we are then, and not before, at liberty to use it in any succeeding train of reasoning. And should it so happen, that in this second essay there were still some previous proposition whose truth did not appear at first sight, we must then have recourse to a third syllogism, to lay open that truth to the mind : because, so long as the premises remain uncertain, the conclusion built upon them must be so too. When, by conducting our thoughts in this manner, we at last arrive at some syllogism where the previous propositions are intuitive truths, the mind then rests in full security as perceiving that the se-

veral conclusions it has passed through, stand upon the immovable foundations of self-evidence.

8. We see, therefore, that, to infer a conclusion by a single act of reasoning, the premises must be intuitive propositions. Where they are not, previous syllogisms are required ; in which case reasoning becomes a complicated act, taking in a variety of successive steps. This frequently happens in tracing the more remote relation of our ideas ; where, many middle terms being called in, the conclusion cannot be made out but in consequence of a series of syllogisms following one another in train. But although, in this concatenation of propositions, those that form the premises of the last syllogism are often considerably removed from self-evidence ; yet, if we trace the reasoning backwards, we shall find them the conclusions of previous syllogisms, whose premises approach nearer and nearer to intuition in proportion as we advance, and are found at last to terminate in it. And if, after having thus performed a demonstration, we take it the contrary way ; and observe how the mind, setting out with intuitive perceptions, couples them together to form a conclusion ; how, by introducing this conclusion into another syllogism, it still advances one step farther ; and so proceeds, making every new discovery subservient to its future progress ; we shall then perceive clearly, that reasoning is no more than an orderly combination of those simple acts which we have already so fully explained.

9. Thus we see that reasoning, beginning with first principles, rises gradually from one judgment to another, and connects them in such a manner, that every stage of the progression brings with it intuitive certainty. And now we may clearly understand the definition given above of this distinguishing faculty of the human mind. Reason, we have said, is the ability of deducing unknown truths from principles or propositions that are already known. This evidently appears by the foregoing account, where we see that no proposition is admitted into a syllogism, to serve as one of the previous judgments on which the conclusion rests, unless it is itself a known and established truth, whose connexion with self-evident principles has been already traced.

SECT. II.—OF THE SEVERAL KINDS OF REASONING ; AND FIRST OF THAT BY WHICH WE DETERMINE THE GENERA AND SPECIES OF THINGS.

1. All the aims of human reason may in general be reduced to these two : 1. To rank things under those universal ideas to which they truly belong ; and, 2. To ascribe to them their several attributes and properties in consequence of that distribution.

2. One great aim of human reason is to determine the genera and species of things. We have seen, in the first part of this treatise, how the mind proceeds in framing general ideas. We have also seen, in the second part, how, by means of these general ideas, we arrive at universal propositions. Now, as in these universal propositions we affirm some property of a genus or species, it is plain that we cannot apply this property to particular objects till we have first

determined whether they are comprehended under that general idea of which the property is affirmed. Thus there are certain properties belonging to all even numbers, which cannot however be applied to any particular number, until we have first discovered it to be of the species expressed by that name. Hence reasoning begins with referring things to their several divisions and classes in the scale of our ideas; and, as these divisions are all distinguished by particular names, we hereby learn to apply the terms expressing general conceptions to such particular objects as come under our immediate observation.

3. Now, to arrive at these conclusions, by which the several objects of perception are brought under general names, two things are manifestly necessary. First, that we take a view of the idea itself denoted by that general name, and carefully attend to the distinguishing marks which serve to characterise it. Secondly, that we compare this idea with the object under consideration, observing diligently wherein they agree or differ. If the idea is found to correspond with the particular object, we then without hesitation apply to it the general name; but, if no such correspondence intervenes, the conclusion must necessarily take a contrary turn. Let us, for instance, take the number eight, and consider by what steps we are led to pronounce it an even number. First, then, we call to mind the idea signified by the expression an even number, viz. that it is a number divisible into two equal parts. We then compare this idea with the number eight, and, finding them to agree, see at once the necessity of admitting the conclusion. These several judgments, therefore, transferred into language, and reduced into the form of a syllogism, appear thus:—'Every number that may be divided into two equal parts is an even number:—The number eight may be divided into two equal parts;—Therefore the number eight is an even number.'

4. Here it may be observed, that where the general idea, to which particular objects are referred, is very familiar to the mind, and frequently in view; this reference, and the application of the general name, seem to be made without any apparatus of reasoning. When we see a horse in the fields, or a dog in the street, we readily apply the name of the species; habit, and a familiar acquaintance with the general idea, suggesting it instantaneously to the mind. We are not however to imagine on this account that the understanding departs from the usual rules of just thinking. A frequent repetition of acts begets a habit; and habits are attended with a certain promptness of execution, that prevents our observing the several steps and gradations by which any course of action is accomplished. But in other instances, where we judge not by precontracted habits, as when the general idea is very complex, or less familiar to the mind, we always proceed according to the form of reasoning established above. A goldsmith, for instance, who is in doubt as to any piece of metal, whether it be of the species called gold, first examines its properties, and then comparing them with the general idea signified by that name, if he finds a

perfect correspondence, no longer hesitates under what class of metals to rank it.

5. Nor let it be imagined that our researches here, because in appearance bounded to the imposing of general names upon particular objects, are therefore trivial and of little consequence. Some of the most considerable debates among mankind, and such too as nearly regard their lives, interest, and happiness, turn wholly upon this article. Is it not the chief employment of our several courts of judicature to determine, in particular instances, what is law, justice, and equity? Of what importance is it in many cases to decide aright, whether an action shall be termed murder or manslaughter! We see then that no less than the lives and fortunes of men often depend upon these decisions. The reason is plain. Actions, when once referred to a general idea, draw after them all that may be affirmed of that idea; insomuch that the determining the species of actions is all one with determining what proportion of praise or dispraise, commendation or blame, &c., ought to follow them. For, as it is allowed that murder deserves death, by bringing any particular action under the head of murder, we of course decide the punishment due to it.

6. But the great importance of this branch of reasoning, and the necessity of care and circumspection in referring particular objects to general ideas, is still farther evident from the practice of the mathematicians. Every one, who has read Euclid, knows that he frequently requires us to draw lines through certain points, and according to such and such directions. The figures thence resulting are often squares, parallelograms, or rectangles. Yet Euclid never supposes this from their bare appearance, but always demonstrates it upon the strictest principles of geometry. Nor is the method he takes in any thing different from that described above. Thus, for instance, having defined a square to be a figure bounded by four equal sides joined together at right angles; when such a figure arises in any construction previous to the demonstration of a proposition, yet he never calls it by that name until he has shown that its sides are equal, and all its angles right ones. Now this is apparently the same form of reasoning we have before exhibited in proving eight to be an even number.

7. Having thus explained the rules by which we are to conduct ourselves in ranking particular objects under general ideas, and shown their conformity to the practice and manner of the mathematicians, it remains only to observe, that the true way of rendering this part of knowledge both easy and certain, is, by habituating ourselves to clear and determinate ideas, and keeping them steadily annexed to their respective names. For as all our aim is to apply general words aright, if these words stand for invariable ideas that are perfectly known to the mind, and can be readily distinguished upon occasion, there will be little danger of mistake or error in our reasonings. Let us suppose that, by examining any object, and carrying our attention successively from one part to another, we have acquainted ourselves with the several particulars observable in it. If among these we find such as constitute some

general idea, framed and settled before-hand by the understanding, and distinguished by a particular name, the resemblance thus known and perceived necessarily determines the species of the object, and thereby gives it a right to the name by which that species is called. Thus four equal sides, joined together at right angles, make up the notion of a square. As this is a fixed and invariable idea, without which the general name cannot be applied, we never call any particular figure a square until it appears to have these several conditions; and, contrarily, wherever a figure is found with these conditions, it necessarily takes the name of a square. The same will be found to hold in all our other reasonings of this kind, where nothing can create any difficulty but the want of settled ideas. If, for instance, we have not determined within ourselves the precise notion denoted by the word manslaughter, it will be impossible for us to decide whether any particular action ought to bear that name: because, however nicely we examine the action itself, yet, being strangers to the general idea with which it is to be compared, we are utterly unable to judge of their agreement or disagreement. But if we take care to remove this obstacle, and distinctly trace the two ideas under consideration, all difficulties vanish, and the resolution becomes both easy and certain.

8. Thus we see of what importance it is towards the improvement and certainty of human knowledge, that we accustom ourselves to clear and determinate ideas, and a steady application of words.

SECT. III.—OF REASONING AS IT REGARDS THE POWERS AND PROPERTIES OF THINGS, AND THE RELATIONS OF OUR GENERAL IDEAS.

1. We now come to the second great end which men have in view in their reasonings: namely, the discovering and ascribing to things their several attributes or properties. And here it will be necessary to distinguish between reasoning as it regards the sciences, and as it concerns common life. In the sciences our reason is employed chiefly about universal truths, it being by them alone that the bounds of human knowledge are enlarged. Hence the division of things into various classes, called otherwise genera and species. For these universal ideas being set up as the representatives of many particular things, whatever is affirmed of them may be also affirmed of all the individuals to which they belong. Murder, for instance, is a general idea, representing a certain species of human actions. Reason tells us that the punishment due to it is death. Hence every particular action, coming under the notion of murder, has the punishment of death allotted to it. Here then we apply the general truth to some obvious instance; and this is what properly constitutes the reasoning of common life. For men, in their ordinary transactions and intercourse one with another, have, for the most part, to do only with particular objects. Our friends and relations, their characters and behaviour, the constitution of the several bodies that surround us, and the uses to which they may be applied, are what chiefly engage our attention. In all these we

reason about particular things; and the whole result of our reasoning is, the applying the general truths of the sciences in the ordinary transactions of human life. When we see a viper, we avoid it. Wherever we have occasion for the forcible action of water, to move a body that makes considerable resistance, we take care to convey it in such a manner that it shall fall upon the object with impetuosity. Now all this happens in consequence of our familiar and ready application of these two general truths. 'The bite of a viper is mortal.' 'Water, falling upon a body with impetuosity, acts very forcibly towards setting it in motion.' In like manner, if we set ourselves to consider any particular character, in order to determine the share of praise or dispraise that belongs to it, our great concern is to ascertain exactly the proportion of virtue and vice. The reason is obvious. A just determination, in all cases of this kind, depends entirely upon an application of these general maxims of morality; Virtuous actions deserve praise; vicious actions deserve blame.

2. Hence it appears that reasoning, as it regards common life, is no more than the ascribing the general properties of things to those several objects with which we are more immediately concerned, according as they are found to be of that particular division or class to which the properties belong. 'The steps then by which we proceed are manifestly these. First, we refer the object under consideration to some general idea or class of things. We then recollect the several attributes of that general idea. And, lastly, ascribe all those attributes to the present object. Thus, in considering the character of Sempronius, if we find it to be of the kind called virtuous, when we, at the same time, reflect that a virtuous character is deserving of esteem, it naturally and obviously follows that Sempronius is so too. These thoughts, put into a syllogism, in order to exhibit the form of reasoning here required, run thus:—'Every virtuous man is worthy of esteem.—Sempronius is a virtuous man;—Therefore Sempronius is worthy of esteem.'

3. By this syllogism it appears, that, before we affirm any thing of a particular object, that object must be referred to some general idea. Sempronius is pronounced worthy of esteem only in consequence of his being a virtuous man, or coming under that general notion. Hence we see the necessary connexion of the various parts of reasoning, and the dependence they have one upon another. The determining the genera and species of things is one exercise of human reason; and here we find that this exercise is the first in order, and previous to the other, which consists in ascribing to them their properties, and relations. But when we have taken this previous step, and brought particular objects under general names; as the properties we ascribe to them are no other than those of the general idea, it is plain that, in order to a successful progress in this part of knowledge, we must thoroughly acquaint ourselves with the several relations and attributes of these our general ideas. When this is done, the other part will be easy, and requires scarcely any labor

or thought, as being no more than an application of the general form of reasoning represented in the foregoing syllogism. Now, as we have already sufficiently shown how we are to proceed in determining the genera and species of things, which, as we have said, is the previous step to this second branch of human knowledge, all that is farther wanting towards a due explanation of it is, to offer some considerations as to the manner of investigating the general relations of our ideas. This is the highest exercise of the powers of the understanding, and that by means of which we arrive at the discovery of universal truths; so that our deductions in this way constitute that particular species of reasoning which regards principally the sciences.

4. But, that we may conduct our thoughts with some order and method, we shall begin with observing, that the relations of our general ideas are of two kinds: either such as immediately discover themselves, upon comparing the ideas one with another; or such as, being more remote and distant, require art and contrivance to bring them into view. The relations of the first kind furnish us with intuitive and self-evident truths. those of the second are traced by reasoning, and due application of intermediate ideas. It is of this last kind that we are to speak here, having discussed the other in the second part. As, therefore, in tracing the more distant relations of things, we must always have recourse to intervening ideas, and are more or less successful in our researches according to our acquaintance with these ideas, and ability of applying them, it is evident that, to make a good reasoner, two things are principally required. 1st, An extensive knowledge of those intermediate ideas, by means of which things may be compared one with another. 2dly, The skill and talent of applying them happily in all particular instances that come under consideration.

5. In order to our successful progress in reasoning, we must have an extensive knowledge of those intermediate ideas, by means of which things may be compared one with another. For as it is not every idea that will answer the purpose of our enquiries, but such only as are peculiarly related to the objects about which we reason, so as, by a comparison with them, to furnish evident and known truths; nothing is more apparent than that the greater variety of conceptions we can call into view, the more likely we are to find some among them that will help us to the truths here required. And, indeed, it holds in experience, that in proportion as we enlarge our views of things, and grow acquainted with a multitude of different objects, the reasoning faculty gathers strength: for, by extending our sphere of knowledge, the mind acquires a certain force and penetration, as being accustomed to examine the several appearances of its ideas, and observe what light they cast one upon another.

6. This is the reason why, in order to excel remarkably in any one branch of learning, it is necessary to have at least a general acquaintance with the whole circle of arts and sciences. All the various divisions of human knowledge are very

nearly related, and, in innumerable instances, serve to illustrate each other. And although it is not to be denied that, by a resolute application to one branch of study, a man may make considerable progress, and acquire some degree of eminence in it; yet his views will be always narrow and contracted, and he will want that masterly discernment which not only enables us to pursue our discoveries with ease, but also, in laying them open to others, to spread a certain brightness around them. But, when our reasoning regards a particular science, it is further necessary that we more nearly acquaint ourselves with whatever relates to that science. A general knowledge is a good preparation, and enables us to proceed with ease and expedition in whatever branch of learning we apply to. But then, in the minute and intricate questions of any science, we are by no means qualified to reason with advantage until we have perfectly mastered the science to which they belong.

7. We come now to the second thing required, in order to a successful progress in reasoning; namely, the skill and talent of applying intermediate ideas happily in all particular instances that come under consideration. And here rules and precepts are of little service. Use and experience are the best instructors. For, whatever logicians may boast of being able to form perfect reasoners by book and rule, we find by experience that the study of their precepts does not always add any great degree of strength to the understanding. In short, it is the habit alone of reasoning that makes a reasoner. And, therefore, the true way to acquire this talent is, by being much conversant in those sciences where the art of reasoning is allowed to reign in the greatest perfection. Hence it was that the ancients, who so well understood the manner of forming the mind, always began with mathematics as the foundation of their philosophical studies. Here the understanding is by degrees habituated to truth, contracts insensibly a certain fondness for it, and learns never to yield its assent to any proposition where the evidence is not sufficient to produce full conviction. For this reason Plato has called mathematical demonstrations the cathartics or purgatives of the soul, as being the proper means to cleanse it from error, and to promote that natural exercise of its faculties in which just thinking consists.

8. If, therefore, we would form our minds to a habit of reasoning closely and in a train, we cannot take any more certain method than exercising ourselves in mathematical demonstrations, so as to contract a kind of familiarity with them. Not that we look upon it as necessary that all men should be deep mathematicians; but that having acquired the manner of reasoning, which that study necessarily brings the mind to, they may be able to transfer it to other parts of knowledge, as they shall have occasion.

9. But though the study of mathematics be of all others the most useful to form the mind, and give it an early relish for truth, yet ought not other parts of philosophy to be neglected. For there also we meet with many opportunities of exercising the powers of the understanding; and the variety of subjects naturally leads us to ob-

serve all those different turns of thinking that are peculiarly adapted to the several ideas we examine, and the truth we search after. A mind thus trained acquires a certain mastery over its own thoughts, insomuch that it can range and model them at pleasure, and call such into view as best suit its present designs. Now in this the whole art of reasoning consists; from among a great variety of different ideas to single out those that are most proper for the business in hand, and to lay them together in such order, that from plain and easy beginnings, by gentle degrees, and a continued train of evident truths, we may be insensibly led on to such discoveries as at our first setting out appeared beyond the reach of the human understanding. For this purpose, besides the study of mathematics before recommended, we ought to apply ourselves diligently to the reading of such authors as have distinguished themselves for strength of reasoning, and a just and accurate manner of thinking. For it is observable, that a mind exercised and habituated to truth seldom rests satisfied in a bare contemplation of the arguments offered by others; but will be frequently trying its own strength, and pursuing its discoveries upon the plan it is most accustomed to. Thus we insensibly contract a habit of tracing truth from one stage to another, and of investigating those general relations and properties which we afterwards ascribe to particular things, according as we find them comprehended under the abstract ideas to which the properties belong.

SECT. IV.—OF THE FORMS OF SYLLOGISMS.

1. Having thus given a general notion of syllogisms, and their parts, we shall now enter more particularly into the subject, examine their various forms, and lay open the rules of argumentation proper to each. In the syllogisms above mentioned the middle term is the subject of the major proposition, and the predicate of the minor. This disposition, though the most natural and obvious, is not however necessary; as it often happens that the middle term is the subject in both the premises, or the predicate in both; and sometimes, directly contrary to its disposition in the preceding sections, the predicate in the major, and the subject in the minor. Hence the distinction of syllogisms into various kinds, called figures by logicians. For figure, according to their use of the word, is nothing but the order and disposition of the middle term in any syllogism. And, as this disposition is fourfold, so the figures of syllogisms thence arising are four in number. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the first figure: as, 'No work of God is bad:—The natural passions and appetites of men are the work of God:—Therefore none of them is bad.' If, on the other hand, it is the predicate of both the premises, the syllogism is said to be the second figure: as, 'Whatever is bad is not the work of God:—All the natural passions and appetites of men are the work of God:—Therefore the natural passions and appetites of men are not bad.' Again, in the third figure, the middle term is the subject of the two premises:

as, 'All Africans are black:—All Africans are men:—Therefore some men are black.' And lastly, by making it the predicate of the major and subject of the minor, we obtain syllogisms in the fourth figure: as, 'The only being who ought to be worshipped is the Creator and Governor of the world:—The Creator and Governor of the world is God:—Therefore God is the only being who ought to be worshipped.'

2. But, besides this fourfold distinction of syllogisms, there is a further subdivision of them in every figure, arising from the quantity and quality, as they are called, of the propositions. By quantity we mean the consideration of propositions, as universal or particular; by quality, as affirmative or negative.

Now as, in all the several dispositions of the middle term, the propositions of which a syllogism consists may be either universal or particular, affirmative or negative, the due determination of these, and so putting them together as the laws of argumentation require, constitute what logicians call the moods of syllogisms. Of these moods there is a determinate number to every figure, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion.

The first figure has only four legitimate moods. The major proposition in this figure must be universal, and the minor affirmative; and it has this property, that it yields conclusions of all kinds, affirmative and negative, universal and particular.

The second figure has also four legitimate moods. Its major proposition must be universal, and one of the premises must be negative. It yields conclusions both universal and particular, but all negative.

The third figure has six legitimate moods. Its minor must always be affirmative; and it yields conclusions both affirmative and negative, but all particular. These are all the figures which were admitted by the inventor of syllogisms; and of which, so far as we know, the number of legitimate moods has been ascertained, and severally demonstrated. In every figure it will be found upon trial that there are sixty-four different moods of syllogism; and he who thinks it worth while to construct so many in the fourth figure, always remembering that the middle term in each must be the predicate of the major and the subject of the minor proposition, will easily discern what number of these moods are legitimate, and give true conclusions.

Besides the rules that are proper to each figure, Aristotle has given some that are common to all, by which the legitimacy of syllogisms may be tried. These may be reduced to five:

1. There must be only three terms in a syllogism: as each term occurs in two of the propositions, it must be precisely the same in both; if it be not, the syllogism is said to have four terms, which makes a vicious syllogism.
2. The middle term must be taken universally in one of the premises.
3. Both premises must not be particular propositions, nor both negative.
4. The conclusion must be particular, if either

of the premises be particular; and negative, if either of the premises be negative. 5. No term can be taken universally in the conclusion, if it be not taken universally in the premises.

For understanding the second and fifth of these rules, it is necessary to observe, that a term is said to be taken universally, not only when it is the subject of a universal proposition, but also when it is the predicate of a negative proposition. On the other hand, a term is said to be taken particularly, when it is either the subject of a particular, or the predicate of an affirmative proposition.

3. The division of syllogisms, according to mood and figure, respects those especially which are known by the name of plain simple syllogisms; that is, which are bound to three propositions, all simple, and where the extremes and middle term are connected, according to the above rules. But as the mind is not tied down to any one precise form of reasoning, but sometimes makes use of more, sometimes of fewer premises, and often takes in compound and conditional propositions, it may not be amiss to take notice of the different forms derived from this source, and explain the rules by which the mind conducts itself in the use of them.

4. When in any syllogism the major is a conditional proposition, the syllogism itself is termed conditional. Thus: 'If there is a God, he ought to be worshipped:—But there is a God:—Therefore he ought to be worshipped.' In this example the major, or first proposition, is conditional, and therefore the syllogism itself is also of the same kind. And here we must observe, that all conditional propositions consist of two distinct parts: one expressing the condition upon which the predicate agrees or disagrees with the subject, as in this now before us, if there is a God; the other joining or disjoining the said predicate and subject, as here, he ought to be worshipped. The first of these parts, or that which implies the condition, is called the antecedent; the second, where we join or disjoin the predicate and subject, has the name of the consequent.

5. In all propositions of this kind, supposing them to be exact in point of form, the relation between the antecedent and consequent must ever be true and real; that is, the antecedent must always contain some certain and genuine condition, which necessarily implies the consequent; for otherwise the position itself will be false, and therefore ought not to be admitted into our reasonings. Hence it follows, that when any conditional proposition is assumed, if we admit the antecedent of that proposition, we must at the same time necessarily admit the consequent; but, if we reject the consequent, we are in like manner bound to reject the antecedent. For as the antecedent always expresses some condition which necessarily implies the truth of the consequent; by admitting the antecedent, we allow of that condition, and therefore ought also to admit the consequent. In like manner, if it appears that the consequent ought to be rejected, the antecedent evidently must be so too; because, as has just been demonstrated, the admitting of

the antecedent would necessarily imply the admission also of the consequent.

6. There are two ways of arguing in hypothetical syllogisms, which lead to a certain and unavoidable conclusion. For as the major is always a conditional proposition, consisting of an antecedent and a consequent; if the minor admits the antecedent, it is plain that the conclusion must admit the consequent. This is called arguing from the admission of the antecedent to the admission of the consequent, and constitutes that mood or species of hypothetical syllogisms which is distinguished in the schools by the name of the *modus ponens*, as by it the whole conditional proposition, both antecedent and consequent, is established. Thus: If God is infinitely wise, and acts with perfect freedom, he does nothing but what is best:—But God is infinitely wise, and acts with perfect freedom:—Therefore he does nothing but what is best.' Here we see the antecedent or first part of the conditional proposition is established in the minor, and the consequent or second part in the conclusion; whence the syllogism itself is an example of the *modus ponens*. But if now we on the contrary suppose that the minor rejects the consequent, then it is apparent that the conclusion must also reject the antecedent. In this case we are said to argue from the removal of the consequent to the removal of the antecedent, and the particular mood or species of syllogism thence arising is called by logicians the *modus tollens*; because in it both antecedent and consequent are rejected or taken away, as appears by the following example. 'If God were not a being of infinite goodness, neither would he consult the happiness of his creatures:—But God does consult the happiness of his creatures:—Therefore he is a being of infinite goodness.'

7. These two species take in the whole class of conditional syllogisms, and include all the possible ways of arguing that lead to a legitimate conclusion; because we cannot here proceed by a contrary process of reasoning, that is, from the removal of the antecedent to the removal of the consequent, or from the establishing of the consequent to the establishing of the antecedent. For although the antecedent always expresses some real condition, which, once admitted, necessarily implies the consequent, yet it does not follow that there is therefore no other condition; and if so, then, after removing the antecedent, the consequent may still hold, because of some other determination that infers it. When we say, If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat; the proposition is certainly true; and, admitting the antecedent, we must also admit the consequent. But, as there are other ways by which a stone may gather heat, it will not follow from the ceasing of the before-mentioned condition, that therefore the consequent cannot take place. We cannot argue: but the stone has not been exposed to the rays of the sun; therefore neither has it any degree of heat: for there are many other ways by which heat might be communicated to it. And, if we cannot argue from the removal of the antecedent to the removal of

the consequent, neither can we from the admission of the consequent to the admission of the antecedent : because, as the consequent may flow from a great variety of different suppositions, the allowing of it does not determine the precise supposition, but only that some one of them must take place. Thus, in the foregoing propositions,

If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat; admitting the consequent, viz. that it has contracted a certain degree of heat, we are not therefore bound to admit the antecedent, that it has been some time exposed to the rays of the sun; because there are many other causes whence that heat may have proceeded. These two ways of arguing, therefore, hold not in conditional syllogisms.

8. As, from the major being a conditional proposition, we obtain the species of conditional syllogisms; so, where it is a disjunctive proposition, the syllogism to which it belongs is also called disjunctive, as in the following example:— 'The world is either self-existent, or the work of some finite, or of some infinite being:—But it is not self-existent, nor the work of a finite being:—Therefore it is the work of an infinite Being.'

Now, a disjunctive proposition is that, in which, of several predicates, we affirm one necessarily to belong to the subject, to the exclusion of all the rest, but leave that particular one undetermined. Hence it follows that, as soon as we determine the particular predicate, all the rest are of course to be rejected; or if we reject all the predicates but one, that one necessarily takes place. When, therefore, in a disjunctive syllogism, the several predicates are enumerated in the major; if the minor establishes any one of these predicates, the conclusion ought to remove all the rest; or if in the minor all the predicates but one are removed, the conclusion must necessarily establish that one. Thus, in the disjunctive syllogism given above, the major affirms one of the three predicates to belong to the earth, viz. self-existence, or that it is the work of a finite, or that it is the work of an infinite Being. Two of these predicates are removed in the minor, viz. self-existence, and the work of a finite being. Hence the conclusion necessarily ascribes to it the third predicate, and affirms that it is the work of an infinite Being. If we give the syllogism another turn, so that the minor may establish one of the predicates, by affirming the earth to be the production of an infinite Being: then the conclusion must remove the other two, asserting it to be neither self-existent, nor the work of a finite being. These are the forms of reasoning in these species of syllogisms, the justness of which appears at first sight: and that there can be no other is evident from the very nature of a disjunctive proposition.

9. In the several kinds of syllogisms hitherto mentioned, we may observe, that the parts are complete; that is, the three propositions of which they consist are represented in form. But it often happens, that some one of the premises is not only an evident truth, but also familiar and in the minds of all men; in which case it is usually omitted, whereby we have an imperfect syllogism that seems to be made up of only two propositions.

Should, we, for instance, argue in this manner:— 'Every man is mortal:—therefore every king is mortal:—the syllogism appears to be imperfect, as consisting but of two propositions. Yet it is really complete; only the minor (every king is a man) is omitted; and left to the reader to supply, as being a proposition so familiar and evident that it cannot escape him.

10. These seemingly imperfect syllogisms are called *enthymemes*; and occur very frequently in reasoning, especially where it makes a part of common conversation. Nay, there is a particular elegance in them, because, not displaying the argument in all its parts, they leave somewhat to the exercise and invention of the mind. We are thus put upon exerting ourselves, and seem to share in the discovery of what is proposed to us. Now this is the great secret of fine writing, ~~to~~ to frame and put together our thoughts as to give full play to the reader's imagination, and draw him insensibly into our views and course of reasoning. This gives a pleasure not unlike to that which the author himself feels in composing. It besides shortens discourse, and adds a certain force and liveliness to our arguments, when the words in which they are conveyed favor the natural quickness of the mind in its operations, and a single expression is left to exhibit a whole train of thoughts.

11. But there is another species of reasoning with two propositions, which seems to be complete in itself, and where we admit the conclusion without supposing any tacit or suppressed judgment in the mind, from which it follows syllogistically. This happens between propositions, where the connexion is such, that the admission of the one necessarily, and at the first sight, implies the admission also of the other. For if the proposition on which the other depends is self-evident, we content ourselves with barely affirming it, and infer that other by a direct conclusion. Thus, by admitting a universal proposition, we are forced also to admit of all the particular propositions comprehended under it, this being the very condition that constitutes a proposition universal. If then that universal proposition be self-evident, the particular ones follow of course, without any farther train of reasoning. Whoever allows, for instance, 'that things equal to one and the same thing are equal to one another,' must at the same time allow, 'that two triangles, each equal to a square whose side is three inches, are also equal between themselves.' This argument, therefore,— 'Things equal to one and the same thing, are equal to one another:—Therefore these two triangles, each equal to the square of a line of three inches, are equal between themselves:—' is complete in its kind, and contains all that is necessary towards a just and legitimate conclusion. For the first or universal proposition is self-evident, and therefore requires no farther proof. And as the truth of the particular is inseparably connected with that of the universal, it follows from it by an obvious and unavoidable consequence.

12. Now, in all cases of this kind, where propositions are deduced one from another, on account of a known and evident connexion, we are said to reason by immediate consequence. Such

a coherence of propositions, manifest at first sight, and forcing itself upon the mind, frequently occurs in reasoning. Logicians have explained at some length the several suppositions upon which it takes place, and allow of all immediate consequences that follow in conformity to them. It is however observable, that these arguments, though seemingly complete, because the conclusion follows necessarily from the single proposition that goes before, may yet be considered as real enthymemes, whose major, which is a conditional proposition, is wanting. The syllogism just mentioned, when represented according to this view, will run as follows:—‘If things equal to one and the same thing, are equal to one another; these two triangles, each equal to a square whose side is three inches, are also equal between themselves. But things equal to one and the same thing are equal to one another:—therefore also these triangles, &c., are equal between themselves.’ This observation will be found to hold in all immediate consequences whatsoever, so that they are in fact no more than enthymemes of hypothetical syllogisms. But then it is particular to them, that the ground on which the conclusion rests, namely its coherence with the minor, is of itself apparent, and seems immediately to flow from the rules and reasons of logic.

13. The next species of reasoning we shall notice here is what is commonly known by the name of *sorites*. This is a way of arguing, in which a great number of propositions are so linked together, that the predicate of one becomes continually the subject of the next following, until at last a conclusion is formed, by bringing together the subject of the first proposition, and the predicate of the last. Of this kind is the following argument:—‘God is omnipotent:—an omnipotent being can do every thing possible: he that can do every thing possible, can do whatever involves not a contradiction:—therefore God can do whatever involves not a contradiction.’ This particular combination of propositions may be continued to any length we please, without in the least weakening the ground upon which the conclusion rests. The reason is, because the *sorites* itself may be resolved into as many simple syllogisms as there are middle terms in it; where this is found universally to hold, that when such a resolution is made, and the syllogisms are placed in train, the conclusion of the last in the series is also the conclusion of the *sorites*. This kind of argument, therefore, as it serves to unite several syllogisms into one, must stand upon the same foundation with the syllogisms of which it consists, and is indeed, properly speaking, no other than a compendious way of reasoning syllogistically.

14. What is here said of plain simple propositions, may be as well applied to those that are conditional; that is, any number of them may be so joined together in a series, that the consequent of one shall become continually the antecedent of the next following; in which case, by establishing the antecedent of the first proposition, we establish the consequent of the last, or, by removing the last consequent, remove also the first antecedent. This way of reasoning

is exemplified in the following argument:—‘If we love any person, all emotions of hatred towards him cease:—If all emotions of hatred towards a person cease, we cannot rejoice in his misfortunes:—If we rejoice not in his misfortunes, we certainly wish him no injury:—Therefore, if we love a person, we wish him no injury.’ It is evident that this *sorites*, as well as the last, may be resolved into a series of distinct syllogisms, with this only difference, that here the syllogisms are all conditional.

15. The last species of syllogism we shall take notice of in this section is that commonly distinguished by the name of a *dilemma*. A dilemma is an argument by which we endeavour to prove the absurdity or falsehood of some assertion. In order to this, we assume a conditional proposition, the antecedent of which is the assertion to be disproved, and the consequent a disjunctive proposition, enumerating all the possible suppositions upon which that assertion can take place. If then it appears, that all these several suppositions are to be rejected, it is plain, that the antecedent or assertion itself must be so too. When, therefore, such a proposition as that before mentioned is made the major of any syllogism; if the minor rejects all the suppositions contained in the consequent, it necessarily follows, that the conclusion ought to reject the antecedent, which is the very assertion to be disproved. This particular way of arguing is that which logicians call a dilemma; and, from the account here given of it, it appears that we may in the general define it to be a hypothetical syllogism, where the consequent of the major is a disjunctive proposition, which is wholly taken away or removed in the minor. Of this kind is the following:—‘If God did not create the world perfect in its kind, it must either proceed from want of inclination, or from want of power:—But it could not proceed either from want of inclination or want of power:—Therefore, he created the world perfect in its kind.’ Or, which is the same thing: ‘It is absurd to say that he did not create the world perfect in its kind.’

16. The nature, then, of a dilemma is universally this. The major is a conditional proposition, whose consequent contains all the several suppositions upon which the antecedent can take place. As, therefore, these suppositions are wholly removed in the minor, it is evident that the antecedent must be so too; inasmuch that we here always argue from the removal of the consequent to the removal of the antecedent. That is, a dilemma is an argument in the *modus tollens* of hypothetical syllogisms, as logicians speak. Hence it is plain that, if the antecedent of the major is an affirmative proposition, the conclusion of the dilemma will be negative; but, if it is a negative proposition, the conclusion will be affirmative.

SECT. V.—OF INDUCTION.

1. All reasoning proceeds ultimately from first truths, either self-evident or taken for granted; and the first truths of syllogistic reasonings are general propositions. But except in the mathematics, and such other sciences as, being con-

versant about mere ideas, have no immediate relation to things without the mind, we cannot assume as truths propositions which are general. The mathematician, indeed, may be considered as taking his ideas from the beginning in their general form. Every proposition composed of such ideas is therefore general; and those which are theoretic are reducible to two parts or terms, a predicate and a subject, with a copula generally affirmative. If the agreement or the relation between the two terms be not immediate and self-evident, he has recourse to an axiom, which is a proposition still more general, and which supplies him with a third or middle term. This he compares first with the predicate, and then with the subject, or vice versâ. These two comparisons, when drawn out in form, make two propositions, which are called the premises; and, if they be immediate and self-evident, the conclusion, consisting of the terms of the question proposed, is said to be demonstrated. This method of reasoning is conducted exactly in the syllogistic form explained in the preceding section.

2. But, in sciences which treat of things external to the mind, we cannot assume as first principles the most general propositions, and from them infer others less and less general till we descend to particulars. The reason is obvious. Every thing in the universe, whether of mind or body, presents itself to our observation in its individual state; so that perception and judgment, employed in the investigation of truth, whether physical, metaphysical, moral, or historical, have in the first place to encounter with particulars. 'With these reason begins or should begin, its operations. It observes, examines, compares, and judges of them by some of those native evidences and original lights which, as they are the first and indispensable inlets of knowledge to the mind, have been called the primary principles of truth.'

3. 'By such acts of observation and judgment,' says that accurate logician, Mr. Tatham, 'diligently practised, and frequently repeated, on many individuals of the same class or of a similar nature, noting their agreements, marking their differences, however minute, and rejecting all instances which, however similar in appearance, are not in effect the same, reason, with much labor and attention, extracts some general laws respecting the properties and relations of real things.' This is no hasty, premature, notional abstraction of the mind, by which ideas are formed that have no archetypes in nature: it is a rational experimental process, instituted and executed upon the constitution of beings, which in part compose the universe. By this process reason advances from particulars to generals, from less general to more general, till by a series of slow progression, and by regular degrees, it arrives at the most general notions. And by affirming or denying a genus of a species, or an accident of a substance or class of substances, through all the stages of the gradation, we form conclusions, which, if logically drawn, are axioms, or general propositions ranged one above another, till they terminate in those that are universal.

4. 'Thus, for instance, the evidence of the ex-

ternal senses is obviously the primary principle from which all physical knowledge is derived. But, whereas nature begins with causes, which, after a variety of changes, produce effects, the senses open upon the effects, and from them, through the slow and painful road of experiment and observation, ascend to causes. By experiment and observations skilfully chosen, carefully conducted, and judiciously applied, the philosopher advances from one stage of enquiry to another, in the rational investigation of the general causes of physical truth. From different experiments and observations made on the same individual subject, and from the same experiments and observations made on different subjects of the same kind, by comparing and judging, he discovers some qualities, causes, or phenomena, which, after carefully distinguishing and rejecting all contradictory instances that occur, he finds common to many. Thus, from many collateral comparisons and judgments formed upon particulars, he ascends to generals; and, by a repetition of the same industrious process and laborious investigation, he advances from general to more general, till at last he is enabled to form a few of the most general, with their attributes and operations, into axioms or secondary principles, which are the well-founded laws enacted and enforced by the God of nature. This is that just and philosophic method of reasoning which sound logic prescribes, in this as well as in other parts of learning; by which, through the slow but certain road of experiment and observation, the mind ascends from appearances to qualities, from effects to causes, and, from experiments upon many particular subjects, forms general propositions concerning the powers and properties of physical body.

5. 'Axioms so investigated and established are applicable to all parts of learning, and are the indispensable, and, indeed, the wonderful dependencies, by which, in every branch of knowledge, reason pushes on its enquiries to the particular pursuit of truth: and the method of reasoning by which they are formed is that of true and legitimate induction; which is, therefore, by lord Bacon, the best and soundest of logicians, called 'the key of interpretation.'

6. 'Instead of taking his axioms promiscuously or arbitrarily out of the great families of the categories, and erecting them by his own sophistical invention into the principles upon which his disputation was to be employed, had the analytical genius of Aristotle presented us with the laws of the true inductive logic, by which axioms are philosophically formed, and had he, with his usual sagacity, given us an example of it in a single branch of science; he would have brought to the temple of truth an offering more valuable than he has done by the aggregate of all his logical and philosophical productions.

7. 'In all sciences, except the mathematics, it is only after the inductive process has been industriously pursued and successfully performed, that definition may be logically and usefully introduced, by beginning with the genus, passing through all the graduate and subordinate stages, and marking the specific difference as it

descends, till it arrive at the individual, which is the subject of the question. And, by adding an affirmation or negation of the attribute of the genus on the species or individual, or of a general accident on the particular substance so defined, making the definition a proposition, the truth of the question will be logically solved without any farther process. So that instead of being the first, as employed by the logic in common use, definition may be the last act of reason in the search of truth in general.

8. 'These axioms, or general propositions, thus inductively established, become another species of principles, which may be properly called secondary, and which lay the foundation of the syllogistic method of reasoning. When these are formed, but not before, we may safely admit the maxim with which logicians set out in the exercise of their art, as the great hinge on which their reasoning and disputation turn: 'From truths that are already known, to derive others which are not known.' Or, to state it more comprehensively, so as to apply to probable as well as to scientific reasoning—'From truths which are better known, to derive others which are less known.' Philosophically speaking, syllogistic reasoning is, under general propositions to reduce others which are less general, or which are particular; for the inferior ones are known to be true, only as we trace their connexion with the superior. Logically speaking, it is, To predicate a genus of a species or individual comprehended under it, or an accident of the substance in which it is inherent.

9. 'Thus *induction* and *syllogism* are the two methods of direct reasoning corresponding to the two kinds of principles, primary and secondary, on which they are founded, and by which they are respectively conducted. In both methods, indeed, reason proceeds by judging and comparing, but the process is different throughout; and, though it may have the sanction of Aristotle, an inductive syllogism is a solecism.

10. 'Till general truths are ascertained by induction, the third or middle terms by which syllogisms are made, are no where safely to be found. So that another position of the Stagyræite, that 'syllogism is naturally prior in order to induction,' is equally unfounded; for induction does not only naturally but necessarily precede syllogism; and, except in mathematics, is in every respect indispensable to its existence; since, till generals are established, there can be neither definition, proposition, nor axiom, and of course no syllogism. And, as induction is the first, so is it the more essential and fundamental instrument of reasoning: for, as syllogism cannot produce its own principles, it must have them from induction: and if the general propositions, or secondary principles, be imperfectly or infirmly established, and much more, if they be taken at hazard, upon authority, or by arbitrary assumption, like those of Aristotle, all the syllogising in the world is a vain and useless logomachy, only instrumental to the multiplication of false learning, and to the invention and confirmation of error. The truth of syllogisms depends ultimately on the truth of axioms, and the truth of axioms on the soundness of inductions.'

Tatham's Chart and Scale of Truth. But though induction is prior in order, as well as superior in utility, to syllogism, we have thought it expedient to treat of it last; both because syllogism is an easier exercise of the reasoning faculty than induction, and because it is the method of mathematics, the first science of reason in which the student is commonly initiated.

SECT. VI.—OF DEMONSTRATION.

1. Having despatched what seemed necessary with regard to induction and syllogism; we now proceed to consider the laws of demonstration. And here it must be confessed that, in strict demonstration, which removes from the mind all possibility of doubt or error, the inductive method of reasoning can have no place. When the experiments and observations from which the general conclusion is drawn are numerous and extensive, the result of this mode of reasoning is moral certainty; and, could the inductions be made complete, it would be absolute certainty, equally convincing with mathematical demonstration. But however numerous and extensive the observations and experiments may be, upon which an inductive conclusion is established, they must of necessity come short of the number and extent of nature; which in some cases, by its immensity, defeats all possibility of their co-extension; and in others, by its distance, lie out of the reach of their immediate application. Though truth does not appear in all other departments of learning with that bold and resistless conviction with which it presides in mathematical science, it shines through them all, if not interrupted by prejudice or perverted by error, with a clear and useful, though inferior strength. And as it is not necessary, for the general safety or convenience of a traveller, that he should always enjoy the heat and splendor of a mid-day sun, whilst he can with much more ease pursue his journey under the weaker influence of a morning or an evening ray; so it is not requisite, for the various concerns and purposes of life, that men should be led by truth of the most redundant brightness. Such truth is to be had only in those sciences which are conversant about ideas and their various relations; where, every thing being certainly what it appears to be, definitions and axioms arise from mere intuition. Here syllogism takes up the process from the beginning; and by a sublime intellectual motion advances from the simplest axioms to the most complicated speculations, and exhibits truth springing out of its first and purest elements, and spreading on all sides into a system of science. As each step in the progress is syllogistic, we shall endeavour to explain the use and application of syllogisms in this species of reasoning.

We have seen that, in all the different appearances they put on, we still arrive at a just and legitimate conclusion: now it often happens, that the conclusion of one syllogism becomes a previous proposition in another; by which means great numbers of them are sometimes linked together in a series, and truths are made to follow one another in train. And as in such a concatenation of syllogisms all the various ways of

reasoning that are truly conclusive may be with safety introduced; hence it is plain, that in deducing any truth from its first principles, especially where it lies at a considerable distance from them, we are at liberty to combine all the several kinds of syllogisms above explained, according as they are found best to suit the end and purpose of our enquiries. When a proposition is thus, by means of syllogisms, collected from others more evident and known, it is said to be proved; so that we may, in general, define the proof of a proposition to be a syllogism, or a series of syllogisms, collecting that proposition from known and evident truths. But, more particularly, if the syllogisms of which the proofs consist admit of no premises but definitions, self-evident truths, and propositions already established, then is the argument so constituted called a demonstration: whereby it appears that demonstrations are ultimately founded on definitions and self-evident propositions.

2. All syllogisms, whether compound, multi-form, or defective, are reducible to plain simple syllogisms in some one of the four figures. But this is not all. Syllogisms of the first figure, in particular, admit of all possible conclusions: that is, any proposition, whether a universal affirmative or universal negative, a particular affirmative or particular negative, which fourfold division embraces all their varieties; any one of these may be inferred by virtue of some syllogism in the first figure. By these means it happens, that the syllogisms of all the other figures are reducible also to syllogisms of the first figure, and may be considered as standing on the same foundation with them. To demonstrate and explain the manner of this reduction would too much swell this treatise. It is enough to notice that the thing is universally known and allowed among logicians, to whose writings we refer such as desire farther satisfaction in this matter. This then being laid down, it is plain that any demonstration whatever may be considered as composed of a series of syllogisms, all in the first figure. For, since all the syllogisms that enter the demonstration are reducible to syllogisms of some one of the four figures; and since the syllogisms of all the other figures are farther reducible to syllogisms of the first figure, it is evident, that the whole demonstration may be resolved into a series of these last syllogisms. Let us now, if possible, discover the ground on which the conclusion rests in syllogisms of the first figure; because, by so doing, we shall arrive at a universal principle of certainty, whence the evidence of all demonstrations in all their parts may be ultimately derived.

3. The rules, then, of the first figure are briefly these: the middle term is the subject of the major proposition, and the predicate of the minor. The major is always a universal proposition, and the minor always affirmative. Let us now see what effect these rules will have in reasoning. The major is a universal proposition of which the middle term is the subject, and the predicate of the conclusion the predicate. Hence it appears, that in the major the predicate of the conclusion is always affirmed or denied universally of the middle term. Again,

the minor is an affirmative proposition, whereof the subject of the conclusion is the subject, and the middle term the predicate. Here then the middle term is affirmed of the subject of the conclusion; that is, the subject of the conclusion is affirmed to be comprehended under, or to make a part of, the middle term. Thus then we see what is done in the premises of a syllogism of the first figure. The predicate of the conclusion is universally affirmed or denied of some idea. The subject of the conclusion is affirmed to be or to make a part of that idea. Hence it naturally and unavoidably follows, that the predicate of the conclusion ought to be affirmed or denied of the subject. To illustrate this by an example, we shall resume one of the syllogisms of the first section: 'every creature possessed of reason and liberty is accountable for his actions:—Man is a creature possessed of reason and liberty:—Therefore man is accountable for his actions.' Here, in the first proposition, the predicate of the conclusion, accountability, is affirmed of all creatures that have reason and liberty. Again, in the second proposition, man, the subject of the conclusion, is affirmed to be or to make a part of this class of creatures. Hence the conclusion necessarily and unavoidably follows, viz. that man is accountable for his actions; because, if reason and liberty be that which constitutes a creature accountable, and man has reason and liberty, it is plain he has that which constitutes him accountable. In like manner, where the major is a negative proposition, or denies the predicate of the conclusion universally of the middle term, as the minor always asserts the subject of the conclusion to be or make part of that middle term, it is no less evident that the predicate of the conclusion ought in this case to be denied of the subject. So that the ground of reasoning, in all syllogisms of the first figure, is manifestly this, 'whatever may be affirmed universally, of any idea, may be affirmed of every one or any number of particulars comprehended under that idea.' And again, 'whatever may be denied universally, of any idea, may be in like manner denied of every one or any number of its individuals. These two propositions are called by logicians the dictum de omni, and dictum de nullo; and are indeed the great principles of syllogistic reasoning, as all conclusions whatever either rest immediately upon them, or upon propositions deduced from them. But what adds greatly to their value is, that they are really self-evident truths, and such as we cannot gainsay without running into an express contradiction. To affirm, for instance, that no man is perfect, and yet argue that some men are perfect; or to say that all men are mortal, and yet that some men are not mortal, is to assert a thing to be and not to be at the same time.

4. And now we may affirm that, in all syllogisms of the first figure, if the premises are true, the conclusion must also be true. If it be true that the predicate of the conclusion, whether affirmative or negative, agrees universally to some idea; and if it be also true that the subject of the conclusion is a part of, or comprehended under that idea; then it necessarily follows, that

the predicate of the conclusion agrees also to the subject. For to assert the contrary, would be to run counter to some one of the two principles before established; that is, it would be to maintain an evident contradiction. And thus we are come at last to the point we have been all along endeavouring to establish; namely, that every proposition which can be demonstrated is necessarily true. For as every demonstration may be resolved into a series of syllogisms, all in the first figure; and as in any one of these syllogisms, if the premises are true, the conclusion must be so too; it evidently follows that, if all the several premises are true, all the several conclusions are so, and consequently the conclusion also of the last syllogism, which is always the proposition to be demonstrated. Now, that all the premises of a demonstration are true, will easily appear from the very nature and definition of that form of reasoning. A demonstration is a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established. Definitions are identical propositions, wherein we connect the description of an idea with the name by which we choose to have that idea called, and therefore as to their truth there can be no dispute. Self-evident propositions appear true of themselves, and leave no doubt or uncertainty in the mind. Propositions before established are no other than conclusions gained, by one or more steps, from definitions and self-evident principles, that is, from true premises, and therefore must needs be true. Whence, all the previous propositions of a demonstration being manifestly true, the last conclusion, or proposition to be demonstrated, must be so too. So that demonstration not only leads to certain truth, but we have here also a clear view of the ground and foundation of that certainty. For as, in demonstrating, we may be said to do nothing more than combine a series of syllogisms together, all resting on the same bottom; it is plain that one uniform ground of certainty runs through the whole, and that the conclusions are every where built upon some one of the two principles before established as the foundation of all reasoning. These two principles are easily reduced into one, and may be expressed thus: whatever predicate, whether affirmative or negative, agrees universally to any idea; the same must agree to every one or any number of individuals comprehended under that idea. And thus we have, according to our first design, reduced the certainty of demonstration to one simple and universal principle, which carries its own evidence with it, and which is indeed the ultimate foundation of all syllogistic reasoning.

5. Demonstration therefore serving as an infallible guide to truth, and standing on so sure and unalterable a basis, we may now venture to assert, that the rules of logic furnish a sufficient criterion for distinguishing between truth and falsehood. For, since every proposition that can be demonstrated is necessarily true, he is able to distinguish truth from falsehood, who can with certainty judge when a proposition is truly demonstrated. Now a demonstration is nothing more than a concatenation of syllogisms, all whose

premises are definitions, self-evident truths, or propositions previously established. To judge therefore of the validity of a demonstration, we must distinguish whether the definitions that enter it are genuine and truly descriptive of the ideas they are meant to exhibit; whether the propositions assumed without proofs as intuitive truths have really that self-evidence to which they lay claim: whether the syllogisms are drawn up in due form, and agreeable to the laws of argumentation: in fine, whether they are combined together in a just and orderly manner, so that no demonstrable propositions serve any where as premises unless they are conclusions of previous syllogisms. Now it is the business of logic, in explaining the several operations of the mind, fully to instruct in all these points. It teaches the nature and end of definitions, and lays down the rules by which they ought to be framed. It unfolds the several species of propositions, and distinguishes the self-evident from the demonstrable. It delineates also the different forms of syllogisms, and explains the laws of argumentation proper to each. In fine, it describes the manner of combining syllogisms, so as that they may form a train of reasoning, and lead to the successive discovery of truth. The precepts of logic, therefore, as they enable us to judge with certainty when a proposition is duly demonstrated, furnish a sure criterion for the distinguishing between truth and falsehood.

6. Perhaps it may be objected, that demonstration is a thing very rare and uncommon, as being the prerogative of but a few sciences, and therefore the criterion here given can be of no great use. But wherever, by the bare contemplation of our ideas, truth is discoverable, there also demonstration may be attained. Now that is an abundantly sufficient criterion which enables us to judge with certainty in all cases where the knowledge of truth comes within our reach; for, with discoveries that lie beyond the limits of the human mind, we have, properly, no business. When a proposition is demonstrated, we are certain of its truth. When, on the contrary, our ideas are such as have no visible connexion or repugnance, and therefore furnish not the proper means of tracing their agreement or disagreement, there we are sure that scientific knowledge is not attainable. But where there is some foundation of reasoning, which yet amounts not to the full evidence of demonstration, there the precepts of logic, by teaching us to determine aright of the degree of proof, and of what is still wanting to render it full and complete, enable us to make a due estimate of the measures of probability, and to proportion our assent to the grounds on which the proposition stands. And this is all we can possibly arrive at, or even so much as hope for, in the exercise of faculties so imperfect and limited as ours.

7. Before we conclude this section, it is proper to take notice of the distinction of demonstration into *direct* and *indirect*. A direct demonstration is, when, beginning with definitions, self-evident propositions, or known and allowed truths, we form a train of syllogisms, and combine them in an orderly manner, continuing the series through a variety of successive steps, until

at last we arrive at a syllogism whose conclusion is the proposition to be demonstrated. Proofs of this kind leave no doubt or uncertainty behind them; because, all the several premises being true, the conclusion must be so too, and of course the very last conclusion or proposition to be proved. The other species of demonstration is the indirect, or, as it is sometimes called, the apagogical. The manner of proceeding here is, by assuming a proposition which directly contradicts that which we mean to demonstrate; and thence, by a continued train of reasoning, in the way of a direct demonstration, deducing some absurdity or manifest untruth. For hereupon we conclude that the proposition assumed was false; and thence again, by an immediate consequence, that the proposition to be demonstrated is true. Thus Euclid, in his third book, being to demonstrate that circles which touch one another inwardly have not the same centre, assumes the direct contrary to this, viz. that they have the same centre; and thence, by an evident train of reasoning, proves that a part is equal to the whole. The supposition therefore leading to this absurdity he concludes to be false, and thence immediately infers, that they have not the same centre.

8. Now, because this manner of demonstration is accounted by some not altogether so clear and satisfactory, we shall therefore endeavour to show that it leads to truth and certainty equally with the other. Two propositions are said to be contradictory, when that which is asserted to be in the one is asserted not to be in the other. Thus the propositions, Circles that touch one another inwardly have the same centre, and Circles that touch one another inwardly have not the same centre, are contradictories, because the second asserts the direct contrary of what is asserted in the first. Now, in all contradictory propositions, this holds universally, that one of them is necessarily true, and the other necessarily false. For, if it be true that circles which touch one another inwardly have not the same centre, it is unavoidably false that they have the same centre. On the other hand, if it be false that they have the same centre, it is necessarily true that they have not the same centre. Since therefore it is impossible for them to be both true or both false at the same time; it unavoidably follows that one is necessarily true, and the other necessarily false. This then being allowed, which is indeed self-evident, if any two contradictory propositions are assumed, and one of them can, by a clear train of reasoning, be demonstrated to be false, it necessarily follows that the other is true. For, as the one is necessarily true and the other necessarily false, when we come to discover which is the false proposition, we thereby also know the other to be true.

9. Now this is precisely the manner of an indirect demonstration, as is evident from the account given of it above. For there we assume a proposition which directly contradicts that which we mean to demonstrate; and having, by a continued series of proofs, shown it to be false, thence infer that its contradictory, or the proposition to be demonstrated, is true. As, therefore, this last conclusion is certain and unavoidable;

let us next enquire after what manner we come to be satisfied of the falsehood of the assumed proposition, that so no possible doubt may remain as to the force and validity of demonstrations of this kind. The manner then is plainly this: Beginning with the assumed proposition, we, by the help of definitions, self-evident truths, or propositions already established, continue a series of reasoning, in the way of a direct demonstration, until at length we arrive at some absurdity or known falsehood. Thus Euclid, in the example before-mentioned, from the supposition that circles touching one another inwardly have the same centre, deduces, that a part is equal to the whole. Since, therefore, by a due and orderly process of reasoning, we come at last to a false conclusion; it is manifest that all the premises cannot be true; for, were all the premises true, the last conclusion must be so too, by what has been before demonstrated. Now, as to all the other premises made use of in the course of reasoning, they are manifest and known truths by supposition, as being either definitions, self-evident propositions, or truths previously established. The assumed proposition is that only as to which any doubt or uncertainty remains. That alone, therefore, can be false; and indeed, from what has been already shown, must unavoidably be so. And thus we see that, in indirect demonstrations, two contradictory propositions being laid down, one of which is demonstrated to be false, the other, which is always the proposition to be proved, must necessarily be true; so that here, as well as in the direct way of proof, we arrive at a clear and satisfactory knowledge of truth.

10. This is universally the method of reasoning in all apagogical or indirect demonstrations. But if any proposition is assumed from which, in a direct train of reasoning, we can deduce its contradictory; the proposition so assumed is false, and the contradictory one true. For, if we suppose the assumed proposition to be true, then since all the other premises that enter the demonstration are also true, we shall have a series of reasoning consisting wholly of true premises; whence the last conclusion, or contradictory of the assumed proposition, must be true likewise: so that we should thus have two contradictory propositions both true at the same time, which is manifestly impossible. The assumed proposition, therefore, whence this absurdity flows, must necessarily be false; and consequently its contradictory, which is here the proposition deduced from it must be true. If then any proposition is proposed to be demonstrated, and we assume the contradictory of that proposition, and thence directly infer the proposition to be demonstrated; by these very means we know, that the proposition so inferred is true. For since, from an assumed proposition, we have deduced its contradictory, we are thereby certain that the assumed proposition is false; and if so, then its contradictory, or that deduced from it, which in this case is the same with the proposition to be demonstrated, must be true.

11. We have a curious instance of this in the twelfth proposition of the ninth book of the Elements. Euclid there proposes to demonstrate,

that in any series of numbers, rising from unity in geometrical progression, all the prime numbers that measure the last term in the series will also measure the next after unity. In order to this, he assumes the contradictory of the proposition to be demonstrated: namely, that some prime number measuring the last term in the series does not measure the next after unity, and thence, by a continued train of reasoning, proves that it actually does measure it. Hereupon he concludes the assumed proposition to be false; and that which is deduced from it, or its contradictory, which is the very proposition he proposed to demonstrate, to be true. Now that this is a just and conclusive way of reasoning is abundantly manifest from what we have so clearly established above. Whence it appears how necessary some knowledge of the rules of logic is, to enable us to judge of the force, justness, and validity of demonstrations. For, though it is readily allowed, that by the mere strength of our natural faculties we can at once discern that, of two contradictory propositions, the one is necessarily true, and the other necessarily false; yet when they are so linked together in a demonstration, as that the one serves as a previous proposition whence the other is deduced, it does not so immediately appear, without some knowledge of the principles of logic, why that alone, which is collected by reasoning, ought to be embraced as true, and the other, whence it is collected, to be rejected as false.

12. Having thus sufficiently evinced the certainty of demonstration in all its branches, and shown the rules by which we ought to proceed, in order to arrive at a just conclusion, according to the various ways of arguing made use of; it is needless to enter upon a particular consideration of those several species of false reasoning which logicians distinguish by the name of *sophisms*. He that thoroughly understands the form and structure of a good argument, will of himself readily discern every deviation from it. And although sophisms have been divided into many classes, which are all called by sounding names, that therefore carry in them much appearance of learning; yet are the errors themselves so very palpable and obvious, that it would be lost labor to write for a man capable of being misled by them. Here, therefore, we choose to conclude this part of logic; and shall in the next give some account of method, which, though inseparable from reasoning, is nevertheless always considered by logicians as a distinct operation of the mind; because its influence is not confined to the mere exercise of the reasoning faculty, but extends in some degree to all the transactions of the understanding.

PART IV.

OF METHOD.

SECT. I.—OF THE DIFFERENT SPECIES OF METHOD.

1. We have now done with the first three operations of the mind, whose office it is to search after truth, and enlarge the bounds of human knowledge. There is yet a fourth, which regards the disposal and arrangement of our

thoughts, when we endeavour so to put them together as that their mutual connexion and dependence may be clearly seen. This is what logicians call method, and place always the last in order in explaining the powers of the understanding; because it necessarily supposes a previous exercise of our other faculties, and some progress made in knowledge, before we can exert it in any extensive degree.

2. In this view, it is plain that we must be previously well acquainted with the truths we are to combine together; otherwise, how could we discern their several connexions and relations, or so dispose of them as their mutual dependence may require? But it often happens that the understanding is employed, not in the arrangement and composition of known truths, but in the search and discovery of such as are unknown. And here the manner of proceeding is very different. We assemble at once our whole stock of knowledge relating to any subject, and, after a general survey of things, begin with examining them separately and by parts. Hence, though at our first setting out we were acquainted only with some of the grand outlines of truth, we gradually discover the whole: and thus by a narrow scrutiny into things, when we have unravelled any part of knowledge, and traced it to its first principles, so that the whole contexture of it lies open to the view of the mind; here by taking it the contrary way, and beginning with these principles, we can so adjust and put together the parts, as the order or method of science requires.

3. But, as these things are best understood when illustrated by examples, let us suppose any machine, for instance a watch, presented to us, whose structure we are as yet unacquainted with, but want, if possible, to discover. The manner of proceeding in this case is by taking the whole in pieces, and examining the parts separately one after another. When, by such a scrutiny, we have thoroughly informed ourselves concerning each, we then compare them together, in order to judge of their mutual action. Thus we gradually trace out the make and composition of the whole, and come at length to discover how parts of such a form, and so put together, constitute that particular machine called a watch, and contribute to all the several motions observable in it. This discovery being made, we can take things the contrary way, and, beginning with the parts, so dispose and connect them as their several uses and structures require, until at length we have the whole presented to our view.

4. And as in tracing and examining the works of art, so it is in a great measure in unfolding any part of human knowledge; for the relations and mutual operations of things do not always immediately appear upon comparing them together. Hence we have recourse to intermediate ideas, and, by means of them, are furnished with those previous propositions that lead to the conclusion we are in quest of. And, if it so happen that the previous propositions themselves are not sufficiently evident, we endeavour, by new middle terms, to ascertain their truth; still tracing things backward, in

a continual series, until we arrive at some syllogism where the premises are first and self-evident principles. This done, we become perfectly satisfied as to the truth of all the conclusions we have passed through, as they are now seen to stand upon the firm and immovable foundation of our intuitive perceptions: and, as we arrived at this certainty by tracing things backward to their original principles, so may we at any time renew it by a direct contrary process, if, beginning with these principles, we carry our thoughts forward, until they lead us, by a connected chain of proofs, to the very last conclusion of the series.

5. Hence it appears that, in disposing and putting together our thoughts, either for our own use, that the discoveries we have made may at all times lie open to the review of the mind, or where we mean to communicate and unfold the discoveries to others, there are two ways of proceeding equally within our choice; for we may so propose the truths relating to any part of knowledge, as they presented themselves to the mind in the manner of investigation; carrying on the series of proofs, in a reverse order, until they at last terminate in first principles: or, beginning with these principles, we may from them deduce, by a direct train of reasoning, all the several propositions we want to establish. The diversity in the manner of arranging our thoughts gives rise to the two-fold division of method established among logicians; for method, according to their use of the word, is nothing but the order and disposition of our thoughts relating to any subject. When truths are so proposed and put together as they were or might have been discovered, this is called the analytic method, or the method of resolution, as it traces things backward to their source, and resolves knowledge into its first principles. When, on the other hand, they are deduced from these principles, and connected according to their mutual dependence, so that the truths first in order tend always to the demonstration of those that follow; this constitutes what we call the synthetic method: for here we proceed by gathering together the several scattered parts of knowledge, and combining them into one whole, or system, in such a manner that the understanding is enabled distinctly to follow truth through all her different stages and gradations.

6. The first of these two species of method has also obtained the name of the method of invention, because it observes the order in which our thoughts succeed one another in the invention or discovery of truth. The other, again, is often denominated the method of doctrine or instruction; as, in laying our thoughts before others, we generally choose to proceed in the synthetic manner, deducing them from their first principles. For although there is great pleasure in pursuing truth in the method of investigation, because it places us in the condition of the inventor, and shows the particular train and process of thinking by which he arrived at his discoveries; yet it is not so well adapted to the purposes of evidence and conviction. For, at our first setting out, we are commonly unable to divine whither the analysis will lead us, so that

our researches are for some time little better than a mere groping in the dark. And, even after light begins to break in upon us, we are still obliged to make many reviews, and a frequent comparison of the several steps of the investigation among themselves. Nay, when we have unravelled the whole, and reached the very foundation on which our discoveries stand, all our certainty in regard to their truth will be found in a great measure to rise from that connexion which we are now able to discern between them and first principles, taken in the order of composition. But in the synthetic manner of disposing our thoughts, the case is quite different; for as we here begin with the intuitive truths, and advance by regular deduction from them, every step brings evidence and conviction with it; so that, in our progress from one part of knowledge to another, we have always a clear perception of the ground on which our assent rests. In communicating, therefore, our discoveries to others, this method is apparently to be chosen, as it greatly improves and enlightens the understanding, and leads to an immediate perception of truth.

SECT. II.—OF THE UTILITY OF LOGIC.

The logic which for so many ages kept possession of the schools, and was deemed the most important of the sciences, has long been condemned as a mere art of wrangling, of very little use in the pursuit of truth. Attempts have been made to restore it to credit, but without success; and of late years little or no attention whatever has been paid to the art of reasoning in the course of what is called a liberal education. As both extremes are faulty, we cannot conclude this short treatise more properly than with the following reflections on the utility of this science.

If Aristotle was not the inventor of logic, he was certainly the prince of logicians. The whole theory of syllogisms he claims as his own, and as the fruit of much time and labor; and it is universally known, that the later writers on the art have borrowed their materials almost entirely from his *Organon* and Porphyry's *Introduction*. But after men had labored nearly 2000 years in search of truth by the help of syllogisms, lord Bacon proposed the method of induction, as more effectual for that purpose; and since his days the art of logic has gradually fallen into disrepute.

To this consequence many causes contributed. The art of syllogism is admirably calculated for wrangling; and by the schoolmen it was employed, with too much success, to keep in countenance the absurdities of the Romish church. Under their management it produced numberless disputes, and numberless sects, that fought against each other with much animosity, without gaining or losing ground; but it did nothing considerable for the benefit of human life, whilst the method of induction has improved arts, and increased knowledge. It is no wonder, therefore, that the excessive admiration of Aristotle, which continued for so many ages, should end in an undue contempt; and that the high esteem of logic as the grand engine of science should at last make way for too unfavorable an opinion, which

seems now prevalent, of its being unworthy of a place in a liberal education. Men rarely leave one extreme without running into the contrary: those who think according to the fashion will be as prone to go into the present extreme as their grandfathers were to go into the former; and even they who in general think for themselves, when they are offended at the abuse of any thing, are too apt to entertain prejudice against the thing itself. 'In practice,' says the learned Warburton in his *Introduction to Julian, &c.*, 'logic is more a trick than a science, formed rather to amuse than to instruct. And in some sort we may apply to the art of syllogism what a man of wit says of rhetoric, that it only tells us how to name those tools which nature had before put into our hands. In the service of chicane, indeed, it is a mere juggler's knot, now fast, now loose; and the schools where this legerdemain was exercised in great perfection are full of the stories of its wonders.' The authority of Warburton is great; but it may be counterbalanced by another which, on subjects of this nature, is confessedly greater.

'Laying aside prejudice, whether fashionable or unfashionable, let us consider (says Dr. Reid in his *Appendix to lord Kames's Sketch on the Principle and Progress of Reason*), whether logic may be made subservient to any good purpose. Its professed end is to teach men to think, to judge, and to reason with accuracy. No man will say that this is a matter of little importance; the only thing therefore that can admit of doubt is, whether it can be taught?'

'To resolve this doubt, it may be observed, that our rational faculty is the gift of God, given to men in very different measures: Some have a large portion, some a less; and, when there is a remarkable defect of the natural power, it cannot be supplied by any culture. But this natural power, even where it is the strongest, may lie dead for want of the means of improvement. Many a savage may have been born with as good faculties as a Newton, a Bacon, or an Aristotle; but their talents were buried by having never been put to use, whilst those of the philosophers were cultivated to the best advantage. It may likewise be observed, that the chief means of improving our rational power is the vigorous exercise of it in various ways and on different subjects, by which the habit is acquired of exercising it properly. Without such exercise, and good sense also, a man who has studied logic all his life may be only a petulant wrangler, without true judgment or skill of reasoning in any science.'

This must have been Locke's meaning, when, in his *Thoughts on Education*, he says, 'If you would have your son to reason well, let him read *Chillingworth*.' The state of things is much altered since Locke wrote: logic has been much improved, chiefly by his writings; and yet much less stress is laid upon it, and less time consumed in its study. His counsel, therefore, was judicious and seasonable: to wit, that the improvement of our reasoning power is to be expected much more from an intimate acquaintance with the authors who reason best, than from studying voluminous systems of school

logic. But if he had meant, that the study of logic was of no use, nor deserved any attention, he surely would not have taken the pains to make so considerable an addition to it, by his *Essay on the Human Understanding*, and by his *Thoughts on the Conduct of the Understanding*; nor would he have remitted his pupil to *Chillingworth*, the acutest logician as well as the best reasoner of his age.

There is no study better fitted to exercise and strengthen the reasoning powers than that of the mathematical sciences; because there is no other branch of science which gives such scope to long and accurate trains of reasoning, or in which there is so little room for authority or prejudice of any kind to give a false bias to the judgment. When a youth of moderate parts begins to study Euclid, every thing is new to him: his apprehension is unsteady, his judgment is feeble, and rests partly upon the evidence of the thing, and partly upon the authority of his teacher. But every time he goes over the definitions, the axioms, the elementary propositions, more light breaks in upon him; and, as he advances, the road of demonstration becomes smooth and easy: he can walk in it firmly, and take wider steps, till at last he acquires the habit, not only of understanding a demonstration, but of discovering and demonstrating mathematical truths.

It must indeed be confessed, that a man without the rules of logic may acquire a habit of reasoning justly in mathematics, and perhaps in any other science. Good sense, good examples, and assiduous exercise, may bring a man to reason justly and acutely in his own profession without rules. But whoever thinks, that from this concession he may infer the inutility of logic, betrays, by this inference, a great want of that art; for he might as well infer, because a man may go from London to Edinburgh by the way of Paris, that therefore any other road is useless.

There is perhaps no art which may not be acquired, in a very considerable degree, by example and practice, without reducing it to rules. But practice joined with rules may carry a man forward in his art farther and more quickly than practice without rules. Every ingenious artist knows the utility of having his art reduced to rules, and thereby made a science. By rules he is enlightened in his practice, and works with more assurance. They enable him sometimes to correct his own errors, and often to detect the errors of others; and he finds them of great use to confirm his judgment, to justify what is right, and to condemn what is wrong. Now mathematics are the noblest praxis of logic. Through them we may perceive how the stated forms of syllogism are exemplified in one subject, namely the predicament of quantity; and by marking the force of these forms, as they are there applied, we may be enabled to apply them of ourselves elsewhere. Whoever, therefore, will study mathematics with this view, will become, not only by mathematics a more expert logician, and by logic a more rational mathematician, but a wiser philosopher, and an acuter reasoner, in all the possible subjects either of science or deliberation. But when mathematics,

instead of being applied to this excellent purpose, are used, not to exemplify logic, but to supply its place; no wonder if logic fall into contempt, and if mathematics, instead of furthering science, become in fact an obstacle. For when men, knowing nothing of that reasoning which is universal, come to attach themselves for years to a single species, a species wholly involved in lines and numbers, the mind becomes incapacitated for reasoning at large, and especially in the search of moral truth. The object of mathematics is demonstration; and whatever, in that science, is not demonstration, is nothing, or at least below the sublime enquirer's regard. Probability, through its almost infinite degrees, from simple ignorance up to absolute certainty, is the terra incognita of the mathematician. And yet here it is that the great business of the human mind is carried on, in the search and discovery of all the important truths which concern us as reasonable beings. And here, too, it is, that all its vigor is exerted; for, to proportion the assent to the probability accompanying every varying degree of moral evidence, requires the most enlarged and sovereign exercise of reason.

In reasonings of this kind, will any man pretend that it is of no use to be well acquainted with the various powers of the mind by which we reason? Is it of no use to resolve the various kinds of reasoning into their simple elements; and to discover, as far as we are able, the rules by which these elements are combined in judging and in reasoning? Is it of no use to mark the various fallacies in reasoning, by which even the most ingenious men have been led into error? It must surely betray great want of understanding, to think these things useless or unimportant. Now these are the things which logicians have attempted; and which they have executed—not indeed so completely as to leave no room for improvement, but in such a manner as to give very considerable aid to our reasoning powers. That the principles they have laid down with regard to definition and division, with regard to the conversion and opposition of propositions, and the general rules of reasoning, are not without use, is sufficiently apparent from the blunders committed daily by those who disdain any acquaintance with them.

Although the art of categorical syllogism is confessedly little fitted for the discovery of unknown truth, it may yet be employed to excellent purpose, as it is perhaps the most compendious method of detecting a fallacy. A man in quest of unknown truths must generally proceed by the way of induction, from effects to causes; but he who, as a teacher, is to inculcate any system upon others, begins with one or more self-evident truths, and proceeds, in the way of demonstration, to the conclusion which he wishes to establish. Now every demonstration may be resolved into a series of syllogisms, of which the conclusion of the preceding always enters into the premises of that which follows; and if the first principles be clear and evident, and every syllogism in some legitimate mode and figure, the conclusion of the whole must infallibly be admitted. But, when the demonstration is thus

broken into parts, if we find that the conclusion of one syllogism will not, without altering the meaning of the terms, enter legitimately into the premises of that which should immediately follow; or, supposing it to make one of the premises of a new syllogism, if we find that the conclusion resulting from the whole series, thus obtained, is different from that of the demonstration; we may, in either of these cases, rest assured that the author's reasoning is fallacious, and leads to error; and that, if it carried an appearance of conviction before it was thus resolved into its elementary parts, it must have been owing to the inability of the mind to comprehend at once a long train of arguments. Whoever wishes to see the syllogistic art employed for this purpose, and to be convinced of the truth of what we have said respecting its utility, may consult the excellent writer recommended by Locke, who, in places innumerable of his incomparable book, has, without pedantry, even in that pedantic age, made the happiest application of the rules of logic for detecting and exposing the sophistry of his Jesuitical antagonist.

On the whole then, though we acknowledge that much time was wasted by our forefathers in syllogistic wrangling, which may be termed the mechanical part of logic, yet the art of forming and examining arguments is certainly an attainment well worthy the ambition of that being whose highest honor is to be endued with reason.

SECT. III.—DR. BROWN'S VIEW OF THIS SCIENCE.

The following is a condensed view of the general pretensions of the Aristotelian logic from Lectures on the Philosophy of the Human Mind by Dr. Brown, late professor of moral philosophy in the university of Edinburgh. In the condemnation of the science he may be found too severe and indiscriminating in the opinion of some of our readers, but his great and just fame as a metaphysician entitles him to a hearing.

Reasoning according to this author, then is nothing more than a number of propositions, consecutive in a certain order: it is a continued series of analytic operations developing the elements of our thought. In every proposition, that which is affirmed is a part of that of which it is affirmed, and the proposition, however technical its language may be, expresses only the single feeling of this relation. When I say snow is white, I state one of the many feelings which constitute my complex notion of snow. When I say man is fallible, I state one of the many imperfections which enter into my complex notion of man. The statements of one particular relation are simple propositions, in each of which a certain analysis is involved. But, when I reason, or add proposition to proposition in a certain series I merely prosecute my analysis, and prosecute it more or less minutely, according to the length of the ratiocination. When I say man is fallible, I state a quality involved in the nature of man, as any other part of an aggregate is involved in any

other comprehending whole. When I add, he may therefore err, even when he thinks himself least exposed to error, I state what is involved in the notion of his fallibility. When I say, he therefore must not expect that all men will think as he does, even in points which appear to have no obscurity, I state that which is involved in the possibility of his and their erring even on such points. When I say, that he therefore should not dare to punish those who merely differ from him, and who may be right even in differing from him, I state what is involved in the absurdity of expecting that all men should think as he does. And when I say, that any particular legislative act of intolerance is as unjust as it is absurd, I state only what is involved in the impropriety of attempting to punish those who have no other guilt than that of differing in opinion from others, who are confessedly of a nature as fallible as their own.

In all this reasoning, though composed of many propositions, there is obviously only a progressive analysis, with a feeling, at each step, of the relation of parts to the whole, the predicate of each proposition being the subject of a new analysis in the proposition which follows it. Man is fallible. He who is fallible may err, even when he thinks himself least exposed to error. He who may be in error, even when he thinks himself safest from it, ought not to be astonished that others should think differently from him, even on points which may seem to him perfectly clear; and thus, successively, through the whole ratiocination, the predicate becomes in its turn a subject of new analysis, till we arrive at the last proposition, which is immediately extended backwards to the primary subject of analysis, man,—as involved in that which is itself involved in the primary complex conception, or aggregate of many qualities.

If reasoning be nothing more than a number of propositions, consecutive in a certain order of mutual relation between the subjects and predicates, what are we to think of that art of reasoning, which, for so many ages, banished reason from the schools; of that art which rendered it so laborious a drudgery to be a little more ignorant than before; which could produce so much disputation without any subject of dispute, and so many proud victories of nothing over less than nothing! Such was the scholastic art of logic: an art which was held out, not so much as an auxiliary to reason, as with the still higher praise of being an instrument that might almost supply its place, and by the possession of which the acute and accurate might argue still more acutely and accurately, and imbecility itself become a champion worthy of encountering them; and, though not perhaps the victor, at least not always the vanquished.

That there may be, or rather that there is, a rational logic, we are far from denying; and that many useful directions, in conformity with a certain system of rules, may be given to the inexperienced student that may facilitate to him acquisitions of knowledge which, but for such directions, he would have made only more slowly, or perhaps not made at all. The art of reasoning, however, which a judicious logic affords, is

not so much the art of acquiring knowledge as the art of communicating it to others, or recording it in the manner that may be most profitable for our own future advancement in the track which we have been pursuing. Its direct benefit to ourselves is rather negative than positive—teaching us the sources of error in our mental constitution, and in all the accidental circumstances of the language which we are obliged to use, and the society in which we must mingle,—and thus rather saving us from what is false, than bestowing on us what is true. Indeed, since we cannot produce directly in our mind any one conception, or any one feeling of relation, it is very evident that the influence of any art of reasoning on our trains of thought must be indirect only.

But, if an art of reasoning is to be given to us, it ought surely to be an art which will render the acquisition of knowledge more easy, not more difficult; an art which is to avail itself of the natural tendency of the mind to the discovery of truth, not to counteract this tendency, and to force the mind, if it be possible, to suspend the very progress which was leading it to truth. With which of these characters did the syllogistic logic more exactly correspond?

The natural progress of reasoning has been already explained and illustrated. One conception follows another conception, according to certain laws of suggestion (commonly termed *association*) to which our divine Author has adapted our mental constitution; and by another set of laws, which the same divine Author has established, certain feelings of relation arise from the consideration of the suggesting and suggested object. This is all in which reasoning as felt by us consists. We have the conception of A, it suggests B, and, these two conceptions co-exerting, we feel some relation which they bear to each other; B, thus suggested, suggests C, and the relation of these is felt in like manner; and thus through the longest ratiocination, analytical or proportional, each subject of our thought suggests something which forms a part of it and is involved in it, or something which has to it a certain relation of proportion; and the relation of comprehension in the one case, or of proportion in the other case, is felt accordingly at every step. Nothing surely can be simpler than a process of this kind; and it is not easy to conceive how the process could be made shorter than nature herself has rendered it, unless every truth were known to us by intuition. (Objects and the relations of objects—these are all which reasoning involves; and these must always be involved in every reasoning. While reasoning, then, or a series of propositions, is necessary for the development of truth, the intervening conceptions which form the subjects of those propositions that connect one remote conception with another must arise successively in the mind, and their relations be felt in like manner, successively. What is it which the syllogistic art would confer on us in addition? To shorten the process of arriving at truth, it forces us to use, in every case, three propositions instead of the two which nature directs us to use. Instead of allowing us to say man is fallible he may

therefore err even when he thinks himself most secure from error, which is the spontaneous order of reasoning, the syllogistic art compels us to take a longer journey to the same conclusion, by the use of what is called a major proposition, a proposition which never rises spontaneously, for the best of all possible reasons, that it cannot rise without our knowledge of the very truth which is by supposition unknown. To proceed in the regular form of a syllogism, we must say, all beings that are fallible may err, even when they think themselves most secure from error. But man is a fallible being: he may therefore err, even when he thinks himself most secure from error. In our spontaneous reasonings, in which we arrive at precisely the same conclusions, and with a feeling of evidence precisely the same, there are, as we have said, no major propositions, but simply what, in this futile art, are termed technically the minor and the conclusion. The invention and formal statement of a major proposition, then, in every case, serve only to retard the progress of discovery, not to quicken it, or render it in the slightest degree more sure.

This retardation of the progress of reasoning is one circumstance which distinguishes the syllogism; but the absurdity, which is implied in the very theory of it, distinguishes it still more. It constantly assumes, as the first stage of that reasoning by which we are to arrive at a particular truth, our previous knowledge of that particular truth. The major is the very conclusion itself under another form, and its truth is not more felt than that which it professes to develop. Thus to take one of the many trifling examples which, in books of logic, are usually given, with a most appropriate selection, to illustrate this worse than trifling art, when, in order to prove that John is a sinner, I do not adduce any particular sin of which he has been guilty, but draw up my accusation more irresistibly, by the major of a syllogism. All men are sinners: John is a man: therefore John is a sinner. If I really attached any meaning to my major proposition, all men are sinners, I must, at that very moment, have felt as completely that John was a sinner, as after I had pursued him technically through the minor and conclusion.

The great error of the theory of the syllogism, consisted in supposing that, because all our knowledge may be technically reduced, in some measure, to general maxims, these maxims have naturally a prior and paramount existence in our thought, and give rise to those very reasonings which, on the contrary, give rise to them. It is not on account of our previous assent to the axiom, A whole is greater than a part,—that we believe any particular whole to be greater than any part of it; but we feel this truth in every particular case, by its own intuitive evidence, and the axiom only expresses briefly our various feelings of this kind without giving occasion to them. The general axiom is, in every case, posterior to the separate feeling of which it is only the brief expression, or at least without which, as prior to our verbal statement of the axiom, the axiom itself never could have formed a part of our system of knowledge. The syllogism therefore, which proceeds from the axiom to the de-

monstration of particulars, reverses completely the order of reasoning, and begins with the conclusion in order to teach us how we may arrive at it.

The natural process of reasoning, by two propositions, instead of the three which the syllogism would force us to use, has been allowed, indeed, by logicians to have a place in their system; because, with all their fondness for their own technical modes and figures, they had not quite sufficient hardihood to deny, that it is at least possible for us to reason sometimes, as in truth we always reason. Their only resource, therefore, was to reduce this natural process under their own artificial method, and to give it a name which might imply the necessity of this reduction, before the reasoning itself could be worthy of that honorable title. They supposed, accordingly, the proposition, which was technically wanting, to be understood in the mind of the thinker or hearer, and termed the reasoning, therefore, an enthymeme. It was, they said, a truncated or imperfect syllogism. They would have expressed themselves more accurately, if they had described their own syllogism, as, in its relation to the natural process of our thought, a cumbrous and overloaded enthymeme.

These remarks, though relating chiefly to the influence of this technical process, as a supposed mode of facilitating the acquisition of knowledge in our own meditative reasonings, show that if the syllogism was inefficacious, and worse than inefficacious as a process for discovering truth, it was not less inadequate as an instrument for communicating truth to others. A very little attention to the nature of the different propositions of the syllogism will be sufficient to show that the same fundamental error, which renders it useless for discovering truth, renders it equally useless for the development of it: and that, as our internal reasoning is only a series of enthymemes, it is only by such a series of enthymemes as that by which truth unfolds itself to our own minds that it can be successfully unfolded to the minds of others. As a mode of communicating knowledge the syllogism is indeed, if possible still more defective than as a mode of acquiring it. It does not give any additional knowledge, nor communicate the knowledge which it does communicate in any simpler, or shorter, or surer way. On the contrary, whatever knowledge it gives it renders more confined by being more cumbrous; and it cannot fail to train the mind which receives instruction this way to two of the most dangerous practical errors,—the errors of admitting, without proof, only what requires proof, and of doubting, that is to say, of requiring proof, only of what is evident. Such is the syllogism, considered as an instrument, either for facilitating our attainments in knowledge, or for communicating those attainments unto others.

The triumph of the syllogistic art, it must be confessed, however, is not as an art of acquiring or communicating truth, but as an art of disputation,—as the great art of proving any thing by any thing, quidlibet per quodlibet probandi. And if it be a merit to be able to dispute long and equally well, on subjects known and unknown, to vanquish an opponent by being in the wrong, and

sometimes too by being in the right, but without the slightest regard either to the right or the wrong, and merely as these accidental circumstances may have corresponded with certain skilful uses of terms without a meaning,—this merit the logicians of the schools unquestionably might claim. Indeed in controversies of this sort, in those ages of endless controversy, success, as has been very truly remarked, 'tended no more to decide the question, than a man's killing his antagonist in a duel serves now to satisfy any person of sense that the victor had right on his side, and that the vanquished was in the wrong.'

Of the direct influence of the school logic in retarding, and almost wholly preventing, the progress of every better science, it is unnecessary to attempt any additional illustration after the remarks already offered, and the masterly views of the subject presented by the great lord Bacon. But the indirect influence of this art was not less hurtful.

One of the most hurtful consequences of this method was the ready disguise of venerable ratiocination which it afforded for any absurdity. However futile an explanation might be, it was still possible to advance it in all the customary solemnities of mood and figure; and it was very natural, therefore, for those who heard what they had been accustomed to regard as reasoning to believe, that, in hearing a reasoning, they heard a reason.

Another very hurtful consequence of this technical system was, that the constant necessity of having recourse to some syllogistic form of argument, and of using these forms in cases in which the opinions involved in the syllogism were as clear before the syllogism as after it, rendered argument and belief, by a sort of indissoluble association, almost synonymous terms. If we had still to prove John to be fallible, after having proved, or at least obtained assent to the proposition, that all men are fallible, it was not easy to discover any truth so self-evident as not to stand, at least equally, in need of demonstration. Hence the constant tendency in the scholastic ages to prove what did not stand in need of proof. Every thing was *to be* demonstrated, and every thing *was* demonstrated; though it must be confessed the only effect of the demonstration frequently was to render obscure (as obscure as any thing self-evident could be rendered), what, but for the demonstration, could not have admitted of the slightest doubt.

Akin to this tendency of proving every thing, even self-evident propositions, by some syllogistic form, was the tendency which the mind acquired to apply many varieties of technical phraseology to the same proposition, so as to make

many propositions of *one*, as if every repetition of it, in another form of language, were the enunciation of another truth. It is impossible to read a single page of the old logicians without discovering innumerable examples of this. Indeed as the forms of technical expression, or at least the possible combinations of them are almost infinite, it is, in many cases, difficult to discover what principle of forbearance and mercy to the reader led the logician to stop at one of his identical propositions, rather than to extend the supposed ratiocination through many similar pages. There can be no doubt that the principle which produced many pages might with as much reason have produced as many volumes.

The reign of this philosophy may now be considered, like the age of Chivalry, as gone; for it is scarcely necessary to speak of a few admirers of the Aristotelian logic who have not yet vanished from among us, who love what is very ancient and what is written in Greek, and who have therefore two irresistible reasons for venerating that philosophy which is unquestionably much older than Newton, or Des Cartes, or Bacon, and as unquestionably written in language which saves it from vulgar eyes. Or, to speak with more candor of such misplaced sages of other times, there may perhaps be some few generous, but erring, lovers of wisdom, who, impressed with the real merits of Aristotle, and with the majesty of that academic sway, which he exercised for so long a period of the history of our race, give him credit for merit still greater and more extensive than he really possessed; but merit it must, at the same time, be acknowledged, which was long as indisputable as his real excellence, and which all the learned and honored, of every nation, in which learning could confer honor, united in ascribing to him, and gloried in being his worshippers. The worship, however, is now past, but there are effects of the idolatry which still remain. We have laid aside the superstition, but, as usually happens where superstition has reigned, we have retained many of the superstitious practices.

That we reason worse than we should have done, if our ancestors had reasoned better, there can be no doubt, because we should have profited by the results of their better reasoning; but there can be almost as little doubt that we suffer from their errors, in another way, by having imbibed some portion of the spirit of their dialectic subtleties; some greater passion for distinctions merely verbal, and more laborious demonstrations of things self-evident, than we should have felt from the mere imperfection of our intellectual nature, if the logic of Aristotle had never existed.

LOGWOOD, *n. s.* From *Laguna*, in the bay of Campeachy. A dye-wood: a species of *HÆMATOXYLON*, which see.

To make a light purple, mingle ceruse with Logwood water. *Peacham.*

Logwood is of a very dense and firm texture: and is the heart only of the tree which produces it. It is very heavy, and remarkably hard, and of a deep, strong red colour. It grows both in the East and

West Indies, but no where so plentifully as on the coast of the bay of Campeachy. *Hill's Mat. Med.*

LOGWOOD. See *HÆMATOXYLON*. Logwood is used in great quantities for dyeing purple, and more especially black. All the colors, however, which can be prepared from it, are of a fading nature, and cannot, by any art, be made equally durable with those prepared from some other materials. Of all the colors prepared from log-

wood, the black is the most durable. Dr. Lewis recommends it as an ingredient in making ink. Logwood is also found to have a considerable astringent virtue as a medicine, and an extract of it is sometimes given with great success in diarrhoeas. See DYEING.

LOHAGHUR, or the Iron Fort, is a celebrated fortress of Hindostan, in Dowletabad, and stands on a rock nearly perpendicular, of great height, and surrounded by a double stone wall. It is also well supplied with water, and has extensive magazines and store rooms in the solid rock. It belongs to the British, who took it not long since from the paishwa, and is about twenty miles north-west of Poona.

LOHEIA, a city of Yemen, Arabia, on the coast of the Red Sea, and at the bottom of a capacious but shallow bay. A large island, and a group of smaller ones, are a barrier against the sea to the north-west. It is defended by several towers, which admit cannon, and many of the houses are built of stone; but the greater number are mud huts. Vessels can only anchor at a distance from the town; and at low water heavy laden boats cannot approach. The trade is in a second rate species of coffee of inferior quality. Goods brought direct from India pay a duty of five per cent. here: all goods brought down the Red Sea, seven per cent.; and presents are necessary to a good understanding with the authorities. The water is bad, and the surrounding country desolate.

LO'HOCK, *n. s.* Fr. *lohoc, loch*. 'An electuary that is licked, not chewed, nor divided by the teeth,—Minsheu.

Lohock is an Arabian name for those forms of medicine which are now commonly called eclegmas, lambatives, or linctuses. *Quincy.*

Lohocks and pectorals were prescribed, and venesection repeated. *Wiseman's Surgery.*

LOIN, *n. s.* Sax. *lenð*; Belg. *longie*; Ital. *longea*; Fr. *longe*. The back of an animal. In the plural, the reins of man: metaphorically, any source of progeny or production.

Thou slander of thy heavy mother's womb!
Thou loathed issue of thy father's loins!

Shakspeare.

My face I'll grime with filth,

Blanket my loins. *Id. King Lear.*

Shall these hands destroy the fruits of mine own loins?

Bp. Hall.

A multitude! like which the populous north
Poured never from her frozen loins, to pass
Rhene, or the Danaw, when her barbarous sons
Came like a deluge on the south. *Milton.*

LOIR, a river of France, which rises at Cernay, in the arrondissement of Chartres, department of the Eure et Loire. It begins to be navigable for floats at Ponce, and for vessels at Coësmont, near Chateau du Loir, in the department of Sarthe. In its course, which is about 165 miles, it receives the Ozanne the Couie, the Braye, the Long, the One, and several small rivers.

LOIR-ET-CHER, a department of France, bounded on the north-west by that of the Sarthe, north-east by that of the Loiret, south by that of the Indre, south-east by that of the Cher, and south-west by that of the Indre-et-Loire. It is formed of part of the Blaisois and the Sologne,

a dependency of the old province of Orleannais, and derives its name from the two rivers: the Loir, which flows into it from the north toward the east, and the Cher, which runs from east to west. The chief place in this prefecture is Blois: it contains three arrondissements; Blois, containing 111,075 inhabitants; Romarantin 43,624; and Vendome 72,828; being a total population of 227,527, on a surface of 2871 square miles. These are subdivided into twenty-four justiciaries of the peace, or cantons, and 309 communes, with a territorial revenue of 11,721,000 francs. It is in the fourth military division, belongs to the diocese and royal court of Orleans, and is divided into two electoral arrondissements, sending three members to the chamber of deputies.

This is almost entirely a level country, having very few hills; the Loire, in its course, divides it into two very distinct parts: that on the left bank, which is nearly covered with marshes, pools, extensive forests, uncultivated and sandy lands, where scarcely any thing but buck-wheat will grow; while that on the right bank of the river presents an appearance of the greatest fertility, being composed of rich and well cultivated plains, hills covered with vineyards, and beautiful verdant meadows. A long line of small hills, planted with vines and fruit trees, extends through the whole course of the river, on the borders of which are seen handsome residences, and villages shaded with groves of trees. The climate is generally mild and temperate, and the air pure and healthy, with the exception of some parts near Romarantin, from the marshes of which unwholesome exhalations arise. The soil is chalky, but produces more than sufficient for its inhabitants. It contains 66,324 hectares of forest land (chiefly oaks and hornbeams), and 28,000 hectares of vineyards. The average produce of a hectare of arable land amounts to 17 francs 15 centimes. It yields all kinds of grain, especially wheat and buck-wheat, chestnuts, fruits, and vegetables of every description; a great quantity of fine hemp, wines of excellent quality, mulberry trees, wood, and good pasturage. There is abundance of game, as red partridges, foxes, and wolves; the rivers are well stocked with fish, especially trout, carp, crabs, &c.; numerous flocks of sheep, and herds of horned cattle, good horses, and poultry of all sorts, abound here, as well as silk-worms and bees. It has a large nursery, a royal dépôt of standard measures at Blois, iron-mines, quarries of alabaster, freestone, flint (supplying all France with gun-flints), marble, potter's earth, and turf. The inhabitants carry on the manufacture of coarse woollen cloths, cotton, fringes, cotton counterpanes, woollen caps, leather gloves, and cutlery. They have also refining houses for sugar, procured from beet-root, spinning mills for woollen and cotton yarn, worked by water, tan-yards, glass-houses, deftories, forges, &c.; and trade in grain, wines, Orleans brandy, vinegar, wood for building and for fuel, cattle, iron, flint stones, &c. The principal rivers which water this department are the Loire and the Cher, which are navigable in this part of their course; the Loir; the Beuvron; the Cosson; and the Sauldre; it is crossed by the great roads of Tours, Châteaudun, and Orleans.

LOIRE, one of the principal rivers of France for the length of its course, rises in Mount Gerbier-le-Joux, near the village of Sainte Eulalie, in the department of Ardeche, watering a vast plain of more than 600 miles, and dividing France almost into two equal parts. It establishes a communication between the Atlantic Ocean and the Mediterranean Sea, by means of the central canal, and facilitates the commercial operations of a great number of cities in the kingdom. At first this majestic river is closely shut up between the romantic mountains of the Vivarais, then crossing Velay, Forez, Berry, and Nivernais, it directs its course a little from the south-east to the north-west, as far as Orleans: below that city it flows directly westward through the middle of a fertile vale, bordered with woody elevations, and hills planted with vines, at the foot of which are extensive and beautiful plains. Numerous hamlets, villages, towns, cities, and chateaus, adorn its banks, while the multitude of boats that skim over its waters contribute to give life to this charming country. Standing on the bridge at Blois, and looking towards its source, the most magnificent prospect presents itself of hills and woods, towns, villages, country houses, and insulated towers, in a vast amphitheatre of nearly twenty miles.

The Loire presents no uniform or clear channel for navigation; the shifting of the sands, from one side to the other, constantly varies the course that the boats must pursue. It has been found necessary, therefore, to construct dikes in some parts, both for the purpose of collecting its waters in the dry season, and confining them in times of great increase. These embankments are generally about twenty feet high, and twenty-four feet broad at the top; in parts where they are most exposed to the shock of the waters, they are capped with masonry. The middle of this causeway is also paved almost through its whole length, and presents one of the finest roads in the world, bordered with rows of poplars. This river begins to be passable for rafts, carrying fir trees for boat-building at Retournac, in the department of the Upper Loire; it is then navigable for other vessels from La Noirie, in the department of the Loire, to Roanne, where the greater part of the merchandise of Lyons, Languedoc, Provence, and Dauphiny, is embarked. The chief of these are grain, wines, brandy and other spirits, liqueurs, oils, southern fruits, colonial commodities, salt, wool, hemp, forged and cast iron, small copper vessels, pit-coal, wood for ship-building, ropes, resin, tar, &c. The mean height of water varies from 1 metre 95 centimes, to 2 metres 90 centimes, and their fall is about 1 metre in every 200. A sort of boats has lately been established on the Loire, called flies, which regularly proceed from Nantes to Orleans, completing the voyage in about a fortnight.

After passing by Nevers, Chatillon, Chateaufort, Orleans, Blois, Tours, Saumur, Nantes, and many other considerable places, the Loire falls into the ocean just below St. Nazaire; its course being about 660 miles, and receiving the waters of the Arroux, the Bebre, the Arnon, the Nièvre, the Allier, the Cher, the Indre, the Vienne, the Thouet, the Authion, the Mayenne, the Sevre-

Nantaise, the Erdre, the Acheneau, and many other smaller tributary streams. Its mouth is in a very bad state, occasioned by the formation of a sand-bank about a mile and a half from the anchorage, where the water is not more than seven or eight feet deep at low tide, while formerly it was more than twenty.

LOIRE, THE, a department of France, is formed out of the Forey, a dependency of the former province of Lyonnais, and takes its name from the above river, which crosses it from south to north. The chief place of this prefecture is Montbrison: it has three arrondissements, Montbrison, containing 114,607 inhabitants; Roanne 107,808; and St. Etienne 121,139; being a total population of 343,554 souls, on an area of 732 square miles, and yielding a revenue of 14,368,000 francs. It is situated in the nineteenth military division, has twenty-eight cantons, and 327 communes, a royal court and a bishop's see at Lyons, is divided into three electoral arrondissements, and sends five members to the chamber of deputies. This department is bounded on the north by that of the Saone et Loire; on the east by that of the Rhone; on the south by those of Ardeche and the Upper Loire; and on the west by those of Puy de Dôme and the Allier.

It consists of beautiful and fertile plains on both banks of the Loire, and lofty mountains, which surround it on the north, south, and west; the soil is for the most part poor and stony. On these mountains, the highest point of which is Mount Pilat, are to be found some excellent pastures, feeding a great number of cattle, and excellent cheeses are made in these places; some of them are cultivated to a certain height, others are covered with vines, producing wines of good quality; and abundance of chestnut trees, the fruit of which is sold at Paris under the name of Lyons chestnuts. This rocky soil is cultivated mostly with horses and mules, but the produce is far from sufficient for its inhabitants; the country contains about 36,386 hectares of forests, chiefly of oaks, beech, and firs; and 13,000 hectares of vineyards, each hectare of arable land yielding on an average twenty-four francs ninety centimes. The productions consist of all kinds of grain, excellent potatoes, fine chestnuts, good fruits, a quantity of hemp, dyers' weed, madder, saffron, every sort of mountain plants, wine, and wood. It abounds in roe-bucks, hares, thrushes, and aquatic birds; pools full of fish; mules, horses, horned cattle, sheep (famous for the delicacy of their meat), and great numbers of goats, and poultry. This department also contains mines of iron, lead, natural steel, and black emery, besides quarries of marble, granite, porphyry, whetstones, gun-flints, &c. At St. Alban, and Sail-en-Cousan, are some fine mineral springs. The inhabitants have considerable manufactories of arms of all kinds, ironmongery, hempen cloths, calicoes, cambrics, coarse cloths, lace, silk, ribands and shoe-laces, haberdashery, crapes, glue, lamp-black, cast and wrought iron, files, saw-blades, locks, fencing foils, knives, and nails. There are also many cotton spinning manufactories, paper-mills, numerous and large glass-houses, silk-mills, iron works, lime, plaster,

brick and tile kilns, dye-houses, tan-yards, and factories for the preparation of chamois leather. There is likewise a royal manufactory of arms. Their trade consists in coal, iron and iron wares, arms, nails, leather, paper, silk, ribands, wood for boat-building, chestnuts, and the famous cheeses called *La Roche* cheeses.

The principal rivers are the Loire, which is here navigable, the Lignon, the Ysable, the Aax, the Semene, the Coise, the Faran, and the Gier; and this department is crossed by the great roads of Lyons, Clermont, and Moulins.

LOIRE, UPPER, a department of France, comprising the Velay and that part of the Cevennes dependent on the former province of Languedoc, derives its name from its situation with regard to the river Loire, which flows through it from the south to the north-east. The principal place of this prefecture is Le Puy; it contains three arrondissements, Le Puy, with 122,717 inhabitants; Briouda 78,227; and Yssengeaux 75,677; constituting a total population of 276,621 souls, on an area of 2196 square miles; twenty-eight cantons, and 272 communes. It yields a revenue of 10,400,000 francs, is in the nineteenth military division, has a royal court at Riom, and a bishop's see at St. Flour: it is divided into two electoral arrondissements, and sends three members to the chamber of deputies. It is bounded on the north by the departments of the Loire and the Puy de Dome; on the east by that of Ardèche; on the south by that of Lozère; and on the west by that of Cantal.

This department is entirely covered with basaltic mountains, the tops of which are covered with snow during more than six months of the year, and on the sides of them are extensive forests, enclosing excellent pastures, which feed a great number of cattle, and mules. Some of the smaller hills are covered with chestnut trees and vines, cultivated with great care. In the valleys are found plains of small extent, and yet more fertile than might be expected from their wild situation; they yield abundance of excellent fruit for the Paris market, and a quantity of good corn. The soil is naturally very fertile, especially in the valleys and on the hills: it is almost every where of the same quality, consisting of volcanic earth, lava, and pumice-stone of all kinds. In the mountains are to be perceived the remains of ancient volcanoes; streams of lava and strange collections of basaltic columns cover their sides, and extend to their feet, presenting a most singular spectacle. The soil, being rocky, is cultivated with mules, and yields a full supply for its inhabitants; there are 36,386 hectares of forest land, and 13,000 of vineyards: the mean produce of each hectare of arable land is eighteen francs fifty-nine centimes.

Here are mines of antimony and pit-coal, and quarries of statuary marble, granite, mill-stones, freestone, plaster, and gray stone. The manufactures consist of black and white lace, thread, silk, blond, ribands, woollen counterpanes, common stuffs, nails, organzine silk, and fullers' earth. They have also considerable dye-houses, tan-yards, paper-mills, sand-pits, lime-kilns, &c. An extensive trade is carried on in grain, vegetables, mules, cattle, lace, leather, and paper. This

country is watered by the Allier, which is navigable, the Loire, the Ance, the Auzon, the Alagnon, and the Arcueil.

LOIRE-INFÉRIEURE, a department of France, is formed of part of the former province of Upper Bretagne, and takes its name from the natural course of the Loire, which crosses it from east to west, and here empties itself into the ocean. The principal place of this prefecture is Nantes: it is divided into five arrondissements, Nantes, containing 187,435 inhabitants; Ancenis 45,234; Chateau Briant 57,237; Paimbœuf 39,394; and Savenay 104,515: being a total population of 433,815 souls, on a superficial extent of 3168 miles: it has forty-five cantons and 209 communes, yielding a revenue of 18,904,000 francs: it is in the twelfth military division, has a royal court at Rennes and a bishopric at Nantes, and consists of four electoral arrondissements, which send six members to the chamber of deputies. Its boundaries are, the department of Morbihan to the north-west; that of Ille-et-Vilaine to the north; that of Maine-et-Loire to the east; that of La Vendée to the south; and the ocean to the west.

The territory of this maritime department is intersected by an incredible number of rivers, several of which are navigable. It has a coast of sixty miles in extent, which the inroads of the sea are continually increasing in some parts. The soil, generally level, presents a multitude of delightful situations and various scenery, and produces grain of all kinds; the pasturage is excellent, and furnishes feeding for great numbers of cattle and horses; extensive forests, heaths, marshes, meadows planted with fruit trees, and rich vineyards spread over the surface of this country. The salt marshes, which stretch along the coast, are very productive and of considerable importance to the inhabitants. In the southern part is the lake Grand Lieu, one of the largest in France, and abounding in fish; there is also another formed by the Erdre, which for nearly twenty miles widens into a stream between seven and eight miles broad; this lake is very beautiful, being surrounded by verdant hills, planted with chestnut trees and peopled with villages and country houses. This country is cultivated with the aid of horses, and yields a sufficiency for its inhabitants, containing 37,452 hectares of forest land, chiefly oaks, beech, and birch, and 45,000 hectares of vineyards, producing on an average twenty-nine francs eighty-nine centimes per hectare of arable land. There are mines of iron, antimony, pewter, loadstone, and fine coal; and quarries of marble, granite, freestone, quartz, potter's clay and turf. The manufactures consist of common stuffs, linen and cotton cloth, handkerchiefs, printed calicoes, flannels, stockings, porcelain, delf and earthenware, pipes, iron, cast metals, sugar baking, vinegar, liqueurs, mineral acids, lamp-black, leather, morocco, ropes, paper, glass, tanning, brass founding, cotton spinning, sugar refining, salt making, forging, blast furnaces, nail making, a royal foundry for cannon and ship building both for merchants and the state. The trade lies chiefly in grain, faggots, wool, cattle, wines, brandy, sugar, honey, building wood, iron, salt,

dry and salted fish, spices, drugs, colonial produce, exports and imports to and from the principal states of Europe, Africa and the Indies, fishing tackle for the cod fishery in Newfoundland and Cape Breton, and the herring, mackerel, and pilchard fishery. It also largely supplies the navy with provisions and ammunition. The principal rivers of the department are the Loire, the Sevre Nantaise, the Acheneau, the Boulogne, the Brive, the Don, the Isac, the Erdre, the Ognon, and the Tenu navigable; the Vilaine, the Logue, the Cher and the Maine: it is crossed by the great roads of Rochelle, Vannes, Rennes, and Angers.

LOIRET, THE, a department of France, consists of part of the former province of Orlennais, and takes its name from the little river Loiret, which rises here, and falls into the Loire below Orleans. This town is the chief place of the prefecture, which is divided into four arrondissements: Orleans, containing 133,006 inhabitants; Gien 38,550; Montargis 61,942; and Pithwiers 57,896; being a total population of 291,394 souls, on an extent of 2016 square miles; thirty-one cantons and 363 communes. This department yields a territorial revenue of 17,516,000 francs, is in the first military division, has a royal court and bishopric at Orleans, contains three electoral arrondissements, which send five members to the chamber of deputies. It is bounded on the north by the departments of Seine-et-Oise and Seine-et-Marne; on the east by that of the Gonne, on the south by those of the Cher and the Loir-et-Cher, and on the west by that of the Eure-et-Loir.

This is generally a level country, composed of fertile plains, vast forests, hills covered with vines, beautiful meadows and numerous pastures. That part, which extends along the right bank of the Loire from Orleans to Briare, and for a great distance inland, presents nothing but a sterile and sandy soil; the hills, however, are covered with vines, which yield excellent red and white wines. Great numbers of cattle also, and abundance of poultry, especially turkeys, are reared here for the supply of the capital. The climate is temperate and healthy; the soil, which is mostly fat and rich, is cultivated with horses and yields more than sufficient for its inhabitants; there are 95,700 hectares of forests, and 39,000 of vineyards, each hectare of arable land producing twenty-four francs twelve centimes. The productions of this department are all sorts of wheat, barley, buck-wheat, maize, millet, dry vegetables, hemp, flax, fine saffron, good fruits of every kind, pasturage for cattle, wood, abundance of game, river fish, numerous herds of cattle and flocks of sheep, poultry, and bees. There is a botanical garden at Orleans; mines of antimony and quarries of stone for building, marl and potter's earth. Mineral springs are found in different communes, and establishments of mineral waters at Segay and Beaugency.

Considerable manufactures are carried on by the inhabitants, in woollen counterpanes, cloth, serge, caps, paper, parchment, leather, files, shot, brass pots, pipes, and highly esteemed vinegar. They have likewise sugar-refining houses, brandy distilleries, wax-bleaching houses,

cotton and wool spinning mills, brass foundries and famous tan-yards. Their trade consists in faggots, corn, wine, vinegar, brandy, spices, drugs, fruits and fruit trees, vegetables, chestnuts, cyder, excellent honey, saffron, salt, wool, wood, charcoal, cattle, &c. The principal rivers of this department are the Loire and the Loiret, navigable; the canals of Briare and Orleans, the Loing, the Bied, the Ouanne, the Essonnes and the Cosson; and the chief roads are those of Paris, Malon, Bourges, and Tours.

LOIRET, THE, a small river, which rises from a very deep spring at the chateau de la Source, about a league below the bridge of Olivet, in the department to which it gives its name; and, after running a course of scarcely nine miles, falls into the Loire below St. Mesmin. It is navigable from the mills of la Chausse Inferieure to its mouth, and possesses the singular property of never being frozen over, however intense the cold. Many factories are established on its banks, and in time of frost it serves for a receptacle to the Orleans boats, which run up for shelter as far as St. Mesmin.

LOITER, *v. n.* } Belg. *leuteron*; Goth. *la-*
LOITERER, *n. s.* } *tur.* To delay; linger; idle time away.

Ever listless *loiterers*, that attend

No cause, no trust, no duty, and no friend.

Pope.

What folly can be ranker? like our shadows,
Our wishes lengthen as our sun declines,
No wish should *loiter*, then, this side the grave.

Young.

LOIZEROLLES (M. de) was a barrister at the time of the revolution, and was arrested, with his father, in 1793, on suspicion, and conveyed with him to the prison of St. Lazare. On the 7th of Thermidor, two days before the fall of Robespierre, the messengers of the revolutionary tribunal arrived at the prison with a list of the prisoners who were to be tried, and called for Loizerolles, the son. The young man was asleep, but the father, with a heroic wish to sacrifice his life for the preservation of his son, allowed himself to be taken to the Conciergerie, and appeared before the judges. The clerk, perceiving the error in point of age, substituted the name of Francis for John, the word father for son, and the age of sixty-one for twenty-two, and thus the father was led to the scaffold, though no charge or crime was alleged against him! M. Loizerolles, junior, has since celebrated this act of paternal affection in a poem, in three cantos, with historical notes (18mo., 1813).

LOKE, in mythology, a deity of the northern nations, answering to the Arimanius among the Persians, whom they represent as at enmity both with gods and men, and the author of all the evils which desolate the universe. Loke is described in the Edda as producing the great serpent which encircles the world; which seems to have been intended as an emblem of corruption or sin; he also gives birth to Hela or death, the queen of the infernal regions; and to the wolf Fenris, who is to encounter the gods and destroy the world.

LOKEREN, a large town of the kingdom of the Netherlands, in East Flanders, on the

Durme, a small river from which is a canal uniting it with the Scheldt. It carries on a good trade in corn, hemp, flax, and linen. The manufactures are woollens, lace, cotton, hats, and tobacco works: it has also fifteen oil mills. Population 12,800; twelve miles north-east of Ghent.

LOKMAN, surnamed the Wise, an eminent philosopher among the Easterns. The Arabians say he was the son of Baura, the son or grandson of a sister of Job. He was an Ethiopian, and a slave for some time. It is said that he was born in the time of David, and lived till the age of the prophet Jonas, a period of about 240 years. Some suppose him to have been the same with Æsop the mythologist: and indeed his Parables or Apologues in Arabic, as well as many particulars in his life, resemble the fables and fortune of Æsop. He is said, like Æsop, to have been deformed in his person, and some of his pieces are still extant; Mahomet entitled a chapter of the Koran after his name, in which he introduces God as saying, 'We heretofore bestowed wisdom on Lokman.' He obtained his liberty on account of his obedience in eating the whole of a bitter melon, at his master's command. His master, surprised, asked how it was possible for him to eat such a nauseous fruit? He answered, 'I have received so many favors from you, that it is no wonder I should once in my life eat a bitter melon from your hand.' M. Galland translated all the fables of Lokman, and Bidpai or Pilpay, a brahmin philosopher, which were published at Paris in 1724. Erpenius published his fables and grammar in Arabic and Latin, at Leyden, in 1636.

LOLIUM, darnel grass, in botany, a genus of the dignymia order, and triandria class of plants, natural order fourth, gramina: CAL. monophyllous, fixed, and uniliferous.

L. perenne, red darnel, or rye-grass, is very common in roads and dry pastures, and makes excellent hay upon dry, chalky, or sandy soils. It is advantageously cultivated along with clover, and springs earlier than other grasses; thereby supplying food for cattle at a time when it is most difficult to be obtained. Cows, horses, and sheep eat it; goats are not fond of it.

L. temulentum, or white darnel, grows spontaneously in ploughed fields. If the seeds of this species are malted with barley, the ale soon occasions drunkenness; mixed with bread corn, they produce but little effect unless the bread is eaten hot.

LOLL, *v. n. & v. a.* Belg. *luyegin*, *luy*, idle, and *ligen*, to lie; Belg. *lullen*; Teut. *loellen* is to suck with the tongue.—Thomson. To lie idle upon or against; recline lazily: to hang or put out the tongue.

So hangs, and *lolla*, and weeps upon me: so shakes and pulls me. *Shakespeare. Othello.*

He is not *lolling* on a lewd love bed,
But on his knees at meditation.

Id. Richard III.

Close by a softly murmuring stream,
Where lovers used to *loll* and dream.

Hudibras.

To *loll* on couches, rich with cytron steds,
And lay your guilty limbs in Tyrian beds.

Druden.

With harmless play amidst the bowls he passed,
And with his *lolling* tongue assayed the taste. *Id.*

By Strymon's freezing streams he sat alone,
Trees bent their heads to hear him sing his wrongs,
Fierce tygers couched around, and *loll'd* their fawn-
ing tongues. *Id. Virgil.*

A lazy, *lolling* sort
Of ever listless loiterers. *Dunciad.*

'Tis done—he steps into the welcome chaise,
Lolls at his ease behind four handsome bays,
That whirl away from business and debate
The disencumbered Atlas of the state. *Cowper.*

LOLLARD (Walter), founder of the sect of the Lollards, is said to have been an Englishman. He first introduced his doctrines in Germany, about A.D. 1315. After preaching with great zeal, and gaining many proselytes on the continent, he returned to England, where his disciples were called Lollards. He and his followers rejected the sacrifice of the mass, extreme unction, and penances for sin; insisting that Christ's sufferings were sufficient. He is likewise said to have set aside baptism as a thing of no effect; and repentance, as not absolutely necessary. But, in that age, none who had the courage to oppose the errors of the church of Rome escaped slander or persecution. Lollard sealed his testimony with his blood, being burnt alive in Cologne in 1322.

LOLLARDS, in ecclesiastical history, a religious sect, which arose in Germany about the beginning of the fourteenth century; so called from W. Lollard, their founder. See the last article. Some derive the name from *lolum*, a tare, as if the Lollards were tares in God's vineyard: others derive *lollhard*, *lullhard*, *lollert*, or *lullert*, from the old German word *lullen*, *lollen*, or *lallen*, 'to sing with a low voice;' and say, Lollard means a singer, or one who is continually praising God with a song. The Alexians or Cellites were called Lollards, because they were public singers who interred those who died of the plague, and sang a dirge in a mournful tone as they carried them to the grave. The name was afterwards assumed by persons who, though they made many pretences to piety, entertained the most ridiculous opinions, and committed the most enormous vices. And many injurious aspersions were propagated against those who assumed this name by the priests and monks; so that, by degrees, any person who covered heresies or crimes under the appearance of piety, was called a Lollard. Thus the name was formerly common to all persons and sects who were supposed to be guilty of impiety against God or the church, under profession of extraordinary piety. However, many societies of Lollards, of both sexes, were formed in most parts of Germany and Flanders, and were supported partly by their manual labors, and partly by charitable donations. The magistrates and inhabitants of the towns where they resided favored and protected them, on account of their usefulness to the sick. They were thus supported against their malignant rivals, and obtained many papal constitutions, by which their institute was confirmed, their persons exempted from the cognisance of the inquisitors, and subjected entirely to the jurisdiction of the bishops; but, as these measures

were insufficient to secure them from molestation, Charles, duke of Burgundy, in 1472, obtained a solemn bull from pope Sixtus IV., ordering that the Cellites or Lollards should be ranked among the religious orders, and delivered from the jurisdiction of the bishops; and pope Julius II. granted them yet greater privileges in 1506. In England, the followers of Wickliffe were called, by way of reproach, Lollards, from some affinity between their tenets. They were solemnly condemned by the archbishop of Canterbury and the council of Oxford.

LOMBARD (Lambert), an eminent painter, born at Liege in 1500; who, after a diligent study of the antique at Rome, introduced that style of painting among his countrymen instead of the Gothic. He painted historical and architectural pieces; and, though he could never altogether free himself from his national taste, he is ranked among the best painters of his time. He died in 1560.

LOMBARD (Peter), well known by the title of Master of the Sentences, was born at Novara in Lombardy; but, being educated in Paris, he distinguished himself so much at that university, that he was first appointed canon of Chartres; afterwards tutor to Philip, son of Louis VI., and lastly bishop of Paris. He died in 1064. His work on the Sentences is looked on as the source of the scholastic theology of the Latin church. He wrote also Commentaries on the Psalms, and on St. Paul's Epistles.

LOMBARDO-VENETIAN KINGDOM, a name given in 1815, at the congress of Vienna, to Austrian Italy, comprising both Lombardy and the former Venetian territory. See ITALY.

LOMBARDS, a nation of Scandinavia, who formerly settled in Italy, and for some time made a considerable figure. The name of Lombards, or Longobards, is derived by Paulus Diaconus, their historian, who was himself a Lombard, from the length of their beards. A nation, called Lombards, is mentioned by Tacitus, Strabo, and Ptolemy; but these are different from the Lombards who afterwards settled in Italy, and are reckoned to be the same with the Gepidæ, whom the Italian Lombards almost exterminated. The Lombards who settled in Italy are first mentioned by Prosper Aquitanus, bishop of Rhegium, in 379, who tells us, that about this time the Lombards, abandoning the most distant coasts of the ocean, and their native country Scandinavia, and seeking for new settlements, as they were overstocked with people at home, first attacked and overcame the Vandals in Germany. They were then headed by two chiefs, Iboreus and Aion; who, dying about A. D. 389, were succeeded by Agilmund.

The Lombards were at first a cruel and barbarous nation; but their native fierceness gradually wore off, after they had embraced the Christian religion; and they governed with such equity and moderation, that most other nations envied the happiness of those who lived under them. Under their government, says Paulus Diaconus, no violence was committed, no one unjustly dispossessed of his property, none oppressed with taxes; theft, robberies, murder, and adultery, were seldom heard of; every one

went, without apprehension, wherever he pleased. Their laws were so just and equitable, that they were retained in Italy, and observed there some ages after their kingdom was at an end. Their dress was loose, and for the most part of linen, such as the Anglo-Saxons wore, being interwoven with various colors; their shoes were open to the end of their foot, and they used to button or lace them. From some ancient paintings, it appears, that they shaved the back part of their heads, but that their hair was long before; their locks being parted, and laid on each side their foreheads.

Agilmund is commonly reckoned the first king of the Lombards. Before the time of Odoacer the history of the Lombards affords nothing remarkable; in his time, however, they settled on the Danube, in the country of the Rugians, whom Odoacer had either exterminated or carried into captivity. During their stay in this country they rendered themselves formidable to the neighbouring nations, and carried on successful wars with the Heruli and Gepidæ. In 526 they were allowed by the emperor Justinian to settle in Pannonia; and here they made war a second time with the Gepidæ. Alboinus, the Lombard king, killed the king of the Gepidæ with his own hand, put his army to the rout, and cut such numbers of them in pieces, that they ceased from that time to be a nation. Having caused the deceased king's head to be cut off, he made a cup of his skull, which he used in all public entertainments. However, having taken, among many other captives of great distinction, Rosamunda, the late king's daughter, he married her after the death of his former wife Clodisvinta, the daughter of Clotaire king of France. By this victory Alboinus gained such reputation, that his friendship was courted by Justinian; and, in consequence of the emperor's application, 6000 Lombards were sent to the assistance of Narses against the Goths. The success of the Romans in this expedition, the invasion of Italy by the Lombards, and their successes, have been related under ITALY. At last Alboinus having made himself master of Venetia, Liguria, Æmilia, Etruria, and Umbria, was murdered in the year 575, the fourth of his reign, by the treachery of his wife, whom he had irritated to the most implacable vengeance, by ordering her, one day, at a feast at Verona, to drink merrily with her father, presenting her with the cup above-mentioned. This she accomplished by the assistance of Helmi-child, the king's shield-bearer, who at first peremptorily refused to engage in the treason; but Rosamunda having, by placing herself in his mistress's bed, drawn him into an adulterous connexion with herself, told him he must now either kill Alboinus, or be himself put to death; promising at the same time to marry him, if he accomplished it, and bestow on him the kingdom. This last part of her promise, however, she did not get fulfilled, as they were obliged to save themselves by flight. They fled to Longinus the exarch of Ravenna, taking with them all the jewels and treasure of the late king. Longinus receiving her with the greatest kindness, assured her of his protection; and, judging this a favorable opportunity of making himself king of Italy, proposed to marry her, provided she dis-

patched Helmichild. Rosamund, pleased with the proposal, resolved to satisfy her ambition by getting rid of the man she had married to gratify her revenge. Accordingly, having prepared a strong poison, she mixed it with wine, and gave it to her husband as he came out of the bath; but he had not half emptied the cup, when, from its sudden effects, he concluded what it was, and compelled her to drink the rest. They both died in a few hours. Longinus, on her death, laid aside thoughts of making himself king of Italy, and sent the king's treasure to Constantinople, together with Albisoinde, the daughter of Alboinus by Rosamund, whom she had brought along with her. After the death of Alboinus the Lombards chose Clephis, one of the nobility, for their king. He was murdered after a short reign of eighteen months; upon which ensued an interregnum of ten years. During this time they extended their conquests in that country; but, at last, the Romans, jealous of their progress, resolved to put a stop to their victories, and, if possible, to drive them quite out. For this purpose they entered into an alliance with the Franks; which so alarmed the Lombards, that they re-established the monarchical form of government among themselves, and chose Autharis, the son of Clephis, for their king. This monarch, considering that the power of the dukes, who had governed Lombardy for ten years, was very much established, allowed them to continue in their government; but obliged them to contribute a moiety of their revenues towards the support of his royal dignity, and take an oath that, in the time of war, they would assist him to the utmost of their power. Having thus settled matters with the dukes, he enacted several wholesome laws against theft, rapine, murder, adultery, &c., and was the first Lombard king who embraced Christianity. Most of his subjects followed his example, but, being instructed by Arian bishops, disputes continued long between them and the orthodox bishops of the cities subject to them. From the re-establishment of the monarchy under Autharis, to the reign of Rotharis in 636, the history of the Lombards affords nothing memorable. This period is remarkable for the introduction of written laws among these people. Before this time they had been governed only by tradition; but Rotharis, in imitation of the Romans and Goths, undertook the publishing of written laws; and, to those which he enacted, many were added by succeeding princes. These laws were enacted in public assemblies, convened for that purpose, after they had been examined and approved of by all the lords of the kingdom; the legislative power being lodged in the king and nobles alone. Rotharis also carried on successful wars with the exarch of Ravenna, whom he totally defeated in several engagements, and made himself master of part of his territories. He died in 652; and the affairs of the Lombards went on prosperously, till the ambition of Luitprand laid the foundation of the total ruin of his kingdom. He ascended the throne in 711, and watched all opportunities of enlarging his dominions at the expense of the emperors. In 726, the emperor Leo III. having forbidden the worship of images, and ordered them to be pulled

down, the people revolted. And having strictly enjoined his officers in the west, especially the exarch of Ravenna, to see his edict punctually obeyed, Scholasticus, then exarch, began to pull down the images in Ravenna; which incensed the superstitious multitude to such a degree, that, taking arms, they openly declared they would rather renounce their allegiance to the emperor than the worship of images. Luitprand seized this opportunity of making himself master of the seat of the exarch; having drawn together all his forces, he unexpectedly appeared before Ravenna, and closely besieged it. But the exarch defended the place with such courage, that Luitprand broke up the siege, and led his army against Classis, which he took, plundered, and levelled with the ground. The severe treatment the inhabitants met with, threw the citizens of Ravenna into the utmost consternation; which Luitprand resolved to take advantage of, and, returning before Ravenna with his whole army, by frequent attacks tired the inhabitants and garrison to such a degree, that the exarch, despairing of relief, privately withdrew. Luitprand, having carried the town by storm, gave it up to be plundered by his soldiers, who found in it an immense booty, as it had been long the seat of the emperors, the Gothic kings, and the exarchs. The reduction of Ravenna was followed by the surrender of several cities of the exarchate, which Luitprand reduced to a dukedom; appointing Hildebrand, his grandson, to govern it with the title of duke, and, as he was yet an infant, appointing Peredeus, duke of Vicenza, for his guardian. The conquest of the greater part of the exarchate alarmed Gregory II. though he was then at variance with the emperor, whose edict against the worshipping of images he had opposed. But, jealous of the power of the Lombards, he exerted his influence with Urfus, doge of Venice, who resolved to assist the exarch with the whole force of the republic. The exarch accordingly laid siege to Ravenna by land, while they invested it almost at the same instant by sea. Peredeus defended the town for some time with great courage and resolution; but the Venetians, having forced open one of the gates, the city was taken, and Peredeus slain, while attempting to drive the enemy from the posts they had seized. Hildebrand fell into the hands of the Venetians; who, having thus recovered Ravenna to the emperor, returned home, leaving the exarch in possession of the city. Luitprand was then at Pavia; but the town was taken before he was able to assemble his troops for its relief. Gregory, persuading himself that the emperor would now, out of gratitude for the recovery of Ravenna, give ear to his admonitions, began to solicit him with the most pressing letters to revoke his edict against the worship of images: but Leo, instead of complying, sent three officers to Rome, with private orders either to assassinate the pope, or send him prisoner to Constantinople: and in 725 he recalled Scholasticus, and sent Paul, a patrician, into Italy, to govern in his room, with private instructions to encourage the above-mentioned officers. But, in the mean time, the plot was discovered, and two of the conspirators were

apprehended by the citizens of Rome, and put to death; the third having escaped. Hereupon the exarch drew together a considerable body of troops, and set out on his march to Rome, with a design to seize the pope, and send him in chains to Constantinople. But the politic Luitprand now leagued with Gregory against the exarch, in order to preserve the balance of power between them, and, by assisting sometimes the one and sometimes the other, weaken both. The consequence of this coalition was, that, the superstition of the people being awakened, almost the whole of Italy revolted from the emperor. Meantime the exarch Paul, having gained a considerable party in Ravenna, began to remove the images out of the churches. Hereupon the adverse party, encouraged by the pope, flew to arms; and, falling upon the Iconoclasts, gave rise to a civil war within the walls of Ravenna. Great numbers were killed on both sides; but, the worshippers of images prevailing, a dreadful slaughter was made of the opposite party, and the exarch himself was murdered. However, Ravenna continued faithful to the emperor; but most of the cities of Romagna, belonging to the exarchate, and all those of Pentapolis, abhorring the emperor as a heretic, submitted to Luitprand. In Naples, Exhilaratus, the duke, having received orders from Leo to execute his edict, endeavoured to persuade the people to receive it; but, finding all his endeavours thwarted by the pope, for whom the Neapolitans had a great veneration, he hired assassins to murder him. But, the plot being discovered, the Neapolitans murdered both the duke and his son, with one of his chief officers. They still, however, continued steadfast in their allegiance to Leo, who sent one Peter to govern them in the room of Exhilaratus. In the mean time Leo, not doubting but the pope was the chief author of so much mischief, sent the eunuch Eutychius into Italy, with the title and authority of exarch, strictly enjoining him to get the pope despatched, as his death was absolutely necessary for the tranquillity of Italy. But a messenger, whom the exarch had sent to Rome, being apprehended, and the emperor's order being found upon him, the pope's friends thenceforth guarded him with such care, that the exarch's assassins could never afterwards find an opportunity. The Romans were for putting the messenger to death; but the pope interposed, contenting himself with excommunicating the exarch. And now the Romans, provoked more than ever against Leo, resolved to revolt, and appoint their own magistrates, keeping themselves united under the pope, not yet as their prince, but only as their head. Eutychius, having brought with him from Constantinople a good number of troops, easily quelled the rebellion at Ravenna, and severely punished the authors. But he found he could never reduce them, so long as they were supported by the Lombards: and therefore he employed all his art and policy to take off Luitprand from the party of the Romans, and bring him over to his own. Luitprand, for some time, withstood all his offers; but Thrasimund, duke of Spoleto, revolting at this juncture, the exarch offered to assist the king against the rebellious

duke, provided he would assist him against the pope and the Romans. With this proposal Luitprand readily closed; and the two armies joined, and began their march towards Spoleto. At their approach, the duke, despairing of being able to resist two such powers, sued for pardon; which Luitprand not only granted, but confirmed him in the dukedom, after he had obliged him to take a new oath of allegiance, and give hostages for his future fidelity. From Spoleto the two armies marched to Rome; and encamped in the meadows of Nero, between the Tiber and the Vatican. Gregory had caused the city to be fortified; but, being sensible that the Romans alone could not long hold out against two such armies, he went to the king in his camp; and there, with a pathetic speech, softened Luitprand to such a degree, that, throwing himself at his feet in presence of the army, he begged pardon for entering into an alliance against him; went with him to the church of St. Peter, and laid his girdle, sword, gauntlet, royal mantle, crown of gold, and cross of silver, on the apostle's sepulchre. After this he reconciled the pope with the exarch, who was thereupon received into the city, where he continued for some time, in a friendly correspondence with the pope. At this time an impostor, taking the name of Tiberius, and pretending to be descended from the emperors, seduced many people in Tuscany, and was by them proclaimed emperor. Gregory, wishing to oblige Leo, persuaded the Romans to attend the exarch in his expedition against this usurper, whom they soon took in a castle, sent his head to the emperor, and suppressed the rebellion. But Leo, still insisting upon his edict against the images being received in Rome, the Romans, at the instigation of the pope, publicly renounced their allegiance, paid him no more tribute, and withdrew for ever their obedience to the eastern emperors. On this Leo caused all the patrimonies of the church in Sicily, Calabria, and his other dominions, to be confiscated; and raised a powerful army to recover the towns that had revolted. Gregory, alarmed at these warlike preparations, resolved to recur to the protection of the French, the only nation then capable of coping with the emperor, and on whom, on account of their zeal for religion, he thought he might depend. They were, at this time, governed by the celebrated Charles Martel, who was reckoned the greatest hero of his age. To him, therefore, Gregory sent a solemn embassy, with a great number of relics, earnestly entreating him to take the Romans, and the church, under his protection, and defend them against the attempts of Leo. The ambassadors were received with extraordinary marks of honor; and a treaty was soon concluded between them and Charles. But Gregory did not long enjoy the fruit of this negotiation; for he died the same year, 731, and was succeeded by Gregory III. The French nation, by the bravery and conduct of Charles Martel, had now become the most powerful kingdom in the west. His successor, Pepin, was no less wise and powerful than his father; and, as the ambition of the Lombard princes would be satisfied with nothing less than the entire conquest of Italy, the French monarch, Charlemagne,

under color of assisting the pope, at last put an end to the empire of Lombardy, as related under the article FRANCE.

LOMBARDY, a country of Upper Italy, is a name commonly given to the whole tract of country between the Alps and the Appennines, or between the frontiers of Switzerland and Tuscany. It is more strictly applicable to the vale of the Po only. In the more general acceptation it is about 250 miles in length, and 150 in breadth, and corresponds pretty nearly to the Gallia Cisalpina of the Romans. It derived its present name from the Lombards of the sixth century, who occupied it as a kingdom till the eighth. Lombardy is divided into Upper and Lower: the former, the western part, comprehending the Milanese, and a portion of the Sardinian territory; the latter, Parma, Modena, the papal legislation, and great part of the Austrian government of Venice. It is also divided into Cispadan, and Transpadan Lombardy: the former, or Lombardy on this side the Po, including all the territory between that river and the Appennines; Transpadan Lombardy, or Lombardy beyond the Po, all that is between that river and the Alps. The states of Lombardy at present are Austrian Italy, Sardinia, Parma, Modena, and Lucca.

LOMBLEM, one of the Sunda Islands, between the larger islands of Floris and Timor, and the eighth and ninth degrees of south latitude. It is itself about fifty miles in length, by sixteen average breadth; but has never been explored.

LOMBOCK, an island in the eastern seas, separated from that of Bally by the straits of Lombock, and from Sumbawa by the straits of Allas. It is about fifty-three miles in length, north and south, and forty-five in average breadth, very mountainous, but covered with wood and verdure. At the town of Bally, in the Straits of Allas, and in the many flourishing plantations and villages of the coast, European ships passing to the east are well supplied. The articles required in exchange are fire-arms, ammunition, or dollars. Its commerce with the neighbouring Malay Islands is also extensive. The inhabitants are supposed to have been originally emigrants from Hindostan, and retain most Hindoo customs.

LOMBOCK, THE STRAIT OF, is formed by the island of Bally west, and that of Lombock east. The south entrance is in long. $115^{\circ} 43' E.$, and in lat. $8^{\circ} 45' S.$, where is a large island, called Banditti Island, to the west of which there is no passage. The navigation is here extremely dangerous, owing to the great rapidity of the tides. The strait of Allas, formed by the island of Lombock to the westward, and that of Sumbawa eastward, is reckoned the best and safest to the eastward of Java, having generally anchorage at the towns and villages.

LOMOND HILLS, several verdant hills of Scotland, in the west part of Fifeshire, distinguished by different names. The two highest are called the Eastern and Western Lomonds. From their relative situation, more than from their magnitude, they command a very extensive and variegated prospect into many distant as well as adjacent counties, and are seen at a

very great distance by travellers in various directions.

LOMOND, EASTERN, the most regular and beautiful of the above hills, is said to be about 550 yards in height above the level of the plain; and, where it is most accessible, seems to have been fortified near the top with a deep trench. It lies a little west of Falkland, and is skirted with furze, above which it exhibits a beautiful verdure at all seasons, and rises into a conical summit. It slopes gradually on the east, but on the west the descent is steep, down to the gap or valley below; which separates it from the Western Lomond, and extends above a mile nearly on a level. Very near the top there is a small cavity about one foot and a half in diameter, which, by travellers, has been esteemed a volcanic crater. It abounds with limestone, and has also some strata of good coal, and a lead mine.

LOMOND, WESTERN, is considerably higher than the Eastern, and has a large cairn of loose stones at the top. From its summit, the southern aspect has little variety, but a gradual and uniform descent, till it joins the parishes of Leslie and Portmouak.

LOMOND, LOCH, a large lake of Scotland, in Dumbartonshire, which Mr. Pennant styles 'the most beautiful of the Caledonian lakes.' The view of it from Tarbat presents an extensive serpentine lake, winding amidst lofty hills on the north, barren, bleak, and rocky, which darken with their shade that contracted part of the water. About twenty-eight islands are dispersed over the lake, well wooded; of these some just peep above the surface, and are tufted with trees; others are so disposed as to form a magnificent vista. Opposite Luss, at a small distance from the shore, is a mountainous isle almost covered with wood, near half a mile long. The largest island is two miles long, and stocked with deer. The lake is thirty-six miles long; its greatest breadth is eight; its greatest depth 120 fathoms. Its surface has, for many years past, been observed gradually to increase, and invade the adjacent shore. And, from a passage in Camden's *Atlas Britannica*, it appears, that an island existing in his time, called Camstraddan, in which was a house and orchard, is now lost. Large trees are also often found in the mud near the shore, overwhelmed in former times by the increase of water, occasioned by vast quantities of stone and gravel brought down by the rivers, and by the falls of their banks.

LOMONOZOF, a celebrated Russian poet, the great reformer of his native tongue, was the son of a fishmonger at Kolmogori, and was born in 1711. His genius for poetry was first kindled by the perusal of the Song of Solomon, versified by Polotski. He soon after left his father, and took refuge in the Kaikonospaski monastery at Moscow; where he indulged his taste for letters, and studied the Greek and Latin languages. In this seminary he made such progress in literature as to be employed by the Imperial Academy of Sciences. In 1736 that society sent him to the university of Marburg in Hesse Cassel, where he studied universal grammar, rhetoric, and philosophy, under the celebrated Christian

Wolf. He continued at Marburg four years, during which time he applied himself to chemistry, which he afterwards pursued with still greater success under the famous Henckel at Freyberg in Saxony. In 1741 he returned into Russia, was chosen in 1742 adjunct to the imperial academy; and, in 1743, member of that society, and professor of chemistry. In 1760 he was appointed inspector of the seminary, then annexed to the academy, and in 1764 Catharine II. made him a counsellor of state. Lomonozof excelled in various kinds of composition; but his chief merit is derived from his poetical com-

positions, the finest of which are his odes. They are greatly admired for originality of invention, sublimity of sentiment, and energy of language. In this, and other species of composition, he enriched his native language with various kinds of metre, and is hence styled the Father of Russian Poetry. His principal works were printed in 3 vols. 8vo. He wrote *Annals of the Russian Sovereigns*; and *The Ancient History of Russia, from its Origin to the Death of Yaroslav I.* in 1054; a work of great merit, as it illustrates the most obscure period in the annals of Russia. He died 4th of April, 1764.

L O N D O N.

LONDON, (Lat. Londin^{um} and Augusta), from the British Lyn-den, signifying the town on the lake, thus supplies in its name one of the earliest and most prominent facts of its history, i.e. that at the period of its foundation the Thames in this neighbourhood was rather a lake, occasionally subsiding into a stream, than a river regularly confined by fences and embankments. The name of the village of Mort-lake still perpetuates the same idea.

PART I.

EARLY HISTORY OF LONDON.

Ammianus Marcellinus mentions Londinium as the capital of the Trinobantes: and Tacitus says, 'London is so called from its situation, and Augusta from its grandeur.' If we advert to more remote writers, the chronicler, Geoffry of Monmouth, tells us that London was founded in the year 1108 before the Christian era, by Brute, a lineal descendant of Eneas, and called by him, after the great scene of his ancestor's exploits, Troy Novant, or New Troy, whence the inhabitants received the name of Trinovantes, or Trinobantes; and so, as we are further told, it continued to be called for 1000 years and more, till the sceptre having devolved on king Lud, a native of Britain, he gave it the name of Caer Lud, or Ludstoun, which in process of time became softened into London. Mr. Pennant, rejecting this story, has framed another of his own, nearly as fanciful. 'London,' he says, 'certainly existed prior to the invasion of Cæsar; it was, at the time of his arrival in this island, the capital of the Trinobantes, who had recently come from Belgium, and composed one of the small nations into which Britain was formerly divided. The name of this nation, as we learn from Baxter's British Glossary, was derived from the three following British words—tri now hant, which signify the inhabitants of the New City, the ancient name of the renowned metropolis of Britain.'

But the Commentaries of Cæsar at once dissipate these visions of the early grandeur of our metropolis, and prove that it owed every thing worthy of that character to the Romans. He tells us that 'what the Britons called a town was nothing more than a thick wood, surrounded by a ditch and fortified by a rampart, into which they retired when apprehensive of invasion.'

The proofs are indubitable, that the Britons knew nothing of brick-making at this period, and had never, so far as the Romans could observe, attempted to raise one stone above another. No traces of building have ever yet been discovered about London, which could with any probability be ascribed to a period anterior to the Roman invasion; though, of the natural advantages of the place, the Britons were probably as good judges as their conquerors. We find, accordingly, that as far as regards the site of London, a stronger one for purposes of defence could scarcely have been chosen. The heart of the city was on the summit of an angle of rising ground (about where St. Paul's cathedral now stands), bounded on the one side by the marshy Thames, on the other by the Fleta, a stream or torrent since covered over, which emptied itself into the Thames, near where Blackfriars-bridge has been since erected; and behind this naturally entrenched mount there was a thick wood, which extended far into the interior. We have only in imagination to cover this mount also with 'thick wood,' to complete the idea which Cæsar presents to us of the British town. So slowly, indeed, was the wood cleared away, that so late as the reign of Henry II. all the northern parts of the city bordered on a thick forest, where beasts of the chase roamed. When, under Cæsar, the Romans advanced to the Thames, the Trinobantes were the first of the tribes beyond that river who sent proposals of submission; and there is every reason to believe, that they formed no part of that native force which, under Cassivelaunus, attempted to oppose his progress. When victory declared for Cæsar, and he had effected the passage of the river, he found not only a friendly people in the Trinobantes, but, in their city or strong hold in the wood, as advantageous a position for encampment as the invader of an unknown territory could desire. It was such as a very slight application of the Roman skill in fortification could render impregnable to any attacks from the hostile nations of the interior; while, on the side of the Thames, he secured a free communication with the sea.

It has been a matter of dispute among antiquaries to determine the precise spot where Julius Cæsar forded the Thames. Camden and others think that it was at Shepperton, and that

what are called *Cowey Stakes* were planted there to obstruct his passage. Maitland, conceiving however that this would place the ford at a greater distance from London than would agree with Cæsar's account, was at great pains to discover a ford lower down. 'I endeavoured,' he says, 'by sounding the river at several neap tides, from Wandsworth to London-bridge, to discover a ford, which, to my no small satisfaction, I did, on the 18th of September, anno 1732, about ninety feet west of the south-west angle of Chelsea College-garden; where, in a right line from north-east to south-west, I found the deepest part of the channel to be only four feet seven inches deep.' But the state of any part of the river in modern times can be no evidence of what its state was in the time of the Romans. It is besides certain, that to the west of London-bridge, and not so high up as Chelsea, there existed, previous to the general embankment of the river, at least two well known fords. Milford Lane, opposite to St. Clement's Church in the Strand, was so called from a corn mill which anciently stood there, and from its leading to a ford across the river. At York House, the palace of the archbishop of York, which stood on the site of the streets adjoining to what still bears the name of York-stairs, there was another ford, which, as late as the beginning of the eighteenth century, had been used within the memory of many persons.

Mr. Bagford, another learned antiquary, in a letter to Hearne, written in 1714, says, 'And now I shall relate to you the manner of the Roman approaches near to London. These led along Kent Street, on the left hand, leading to London, and pointed directly to Dowgate, now so called, through an arch since built by the bishop of Winchester at his stairs, which, to this day, is called Stone Street, and came directly out of Surrey. It was at this very place (as I take it) that the Roman legions forded over the river of Thames, first the horse and then the foot, which might not then take them up to the shoulders. And this they might attempt (as we may conjecture) when the tide was first coming in, they then making an angle, and directing their course against the stream of the river. When they came to the middle of the stream, the tide drove them to their intended landing-place—which was Dowgate.'

At whatever place the Romans forded the river, it seems certain, at least, that the passage was not effected at any part lower than the junction of the Fleet with the Thames. All the territory within the angle formed by these two streams was occupied by the Trinobantes, who were in negotiation for a friendly treaty with the invader; and it must have been above it, therefore, that Cæsar found the hostile forces of Cassivelaunus drawn up to oppose his passage. It may possibly have been as far up as Cowey Stakes, but not less possibly as low down as the Millford;—in short, the range of reasonable conjecture is so wide, that nothing can be vainer than to attempt to come to a fixed conclusion on the subject.

1. *London, under the Romans.*—The Romans conquered to civilise. They showed the Britons

how to fashion the clay of their soil into bricks and domestic utensils; to build houses for themselves, temples to their gods, and courts for the administration of justice; to drain and embank; to cut roads and erect causeways; to lay out their towns in streets and squares, and to surround them with walls and towers. The Britons chose the site of London, but to the Romans we must allow the praise of adorning it with its earliest monuments of art.

It was soon perceived, by this sagacious people, that London, though well fitted by its natural strength for a military station, was still better qualified to be a place of extensive commerce. Seated at a considerable distance from the sea on a broad and navigable river, which, after watering some of the fairest portions of the island, discharges itself into the ocean almost in sight of the continent of Europe, it seemed calculated to be at once the mart for a great domestic and great foreign trade. The Romans, however, were warriors, and not traffickers; and they contented themselves with directing the Britons to the cultivation of those advantages, which have raised their capital to the proud pre-eminence which it now holds among the cities of the earth. We find, accordingly, that London was never, like other settlements of the Romans, formed into what they termed a military colony, exclusively Roman. Here the Roman prefects resided; and from this point, as we learn from the Itinerary of Antoninus, branched most of the great roads into the interior; both decisive proofs that they regarded it as the most important station they possessed in the island: yet neither did they occupy it alone, nor did they subject it to the inconvenient restrictions of a garrison-town. London remained a free city, where Roman and Briton mingled amicably together; and to which strangers from all parts were encouraged to resort with their commodities. So rapid was now the progress of London in commercial importance, that, as early as the revolt of the celebrated Boadicea, it is described by Tacitus as having become famous for the vast number of merchants who resorted to it, and the abundance of every species of commodity which it could supply. The first interruption to its prosperity arose from the early triumphs of this illustrious heroine. The Roman general Suetonius, unable in the outset to encounter so formidable a rebellion, was obliged to abandon London to its fate. Boadicea and her troops, eager to punish the ancient defection of the Trinobantes from the common cause of the native powers, and irritated by the spectacle which London presented of Roman greatness, massacred every soul they found in the city, and, setting fire to it in several places, nearly reduced the whole to ashes.

The Romans, however, again recovering the ascendancy, a new city speedily arose on the same favored spot, devoted as before to the peaceful pursuits of commerce, and flourishing by them. In the year 359 no less than 800 vessels are said to have been employed in the exportation from London of corn alone. On the decline of the empire, in the fifth century, London had to lament the departure of the be-

neficent founders of her greatness. There are various statements of the period when the Romans abandoned Britain; all that is certain is, that it took place not later than the year 450, when a dominion which brought many blessings to this island had wholly and for ever ceased.

2. *Roman remains.*—When the Romans evacuated London, they left it encompassed with lofty and well fortified walls. The circuit of them, as described by Stowe, measured two miles and a furlong; and this did not include the side towards the Thames, which, though originally walled in, was subsequently left to its natural defence: when perfect, the walls are supposed to have been twenty-two feet high. They commenced on the east with a large fort, erected on the present site of the Tower (supposed by Bagford still to survive under the name of the White Tower), and taking a semicircular direction by the Minories, Houndsditch, Cripplegate, Aldersgate, Newgate, and Ludgate, terminated in another lofty fort on the Thames, close to Fleet Brook. Besides these two principal forts, the walls were guarded by thirteen other towers, erected at proper distances on the land side, and supposed by Maitland, from some remains of them existing in his time, to have been about forty feet high. The entrances into the city on the land side were originally but three; by Aldgate on the east; Aldersgate on the north, and Ludgate on the west; but in the course of time many new gates were opened to facilitate communication with the country, such as Newgate, Cripplegate, Moorgate, Bishopsgate, the postern on Tower Hill, &c. The barbican, specula, or watch-tower, belonging to every fortified place, stood a little without the walls to the east of Aldersgate, on the spot which still goes by the name of Barbican. Mr. Bagford's account of the uses to which this was applied is curious. 'Here,' he says, 'the Romans kept cohorts of soldiers in continual service to watch in the night, that if any sudden fire should happen they might be in readiness to extinguish it, as also to give notice if an enemy were gathering or marching towards the city to surprise them. In short, it was a watch-tower by day, and at night they lighted some combustible matter on the top thereof, to give directions to the weary traveller repairing to the city, either with provision, or upon some other occasion. The same was intended by a lantern on the top of Bow steeple before the fire of London (although seldom made use of), for burning of lights, to give direction to the travellers and to the market people, that came from the northern parts of London. Of all these extensive out-works, walls, towers, and gates, very few vestiges remain.

The dangers which they were erected to avert, having long since ceased to exist: they have one after another been swept away in the course of modern improvement; and it is only by the names which survive, that their sites are now to be traced. The coins found at their foundations have been invariably Roman; an incontestable proof that it was to the protecting and magnificent spirit of the Roman people, that the British were indebted for the fortification of their capital. Some of the gates were very handsome and

costly structures; especially in later times, when the citizens delighted to distinguish themselves by benefactions and bequests for the embellishment of these inlets to their cherished city. Ludgate, which was taken down and rebuilt in the reign of queen Elizabeth, was not even at that time erected at a less expense than £1500; and the expenditure on the other gates was equally munificent. When in the last stage of their dilapidation they were ordered to be pulled down, they brought, even as old materials, considerable prices. Aldgate was sold for £157 10s.; Ludgate for £148; and Cripplegate for £91.

London Stone, now to be seen in the south wall of St. Swithin's Church, Cannon Street, was another monument of the Roman power. It appears to have been a miliary, of the same kind as that in the forum at Rome, where all the high-ways of the country met in a point, and from which they were measured. We have before alluded to the proof which this furnishes, that London was regarded by the Romans as the chief seat of their British dominion. When Jack Cade struck this stone with his sword, exclaiming, 'Now is Mortimer lord of London,' he was probably not unaware of its emblematic character.

According to Bagford, the Romans had in London a field of Mars, in imitation of that at Rome; and through so long a lapse of ages did the same spot continue to be appropriated to military exercises, that this field was no other than what, in more recent times, was called the Old Artillery Ground. 'On the farther side of Whitechapel Street,' he says, 'next Bishopsgate Street, was another station of the Romans, in that part which formerly bore the name of the Old Artillery Ground, and was their field of Mars, in which place the Romans trained up and exercised their young soldiers, and likewise the youth of the neighbouring Britons, in the skill and exercise of arms, that they might be more expert in the use of them upon all emergent occasions. And, if any sudden tumults or insurrections should happen in the city, they were then ready and at hand to suppress them. This field of Mars was in imitation of that at Old Rome, where they mustered their soldiers, and which must needs have been a very large place, as the same is excellently described and likewise observed to have been a Roman camp, by a judicious author in the latter end of queen Elizabeth's reign.

Of the temples of the Romans no specimens are now extant. In Norden's Middlesex, it is said, there was one near the Tilt Yard; and Bagford makes no doubt of there having been a temple of Diana on the south side of St. Paul's. The ruins of a building, called the Camera Dianæ, situated on the eminence of St. Paul's Wharf, existed in the time of How, who wrote a continuation of Stowe; and the tenements which have been since erected on its site are still designated in the leases of them as part and parcel of the ancient Camera Dianæ. From the accounts given of this structure, however, it does not appear to have been at all of the nature of a temple. The Camera Dianæ was a vaulted labyrinth, similar in its ground plan to the celebrated

Rosamond's Bower at Woodstock, and was employed by Henry II., of amorous memory, for the same purpose. The one was the country, and the other the town repository of this jewel of his heart. 'At this time,' says How, 'some ruins of it are remaining, and many evident testimonies of intricate turnings and windings, as also a subterraneous passage to Castle Baynard, which no doubt the king made use of privately to have access to his brightest Diana, one of the most exquisite and most celebrated beauties that we find mentioned in any history.' The name Camera Diane had an obvious reference to those purposes of chaste seclusion, for which the building was designed; and it would be preferring a less probability to a greater, to suppose that it derived this appellation from having been erected on the same spot where a Roman temple of Diana previously stood.

In December, 1803, a large and very beautiful specimen of Roman mosaic was accidentally discovered by some workmen employed in digging for a sewer immediately opposite the East India House. It is preserved in the honorable company's museum, and suggests to us a splendid idea of the extent to which the Romans had carried the internal embellishment of their houses. It is about eleven feet square, and exhibits the centre of the floor of an apartment, which could not have been less than twenty-two feet square, but in all probability was considerably larger. The figure of the god Bacchus is represented reclining on the back of a tiger. The drawing, coloring, and shadows, are all effected with great skill and ingenuity, by the use of about twenty separate tints, composed of tessellæ, of different materials. The major part consist of baked earthen, but the more brilliant colors of green and purple, which form the drapery, are of glass. These tessellæ are of different sizes and figures, adapted to the situations they occupy in the design; and are placed in rows, either straight or curved, as occasion demanded, each tessella presenting to those around it a flat side. The interstices of mortar being thus very narrow, and the bearing of the pieces against each other uniform, the work in general possessed much strength, and was, very probably, when uninjured by damp, nearly as firm as the solid stone. A mosaic pavement, with a similar device, was discovered in 1711—12 at Woodstock in Oxfordshire.

3. *London to the Danish conquest.*—The departure of the Romans proved the commencement of a long train of calamities to London. The sun of her prosperity seemed to have set. The Saxons, invited over to furnish that protection against the incursions of the Scots and Picts which the Romans could no longer afford, violated the compact which gave them a footing in the country; and during the vain and sanguinary struggles of the British, for nearly a century and a half, to preserve themselves from Saxon subjugation, London, from its importance, became, more than any other part of the island, a prey to the evils of intestine war. When the Saxons had at last established themselves in the sovereignty of the country, it was no longer with London that the metropolitan sceptre was suffered to re-

main. Ethelbert, king of Kent, to whom all the Saxon nations, south of the Humber, were feudatory, made Canterbury the seat of his government; and neglected London ceases to figure in history, except for the disasters which befel it. In 664 it was ravaged by the plague; in 764 it was wasted by fire; in 798 it again suffered severely from fire, and numbers of the inhabitant perished in the flames; and in 801, before there was time to repair the ruin done, a third conflagration nearly completed the work of destruction. On the establishment of the Heptarchy under Egbert, A. D. 827, the fortunes of London brightened for a moment. Egbert chose it for his residence, and here, in 833, a wittenagemot, or parliament, was held. But on the invasion of England by the Danes, soon after, they drove Egbert from his adopted capital, and, after delivering it up to pillage and massacre, reduced nearly the whole to ashes.

In such a succession of calamities, it was inevitable, that nearly all that beauty and magnificence which the Romans had imparted to London should for ever disappear. Its naked walls, in fact, alone remained; and if a city, far transcending even the Roman Augusta, has since arisen within and around them, it is to the British themselves that the merit and the fame belong.

After a dismal lapse of nearly four centuries, the reign of the renowned Alfred brought, among many blessings, the restoration of London to its former greatness and prosperity. Having, A. D. 884, freed the kingdom from the Danish yoke, he gave directions for rebuilding the desolated cities; and of these none claimed or received a larger share of his beneficent patronage than London. He repaired and strengthened the walls; he prevailed on the inhabitants, whose houses had hitherto consisted almost wholly of wood—the cause of repeated conflagrations, to rebuild many of them of brick and stone; he presented them with models of merchant ships, that would both sail better and carry larger cargoes than those of former times; and he laid down the plan of that excellent system of municipal government which, with various modifications and improvements, subsists to the present day. With such aids and encouragements, the renovation of London proceeded so rapidly, and the spirit of its citizens so much revived, that notwithstanding an accidental fire in 893, which occasioned very considerable injury, it was in a few years in a condition, for the first time since the departure of the Romans, not only to defend itself against invasion, but to go forth and meet the invaders. In 895 when a predatory party of the Danes, under the command of Hastings, encouraged by the absence of Alfred from his capital, had advanced as far as Beauflete, the garrison of London, joined by a body of gallant citizens who eagerly volunteered their services, went out and surprised the enemy in their camp, cut all who opposed them to pieces, took a great many prisoners, and spoiled the spoilers. When again, in 896, another body of the Danes had sailed up the river Lea to Ware, and posted themselves in a strong position between that place and Hertford, Alfred, at the head of his grateful and in-

crepid citizens, marched from London, attacked the enemy in their intrenchments, and compelled them to fly at all points.

In 994, about one century after the restoration of London by Alfred, during all which time it continued to increase in strength and opulence, the kings of Denmark and Norway, at the head of a numerous fleet and army, sailed up the Thames, with the hope of reducing the city to their power. The reins of the Saxon government were at this moment in the hands of the feeble and dastardly Ethelred II., and the citizens of London were left unassisted to the defence of their own walls. So bravely, however, did they defend them, that the enemy were repeatedly repulsed with great loss, and finally obliged to raise the siege. The Danes, though unable to make themselves masters of London, ceased not to harass every other part of the country with their incursions; till, weary of resistance, Ethelred abdicated his throne, and retired into Normandy, A. D. 1013. London, thus abandoned, was at length compelled to open her gates, and with her the whole of England submitted to the sceptre of Sweyn, king of Denmark.

On the accession of Canute, the son of Sweyn, to the throne, the citizens of London joined in the general effort made by the Saxons under the brave Edmund Ironside, the son of Ethelred, to throw off the Danish yoke. For a time the enterprise gave promise of a glorious triumph. Canute was obliged to abandon the capital to his rival; and, in 1016, Edmund Ironside was in London crowned king of England. Three times in the course of that year Canute returned and laid siege to it, but was as often repulsed with great loss. The contending princes, finding at length that their forces were too equally balanced, to give either a hope of sole dominion, entered into an agreement for a division of territory; but scarcely had this compromise been made, when the assassination of the gallant Edmund, by his perfidious relation Edric Streon, depriving the Saxons of a leader, left Canute sovereign of all England.

4. *London under the Danes and Normans.*—Historians have represented Canute as filled with resentment against London, for the strenuous resistance which it made to his pretensions, and its persevering attachment to the Saxon line. Of a tax of £82,000 Saxon, which he imposed on the whole country, the portion for which he assessed London was nearly one-eighth; and it is to this we are referred as a proof of the weight with which his vengeance fell upon this devoted city. It seems to us a great deal more probable, that one-eighth was only the fair proportion which the wealth of London then bore to that of the rest of the kingdom; for as yet agriculture had made but small progress in the inland counties; there were few or no manufactures; the bowels of the earth had scarcely begun to pour forth their mineral treasures; and whatever profit could be derived from commerce with foreign nations was almost wholly absorbed by the merchants of the Thames. Canute was too high minded to cherish an ungenerous recollection; too wise, had it been otherwise, to

satisfy his revenge by the oppression of a people whom he wished to attach to his dominion. He proved, in fact, a beneficent conqueror. He established order and tranquillity throughout the country; and was, perhaps, the first of our princes who was at the pains to protect his subjects in their commercial intercourse with foreign states, by treaties which had this alone for their object. A letter which William of Malmesbury has preserved (l. ii. c. 11), written by Canute to his regent in England, when he was on a pilgrimage to Rome, shows a solicitude on this head which does immortal honor to his memory. 'I have conversed,' he says, 'with the pope, the emperor, and all the princes whom I found here, respecting the grievances imposed on my subjects, whether English or Danes, on visiting their several states; and have insisted that in future they shall be treated more favorably, and exempted from the tolls and exactions of various kinds, with which they have been hitherto harassed. The emperor, king Rodolphus, and the other sovereigns, have accordingly listened to my remonstrances, and have assured me that henceforth no subject of mine, whether merchant or pilgrim, passing through their territories, shall meet with any obstruction, or be made liable to the payment of any impost whatever.'

On the death of Hardicanute, the third and last prince of the Danish line, the nation called to the throne a prince of the race of Alfred, in the person of Edward the Confessor. The privileges of London, which seem to have rested hitherto altogether upon usage and tradition, received from Edward their first statutory recognition; but what these privileges were does not distinctly appear. In the *Speculum*, one of the oldest records 'de antiquis legibus, libertatibus, et consuetudinibus civit. Lond.', there is a great deal of romance about the privileges of London being 'after the manner of old great Troy.' The only certain fact we are able to collect from it is, that London possessed from time immemorial a right of conferring liberty on such slaves or vassals as should reside for a year and a day within the city unclaimed by their lords; and that this was among the rights confirmed in general terms by Edward. The city was from this circumstance called the Free Chamber of the King of England; inasmuch as a slave so emancipated might ever afterwards 'as freely and securely tarry there, as if he were in the house or chamber of the king.' The value of such a privilege, at a time when the feudal system held all the rest of the kingdom in slavery, is beyond all calculation. It presented to the people at large the first chance of obtaining liberty through some other means than the benevolent caprices of their feudatory lords; it made London, to the rest of England, nearly what England has since become to all the world beside—the only spot, to touch which is to be free. Proud is the distinction which London thus enjoys, of having been the nursery of British liberty! A distinction only equalled by another, to which London has no less a claim, that of being for ages the chief strong hold of that liberty which she nursed and reared. So justly have the citizens appreciated a blessing, which, for

a long time they almost exclusively enjoyed, that there are instances upon record of individuals having been degraded from the rank of citizens, solely because, forgetting the freedom to which they had been raised, they had descended to hold in villainage lands without the limits of the city.

It was not by force of arms only, but by treaty and compact, that William the Norman advanced to the throne of England. The citizens of London, like the men of Kent, agreed to receive him for their king; but it was with arms in their hands, and with spirit to use them if they had been so inclined. That the Normans should abuse the influence which they acquired, by the elevation of their chief to the throne of England, was an event which might have been reasonably anticipated; but let us not confound want of prudence with want of courage.

The conditions on which the citizens of London consented to William's assumption of the crown formed the subject of a written charter, the first they ever possessed. It is still preserved among the city archives, and consists of only four lines, on a bit of parchment six inches long and one broad. The following is a literal translation of this interesting document:—'William the king greeteth William the bishop and Godfrey the portreve, and all the burgesses within London, friendly. And I acquaint you, that I will that ye be all there law-worthy, as ye were in king Edward's days. And I will that every child be his father's heir, after his father's days. And I will not suffer that any man do you wrong. God preserve you.'

To be law-worthy appears to have meant, that they should, in all cases of disputed right, or alleged crime, be entitled to a legal trial; that they should not, like men who still remained in a state of vassalage, be liable, in their persons or possessions, to arbitrary rule. That 'every child should be his father's heir,' insured the descent of property to the heirs of those who acquired it; an important privilege, for there were still numbers who held their lands and goods at the will of the feudal lords, and could never be sure of leaving any part of the fruits of their industry to their posterity.

Among the laws or customs of King Edward's days, referred to in this charter, we see that most important one of conferring freedom on every vassal or slave who could accomplish a residence of a year and day within the city, unclaimed by his lord. William not only confirmed this privilege to the city of London, but he extended it to all other cities and walled towns throughout the kingdom.

The first circumstantial detail of the rights of the city of London was contained in a charter of confirmation, granted by William's son, Henry I. Some of these have in the course of time been considerably modified; such as the exemption of the citizens from going (from being obliged to go), to war (*nullus eorum faciat bellum*); their freedom from all tolls, duties, and customs, throughout the realm; and the privilege of hunting in Chiltre, Middlesex, and Surry, now annually compounded for by a day's frolic at Epping. Others again have been lost entirely; particularly a right of summary execu-

tion against the goods of debtors without the walls: but the citizens have still, as is declared in this charter, the right of electing their own sheriffs and magistrates, and of being amenable only to courts held within the walls—for that rule, which is to this day observed by the king's courts of holding sittings in each term at Guild hall for the city of London, is but the practical result of this privilege; and they are still exempted from having soldiers, or any of the 'king's livery,' quartered upon them. A stout sheriff of the city, named John de Causton, once resisted, by force of arms, an attempt to invade this last privilege within the verge of the tower in the time of Edward II.; and, on being prosecuted for this contempt, as it was called, on the king's authority, was brought in 'faulty in nothing.'

It is deserving of remark, that this declaratory charter makes no mention of the rights of inheritance and of conferring freedom, recognised by the charter of William I.; and the omission can only be explained by the supposition, that they had by this time become matters of such notoriety and necessity, as not to be reckoned among those rights which stood in need of confirmation. The omission was not, however, without its consequences; for it gave occasion in the reign of Henry VI. to a writ of *inspeximus*, issued for the express purpose of ascertaining on what ground the city of London claimed the privilege of emancipating servants and natives, 'tarrying there for a year and a day.' The return which the lord mayor and aldermen made to this writ showed, so satisfactorily, that both London and all other walled cities and towns now possessed this right, that it was again solemnly recognized and confirmed by the king.

In the same charter by which he declared and confirmed the privileges of the citizens of London, Henry conferred on them, for an annual rent of £300, to be paid to his majesty and his heirs for ever, the perpetual sheriffalty of Middlesex. Considering the low prices of provisions at this period, it would seem that they paid dearly for the acquisition. For such was the prosperous state of the country during this reign that corn sufficient for a day's consumption of 100 persons, could be purchased for the small sum of 1s.; and a pint of wine was sold at the tavern for 1d., with bread for nothing! The prices of these articles have since increased at least forty-fold, so that the £300, paid by the city of London in the time of Henry I. for the privilege of giving sheriffs to the county of Middlesex, were equal to not less than £12,000 at the present day. The privilege was by no means, however, a nominal one though extravagantly paid for. The internal government of so large and increasing a metropolis as London could never have been well administered without it. Already had it suffered severely from the ease with which offenders could escape from the jurisdiction of its magistracy into the adjoining county of Middlesex; and was to remedy this grievance, that the citizens were now content to pay the price of a principality, to unite the powers of the sheriffalties of London and Middlesex in two freemen of their own nomination.

The reign of Richard I., though not one of glory or prosperity to England, cannot be said to have been productive of much positive harm. He scattered charters among his subjects, in order to raise the means of pursuing his schemes of adventure in foreign lands; but they were charters of liberty. He left his people in a great measure to shift for themselves; but the evil consequences of interfering little with the pursuits of an industrious nation, do not appear to have been enormous. When the chivalrous knight-errantry of Richard had terminated in an Austrian dungeon, London was both able and generously forward to contribute largely to his ransom; and on his return from captivity, such was the civic magnificence with which he was received in his ancient capital, that a German nobleman, who attended Richard to England, was constrained to observe, that 'had his master, the emperor, been aware of the wealth of the king of England's subjects, he would have demanded a far higher sum for his release.'

Richard was not unmindful of the loyal services which London rendered on this occasion. He granted the citizens a confirmation of all their rights and privileges, such as they existed in 'the freest and best' periods of their history, and he farther conferred upon them the conservatorship of the Thames, and the power of fixing a standard of weights and measures for the whole.

5. *Foundation of Westminster, and its junction with London.*—For several centuries after the foundation of London, the space which is now covered by the sister city of Westminster consisted of a small island, called Thorny, in consequence, says Stowe, of its being 'a place overgrown with thorns, and environed with waters.' Here, according to monkish chronicles, there anciently stood a heathen temple of Apollo, out of the ruins of which Sebert, king of the East Saxons, after his conversion to Christianity A.D. 612, erected a church, which he dedicated to St. Peter, and which forms the east angle of what is now called Westminster Abbey. Sir Christopher Wren, however, could not discover in the materials of this structure the least trace of heathen or Roman art. The church of St. Peter's was certainly one of the earliest architectural monuments of the introduction of Christianity into Britain; but it was, in all probability, not erected till after the principal remains of the Roman power had been swept away amidst the furious struggles, which ended in the subversion of Britain to the Saxons.

When the Danes began, in their turn, to contend for mastery with the Saxons, the church of St. Peter's suffered severely from their devastations; and but for the piety of Edgar the Peaceable, who repaired it in 958, and, at the same time, erected it into a monastic establishment, it might not have survived the downfall of a Saxon dynasty. From its situation to the westward of London, it was now called (in monkish Latin) *Westmonasterium*, and hence the modern name of Westminster.

On the temporary restoration of the Saxon dynasty, in the person of Edward the Confessor, Westminster was one of the few places to which that event proved auspicious. By the peniten-

tiary labors of this sceptred monk the abbey was enlarged into that magnificent fabric which, embellished by Sir Christopher Wren, now stands the admiration of the world; and near to it he erected a palace (on the site since called Old Palace Yard) which, though now no more, made Westminster the seat of royalty, as well as of ecclesiastical splendor. The courts of law and parliament necessarily attached themselves to the spot where our kings resided; and contributed, in a very material degree, to raise Westminster to dignity and importance.

In 1257 Henry III. granted to the abbot and convent of Westminster the privilege of holding a market and fair, for the space of forty days; and in 1352 the town had so much increased, that Westminster was one of the ten places where, by act of parliament, the staple of wool was to be perpetually held.

An order of council was passed in the ensuing year (1353), which imposed a duty on every pack of wool, as well as all other goods, 'carried either by land or water to the staple of Westminster;' 'for the purpose of repairing the highway leading from the gate of London, called Temple Bar, to the gate of the Abbey at Westminster.' It is evident, from this record, that London and Westminster were then regarded as distinct towns; but it would be, perhaps, too much to infer, that 'the highway' between them, 'now the noble street, called the Strand, was not then built upon, but was a mere country road, having, however, many noblemen's and gentlemen's houses and gardens adjoining to it,' &c.; Hughson, vol. i. p. 78. For we learn, from the same order of council, that the cause of the impost was, the 'highway being, by the frequent passing of carts and horses, carrying merchandise and provisions to the said staple, become so deep and miry, and the pavement so broken and worn, as to be very dangerous both to men and carriages;' and we farther find, that it was ordained, that 'all owners of houses, adjacent to the highway, should repair as much as lay before their doors.' It seems pretty clear, from these parts of the edict, that even at this early period the buildings of both cities had extended considerably beyond their respective gates, along the line of the highway between them; although probably they did not reach on either side as far as Charing Cross, which is supposed to have derived its name from a village called Charing, which anciently stood midway between London and Westminster.

The privilege which Westminster possessed, of holding a fair for forty days every year, was fenced with a prohibitory clause, by which, during all that time, no sales were permitted, either in London or in any of the places adjacent. As trade and population increased, the evil consequences of this monopoly came to be very severely felt by the citizens of London. The corporation, therefore, opened a negociation with the abbot, for the redemption of this part of their privilege, and found him so well disposed to prefer a present good to all prospective advantages, that for the sum of £8000 he abandoned the right to a fair altogether. By this stroke of priestly cupidity, Westminster, which

had been rising fast in commercial importance, was almost entirely cut off from this source of prosperity, and left to depend in future chiefly upon those advantages which it derived from being the residence of the court. The Genius of Trade took its leave of her for ever; and Fashion became henceforth the tutelary deity of Westminster.

On the general suppression of the monasteries by Henry VIII., that of Westminster was converted into a bishopric; but in 1550 the bishopric of Westminster merged in that of Norwich. It was this temporary possession of a mitre which conferred on Westminster the rank of a city; and, though the mitre is gone, the popular voice, inclining always to reason in its decisions, has refused to give an inferior title to a place, which, though no longer a bishop's see, is the seat of supreme power both in church and state.

Since that period, Westminster has spread so extremely on all sides, and become so interlaced with London, that the two cities have lost every external mark of separation, Temple Bar alone excepted. But see WESTMINSTER for some particulars of its history, into which we cannot now diverge.

6. *The great charter and early wealth of London.*—On the accession of king John to the throne, the citizens of London paid 3000 marks to him for a confirmation of their liberties. 'It shall be delivered to them,' said the royal mandate, 'on these terms, that if they will give those 3000 marks they shall have the charter; but if not, they shall not have it.' On the field of Runnymede, this mercenary tyrant was afterwards content to give them what they pleased, on their own terms. The general resistance which produced that glorious declaration of the rights of Englishmen, Magna Charta, had its first rise under the city banner. The castellan and standard bearer of London, at this period, was Robert Fitzwalter, a gallant knight of Norman descent, and lord of Baynard's Castle, an ancient and princely fabric, from which one of the wards of the city derived its name. This knight had a daughter, called Matilda the Fair, whose beauty attracted the admiration of the king. John came not, however, as an honorable suitor, and, when his proposals were repelled with indignation, he threatened to have recourse to violence. Fitzwalter appealed to his brother barons, to aid him in protecting his child from the polluting grasp of the tyrant. With honorable alacrity they obeyed the call; and, from the battlements of Baynard's Castle, the city banner waved defiance to aggression. John, whom a continued series of misdeeds had deprived of all favor with his subjects, was unable to muster a force sufficient to cope with so formidable an opposition; and, yielding reluctantly to the necessity of his situation, he affected to have abandoned all design against the honor of Fitzwalter's family, and, by the strongest assurances of respect for the rights of the barons, prevailed with them to disperse their forces. No sooner, however, did he find himself alone in the field, than he violated every promise he had made. Taking Fitzwalter by surprise, he compelled him to fly

the country; razed his castle of Baynard to the ground; and when the unfortunate Matilda, whom her father, in his sudden flight, had been forced to leave behind him, still resisted all his entreaties, he is said to have destroyed by poison that beauty which he could not enjoy. The day of retribution at length arrived. Fitzwalter had taken refuge in France, and fought on the side of the French in their battles with the English under king John. During the truce which took place, in 1214, an English knight rode into the space between the two armies, and challenged any one of the opposite side to a trial of prowess. Fitzwalter, mounted on a noble charger, instantly came forth to accept the challenge, and at the first course struck both the English champion and his horse to the ground. John, admiring the gallantry of the stranger, warmly exclaimed, 'He were a king, indeed, who had such a knight. Fitzwalter had been recognised by some old friends in the English camp, and, on hearing this observation from John, they kneeled down, and said, 'May it please your majesty, he is your own knight; it is Robert Fitzwalter.' John, repenting the injury he had done to the gallant knight, next day effected a reconciliation with him, and publicly restored to him all the possessions of which he had been so unjustly deprived. Fitzwalter, however, returned to England only to find new cause, in common with his fellow citizens, to detest the arbitrary rule of John; and we accordingly behold him again a leader against the king, in that patriotic struggle which obtained for England the great charter of its liberty. By the thirteenth article of this charter it is specially provided, 'That the city of London, and all other cities, burghs, and towns, and ports of the kingdom, shall enjoy all their free customs both by land and water.'

Of the military importance of the citizens of London, about this period, contemporary writers give us a very high idea. Although exempted by their charters from 'going to war,' they appear to have been naturally of so martial a temperament, and so forward in the assertion of their rights, even at the point of the sword, that William of Malmesbury assures us, they 'showed at a muster 20,000 armed horsemen, and 40,000 footmen, serviceable for the wars.' In this number, however, were doubtless included the followers of many noblemen and chiefs, who resided in the city, or who, from various causes, considered themselves identified with it; for so large a quota is wholly incompatible with every account we have of the ancient population of London.

Speaking of the commercial prosperity to which London had now reached, the same writer describes it as 'a noble city, renowned for the opulence of her citizens, and crowded with the merchants who resort thither with their various commodities.' Corn was still, as in the time of the Romans, their chief article of commerce; 'they had their granaries always filled, whence all parts of the kingdom were supplied.'

The commencement of the reign of John's successor, Henry II., presents us with a very striking display of the wealth for which the citizens of London were now, above all other classes of their fellow subjects, distinguished. When it

was known, that queen Eleanor was to ride through the city to be crowned at Westminster, the chief citizens, to the number of 360, preceded by a band of trumpeters, went out to welcome her majesty. They were all clothed in silken garments, richly embroidered with gold; and mounted on horses, most splendidly caparisoned. Every man bore a cup of gold or silver in his hand; and, having joined in the royal train, these 360 cup-bearers served the wine, as butlers, at the coronation of her majesty.

The prodigality and misrule of Henry soon destroyed that cordiality which, at first, subsisted between him and the city. When, however, his necessities became so great, that he was obliged to pawn the crown jewels for an immediate supply, it was to the citizens he was forced to have recourse. Angry that they should accept a pledge which it was ignominious in him to give, he passionately exclaimed, 'Were the treasures of Augustus Cæsar exposed to sale, the city would buy them. These fellows, who call themselves barons, are wallowing in wealth and every species of luxury, whilst we labor under the want of common necessities.'

When the citizens, however, had to deal with princes, not embarrassed through their personal follies, but impoverished by honorable enterprises for their country's benefit or renown, they stayed not for pledges to administer most liberally to their wants. They presented the hero of Cressy with a free gift of 20,000 marks, to pursue his honorable warfare in France; and their mayor, the celebrated Whittington, at an entertainment given at Guildhall to the hero of Agincourt, threw into a fire of spices, bonds which he held from that monarch, for money advanced, to the amount of no less than £60,000!

It must be allowed, indeed, that although the citizens of London were occasionally thus liberal, there was, in general, a considerable degree of reserve between the city and the court, on the score of money transactions. Till as late a period as the reign of Elizabeth, our sovereigns were obliged to have recourse to the merchants of Antwerp for such loans as they required; and though the citizens of London often became security for these loans, because without it they could not have been obtained, they could never be induced, except as in the case of Henry III., when the jewels of the crown were to be saved, to become themselves the lenders. Can any one be in doubt as to the reason? Notwithstanding all the charters, and confirmations of charters, granted by the sovereigns of England to their subjects, property was still insecure. A king of England might still deny to his own subjects that justice which he would not nor durst not, deny to those of another. The first considerable loan effected in England, solely on the personal security of an English monarch, was negotiated by Sir Thomas Gresham, in behalf of the maiden queen, and this fact we may regard as a certain indication that her government approached nearer to one of order and law, than England had ever known since the days of Alfred. Her majesty paid the interest of the loan regularly, until she was in a situation to discharge the principal; and it has been ever since found, that it is only necessary

VOL. XIII.

to observe the same simple rule of honesty, to find at home, and in London itself, whatever aid the exigencies of the public service require.

The opulence of the citizens of the olden time was in no instance more laudably displayed, than in doing honor to such illustrious strangers, as friendship to the monarch, or the chances of war, brought to England. In 1363 Henry Picard, who had some years before served the office of lord mayor, gave a splendid entertainment, at his house in Cheapside, to king Edward III., king John of France, king David of Scotland, and the king of Cyprus; an honor such as no citizen ever before enjoyed.

Among the citizens themselves there appears to have been a constant rivalry in sumptuous and costly living. A dish fit for an alderman, in those days, while turtle was as yet unknown, was one of eels, so lusciously dressed, as to cost about £5, equal to at least £80 of our present money.—Fitzstephen. At the annual Spittal feast, the cost to the sheriffs, for wine alone, was, about the middle of the sixteenth century, £600; so, that supposing the guests to have drank of Malmsey only, which, though the most choice wine of that period, cost no more than 1s. a gallon, there must have been emptied, on this occasion, the incredible number of 48,000 bottles! The expense of feasting became at length so excessive, that in 1554 the corporation found it necessary to pass a bye-law to restrain it. 'So huge and great,' says this curious document, had 'the charges of the mayoralty and shrievalty' become through this means, 'that almost all good citizens flee and refuse to serve in this honorable city, only because of the great excess and chargeable fare and diet, used in the time of the said offices.' To remedy this grievance, it was ordained, that no mayor, or sheriff, or alderman, or commoner, should have at dinner or supper more courses than one, and not more dishes at one course than six, whether hot or cold. Some curious reservations, however, follow, which show, on the part of the corporation, a prudent care to soften, as much as possible, the hardship of this limitation. It is provided, that 'one or two of the same six dishes may come to the board hot, as a reward, if they will, after the first three or five are served.' It is farther specially declared, that neither brawn, nor collops with eggs, nor sallads, nor pottage, nor butter, nor cheese, nor eggs, nor herrings, nor sprats, nor shrimps, nor any shell fish whatever, nor any kind of unbaked fruit, are to 'be accounted for any of the said number of dishes above-mentioned!' And moreover, as the guests could not be supposed, after such penurious fare, to have any disposition to make merry, it was decreed, that 'from henceforth neither mayors nor sheriffs shall keep any lord of misrule (merry andrew or fool), in any of their said houses.' All these regulations, it will be observed, had reference only to the private and family entertainments of the citizens; for, it is yet farther provided, that when a foreign ambassador, or any of the privy council, happens to be of the party, the feast may be 'amended and ordered,' at discretion.

In 1573 we find it again a matter of grave lamentation, that there should be such an excess

of good things at the tables of the chief magistrates, and of the companies; nay, at the very taverns and cook-shops, the consumption of venison, we are told, was shameful, 'insomuch that the court was much offended with it.' The common council, therefore, in order 'that the city might not continue to give the queen and nobility offence,' issued another commandment, by which they forbade all such extravagant feasting in future, except at their 'necessary meetings,' and ordered that, even on these necessary occasions, (most incredible sacrifice!), there should be no venison.

We have mentioned Whittington as entertaining the hero of Agincourt. The story of Sir Richard and his cat is not, after all, so remote from possibility as might be imagined. Mr. Southey, in his *History of the Brasils*, relates, that 'the first couple of cats which were carried to Cuyuba, sold for a pound (a pound's weight) of gold. There was a plague of cats in the settlement, and they (the cats) were purchased as a speculation, which proved an excellent one. Their first kittens produced thirty oitavas each; the next generation were worth twenty; and the price gradually fell as the inhabitants were stocked with these beautiful and useful creatures.' In the East, also, according to a Persian MS. quoted by Sir William Gore Ouseley, there is an island, which derived its name from a circumstance of the same kind; and Mr. Collet, an intelligent collector of relics, asserts, without hesitation, that the story of Whittington and his Cat is 'borrowed' from this tale of the East. It is scarcely necessary to remark, that there may have been a plague of rats, and that cats may have been worth their weight in gold, more than once since the world began. Although it is just possible, therefore, that the story of Whittington, as it exists in nursery records, may have had some foundation in fact, there are few who will not be desirous of a more probable explanation of his extraordinary rise in life. Foote, in his comedy of the *Nabob*, makes Sir Matthew Mite offer to the Society of Antiquaries a suggestion on the subject, which is not without ingenuity, whatever degree of truth it may possess.—'The commerce,' says Sir Matthew, 'which this worthy merchant carried on was chiefly confined to our coasts; for this purpose he constructed a vessel, which from its agility and lightness he aptly christened a cat. Nay, to this day, gentlemen, all our coals from Newcastle are imported in nothing but cats; from hence it appears, that it was not the whiskered, four-footed, mouse-killing cat, but the coasting, sailing, coal-carrying cat—that, gentlemen, was Whittington's cat.'

While Whittington was yet a boy, the burning of coal was considered such a public nuisance, that it was prohibited by an act of parliament, under pain of death; but it is singular enough, that by the time he had been 'thrice lord mayor of London' (1419), and although there is no trace of any repeal, in the interim, of the prohibitory statute, the importation of coal formed a considerable branch of the commerce of the Thames. 'As early as 1421,' says Mr. Brand in his *History of Newcastle*, 'it appears to be a trade of

great importance, and that a duty of 2d. per chaldron had been imposed upon it for some time.' To account for the trade having made such progress, while a statute against it remained unrepealed, and of such rigorous operation, that, according to a record in the tower, a person was once actually executed for offending against it (Sir Everard Home's *Dissertations*), we must suppose, that the crown had exercised that dispensing power, which it assumed in the earlier periods of our history, and had permitted to the lieges generally the importation of the forbidden commodity; or, what is more probable, because more consistent with the court practices of those days, granted to some favored individual a license to make his fortune, by infringing the law. It would be making a bold leap to a conclusion to say, that Sir Richard Whittington was the individual on whom this privilege was conferred; and yet the supposition is countenanced by a very strong declaration in the foundation charter of Whittington's College. The members of it are directed to remember in their prayers 'Richard the Second, and Thomas of Woodstock, duke of Gloucester, special lords and promoters of the said Richard Whittington;' showing distinctly, that it was to some special privilege or favor conferred on him by these princes, that he was indebted for his rise in life. It is farther extremely worthy of observation, that from the first opening of the coal trade in England, and for ages after, it had a reputation for making fortunes, only exceeded by that of the mines of Golconda and Peru.

Many circumstances thus combine to heighten the probability, that Sir Richard Whittington, who flourished at the same time with the commencement of this trade, was one of those who made a fortune by it; and that it was, as Sir Matthew says, 'the coasting, sailing, coal-carrying cat,' that was the real instrument of his aggrandisement. It had only to become a by-word, that by a cat and a king he had made his fortune; and popular invention would soon supply all the other lineaments of the story. In the print of Whittington by Elstrucke, he is represented with a grimalkin by his side, but Granger, our best historian of portraits, says, that it was substituted for a skull, which originally occupied its place, as the common people did not choose to purchase the print without their favorite traditional emblem.

Sir Richard was a liberal benefactor to the city, over which he had so often the honor to preside. At his own expense, he built the chapel of guildhall, and the library of Christ's Hospital; made large additions to the guildhall and St. Bartholemew's Hospital; and left funds to his executors for entirely rebuilding the prison of Newgate, which was previously in a most ruinous and miserable condition. He, besides, annexed to the church of St. Michael's a college of priests, called after his name, with an alms-house for thirteen poor persons; and to use the words of his executors, in the ordinances of the college, 'while he lived had ryghte liberal and large hands to the needy and poor.' The house in which Whittington resided is still to be seen in Swithin's-passage, Moor-lane.

7 *Ancient sports and pastimes.*—Let us come now,' as honest Fitzstephen says, 'to the sports and pastimes, seeing it is fit that a city should not only be commodious and serious, but also merry and sportful.' In the olden time, the inhabitants of the metropolis united the duties of the citizen with the relaxations and recreations of the country squire. Fitzstephen notices, that the citizens delighted in hawks and hounds, and the 'common hunt' still gives a yearly salary to an officer of the lord-mayor's household, whose duty it is to take care of a pack of hounds, which the corporation is entitled to keep. The exercise of hunting is now little indulged in by the citizens, 'not, however,' says Stowe, 'for want of taste for the amusement, but for want of leisure to pursue it.' The 'common hunt,' who used to purchase his place, which sometimes sold as high as £1500, had formerly a house in Finsbury-fields, where the hounds were kept, particularly 'the deep, full-mouthed hounds,' and he had a yearly salary and perquisites.

'In the holi lays all the summer,' says the same historian, 'the youths are exercised in leaping, dancing, shooting, wrestling, casting the stone, and practising their shields. The maidens trip with their timbrels, and dance as long as they can well see. 'In winter, every holiday before dinner, the bears prepared for brawn are set to fight, or else bulls or bears are baited. When the great fen, or moor, which watereth the walls of the city on the north side, is frozen, many young men play upon the ice: some striding as wide as they may, do slide swiftly; others make themselves seats of ice, as great as mill-stones. One sits down, many hand in hand do draw him, and one slipping on a sudden, all fall together. Some tie bones to their feet and under their heels, and, shoving themselves by a little picked staff do slide swiftly, as a bird flieth in the air, or an arrow out of a cross-bow.'

The most gallant of the youthful exercises of these times was that of running at the quintain. This game is of Roman origin. On an upright post, a cross bar was placed horizontally, which turned upon a swivel. A board was nailed to one end of this bar, and a bag of sand to the other. It was the custom to tilt against the board, on horseback, with a spear, or long staff; and it required great dexterity to avoid being struck with the bag of sand as it swung round. At this city exercise, in 1253, some of the household of Henry III., being present, chose to deride the performance of the citizens, who, resenting the affront, beat 'his majesty's servants severely.' For this act of just resentment, the city was fined 1000 marks. The fields were more usually the scene of this pastime; but it was frequently permitted even in the heart of the city. 'I have seen,' says Stowe, 'a quintain set up in Cornhill, near the Leadenhall, where the attendants on the lord of Merrydisports have run and made great pastime; for he that hit not the board end of the quintain, was of all men laughed to scorn.' The greatest feat which could be accomplished at this game was to break the board, and escape the revolving blow of the bag of sand. Whoever did so was accounted for the time 'Princeps Juventutis,' the prince or chief of the

youths. Plot, in his History of Oxfordshire, says, that this game was still to be met with in his time at Deddington; and Dr Kennet, bishop of Peterborough, mentions, that he had seen it at the village of Blackthorn, where he thinks it had been introduced as in London by the Romans, the Roman way lying through that village. At the Easter holidays there used to be a sort of water quintain on the river, where boats supplied the place of horses. The tilter stood with his lance in the prow, leaving the boat to be carried by the force of the stream against a shield suspended from a pole. If he broke his lance and kept his place in the boat, he was loudly applauded; but if, as was more frequently the case, the shock threw him into the water, 'there were upon the bridge, wharfs, and houses, by the river side, standing great numbers to see and laugh thereat.'

Archery became also a favorite game with the citizens, and was very successfully cultivated. It appears at one time, however, to have been supplanted by sports of a less noble order; for there is a writ extant, from Edward III. to the citizens of London, in which he thus reprimands them on the subject:—'the king, to the citizens of London, greeting: Because the people of our realm, as well of good quality as mean, have commonly in their sports, before these times, exercised the skill of shooting arrows, whence it is well known that honor and profit have accrued to our whole realm; and to us, by the help of God, no small assistance in our warlike acts; and, now the said skill being as it were wholly laid aside, the same people pleasing themselves in hurling of stones, and wood, and iron, and some hand ball, foot ball, bandy ball, and in lumbrik and cock fighting; and some also apply themselves to other dishonest games, and less profitable or useful, whereby the said realm is likely in a short time to become destitute of archers;' his majesty therefore commanded, 'every one of the said city, strong in body,' to cultivate the art of archery, and to leave off the other games to which they had betaken themselves, under pain of imprisonment. In consequence of this compulsory order, archery became speedily again the favorite amusement, and continued to be so, long after it had ceased to be of importance in a military point of view. In Henry VIII.'s time, it was as much in vogue as at any period of our history. The king himself was fond of it, and used to repair frequently to Mile End to witness the performances of the citizens. Many of the most skilful archers received nominal titles, as the duke of Shoreditch (a title given by the king to one Barlow), the marquis of Clerkenwell or Hogsden, earl of Pancras, &c. In the year 1583 there was a great shooting match, when a vast body of the citizens marched in great pomp, singularly dressed, through the principal streets of London, to Smithfield, the scene of contest. Their attire is said to have been very gorgeous; 942 of them wearing chains of gold. The number of archers that shot was 3000, and their attendants exceeded that number.

Wrestling was another favorite amusement, and the lord mayor and citizens frequently

attended to encourage the youths engaged in this athletic game at Clerkenwell. In the year 1222, at a match of wrestling near St. Giles's, the citizens challenged those in the suburbs and city of Westminster, and beat them, which so irritated the bailiff of Westminster, that he determined on a base and treacherous revenge. He proclaimed a game to be held at Westminster on Lammas day, to which the citizens were invited, and attended. When they had played some time, the bailiff, with a large party, suddenly furnished themselves with arms, and treacherously attacked the citizens, who, being unarmed, fled to the city, where they sounded the alarm, by ringing the common bell. The citizens assembled in great numbers, eager for revenge, when one Constantine Fitz-Arnult, notwithstanding the remonstrance of the lord mayor, who promised to obtain redress, urged the multitude to join him in pulling down the house of the abbot of Westminster, and several others. A few days afterwards, the chief justice of England, Hubert de Burgh, with a great army of men, repaired to the Tower, and, sending for the lord mayor and aldermen, demanded the ring-leaders. Constantine gave himself up, and, with two others, was executed next morning, although he offered 15,000 marks for his life.

As the fields around London came, in the progress of improvement, to be divided and enclosed, the tilting at the quintain, archery, wrestling, and all other field sports, began to decline; and, at the period at which we have now arrived, they have entirely disappeared. In 1514 much discontent prevailed among the populace, on account of the abridgments which were constantly taking place in the theatre of their rural pastimes; and being stirred up by a fellow who went about disguised in the dress of a merry-andrew, calling out for spades and shovels, they resolved to take the work of redress into their own hands. A great multitude of them assembling, armed with these weapons, they soon levelled with the ground all the newly erected fences and enclosures about Shoreditch, Hoxton, Islington, &c. Government censured the magistrates severely for neglect of duty in not preventing this tumultuary proceeding; but that cannot be considered as a proceeding altogether without apology, which the government itself, about a century after, sanctioned by an act of its own as nearly similar (in intention at least) as possible. James I., in the eighth of his reign, granted a commission to several persons of distinction, for the purpose, he states, of stopping the practice of enclosing the ground formerly used for archery, by making of banks and hedges in such fields and closes, as, time out of mind, were allowed to be shot in. It empowers the commissioners to go upon these places, and to view and survey in such grounds next adjoining to the city of London and the suburbs, within two miles compass; and the same to reduce in such order and state for the archers, as they were in the reign of king Henry VIII., and to cause the banks, ditches, and quicksets, to be made plain and reformed. It is scarcely necessary to state, that this commission was never carried into effect; nor would it now be of any avail to en-

quire into the causes which made it inoperative. That it would have been injurious to the public interest, and oppressively unjust to individuals, had it been fully executed, must be sufficiently obvious; but we may be permitted to regret, that it should have been so entirely neglected, and the cultivation of the robust virtues so much disregarded, that a population of about 1,000,000 of souls is now left with scarcely a single open spot on which they can indulge in athletic and manly exercises.

Excluded from the fields, the citizens were forced to turn to such pastimes as the narrower limits of their streets, courts, and squares, and the safety of the passengers, would allow. The proscribed games of the days of Edward III., hand-ball, foot-ball, throwing of bars, cock-fighting, &c., came again into fashion; and hence the skittle-grounds, bowling-greens, tennis-courts, which now form the chief resorts of the London artizans, in their hours of recreation.

It appears, that, even as late as the time of Charles II., the citizens were still allowed, without hindrance, to make the streets the scene of their most boisterous amusements. Sir William Davenant, in a satirical description which he gives of London at this time, in a letter to a friend, says, 'I would now make a safe retreat, but that, methinks, I am stopped by one of your heroic games, called foot-ball, which, I conceive (under your favor), not very conveniently civil in the streets, especially in such irregular and narrow roads as Crooked Lane. Yet it argues your courage, much like your military pastime of throwing at cocks; but your metal would be much magnified (since you have long allowed these two valiant exercises in the streets), to draw your archers from Finsbury, and during high market let them shoot at butts in Cheapside.' The citizens (under favor to Davenant) had some reason to complain, that the streets alone were left them to exercise in; and it was thought prudent probably, to allow their feelings on the subject to die away, before the municipal government interfered to put a stop to what must indeed have been a great nuisance.

The most celebrated holiday of early times was May-day. A may-pole, or shaft, used to be erected on that occasion in the middle of the street, before the church of St. Andrew Undershaft, of such height, that it overtopped the steeple; and hence it was that the parish, which was originally called St. Andrew only, acquired the addition of Undershaft. Chaucer, describing a lofty bragart, says, he bears his head as high as the great shaft of Cornhill.

The arrival of this day of festivity used to be anticipated by the people with such eagerness, that Shakspeare speaks of them as being unable to go to sleep on May-eve. One evil May-day, however, occurred, and never again did May morn come to the citizens of London wreathed in its usual smiles. In consequence of an insurrection which broke out in London, on May-eve, 1517, the sports of May-day were long suspended; nor were they, ever after, more than very partially resumed.

The game in universal use within doors, for many centuries, was that most seductive of all

games of hazard—dice; nor is it possible, that it could have been indulged in to the extent we find it was, without being attended with all the most ruinous consequences of gaming. When Henry Picard had the honor of feasting four kings at his house in Cheapside, in the year 1363, we are told, that after these illustrious guests were gone, he kept his hall for all comers that were willing to play at dice and hazard; and that, in like manner, the lady Margaret, his wife, kept her chamber to the same intent. During the Christmas holidays of 1377 a party of the citizens, to the amount of 130, went a mumming, as it was called (in masks, representing kings, emperors, &c.) to Kennington, in order to pay their respects to Richard, the son of the Black Prince, who was residing there with his mother. After the mummers were introduced to the young prince, they put a pair of dice on the table, and invited him to try his luck with them. The first stake they proposed was a bowl of gold; the second a cup of gold; the last a gold ring; and it was so managed that the prince won every throw. The prince's mother, his uncle, the duke of Lancaster, and many other noblemen who were present, were also successively invited to take the chance of the die for a gold ring; and as certainly as they tried they won. It must be allowed, that there was an air of gallantry in all this; but what can be said for the moral sentiments of an age when false dice could be made the passports to princely favor? The vice of gaming did not confine itself to private society; for we find that, as early as the beginning of the sixteenth century, there were public gaming houses in the city, to which habitual gamblers resorted in great numbers. They were situated chiefly about the Exchange, in the parish of St. Bennet Finke. In 1551 an information was laid against one of these houses in the Exchequer, and five of the parties concerned in it fined 40s. each. James I. seems to have thought that this mode of amusement was as commendable as any other, for he granted a privilege to his groom porter, Clement Cottrel, to license, within the limits of London and Westminster, and two miles thereof, no fewer than forty taverns, 'for honest and reasonable recreation of good and civil people, who for their quality and ability may lawfully use the games of bowling, tennis, dice, cards, tables, nine-holes, or any other game hereafter to be invented.'

PART II.

CIVIL AND MODERN HISTORY.

Early civil government.—The civil government of the city has varied considerably under the successive domination of the Romans, Saxons, Danes, and Normans. In the early period of the Roman sway in Britain, it was entirely military; but the growing importance of the city soon raised it to the rank of a colony, which entitled it to peculiar privileges. The government then became assimilated to that of Rome; the chief magistrate was a prefect, appointed by the parent state, and the inhabitants were considered as Roman citizens.

Under the dominion of the Saxons, and of our

great lawgiver Alfred, the civil institutions of the metropolis, like those of all the rest of the country, appear to have been modelled anew, and in a manner so wise, that they have retained the form then given them through all succeeding ages. It was Alfred who first divided the kingdom into shires or counties, the counties into hundreds, and the hundreds into tythings, in order that, by this subdivision of jurisdiction, peace and order in the community might be the better preserved; and, though our histories are silent as to the extension of this system to the metropolis of the kingdom, the evidence of analogy is strong enough to warrant us in concluding, that it was from Alfred also that London first derived its sheriff (shire-reve), and its division into wards and precincts, under the government of ealdermen or aldermen, and their deputies. When it is considered, likewise, that every search which has been made into the antiquity of these offices has reached back to the Saxon time, and there stopped, all doubt must vanish as to the source from which they sprung. The civil government of London, and that of the country at large, can have had but one common parent—the great, the good, the enlightened Alfred.

The office of sheriff being purely executive, and the aldermen all of equal power, it became necessary, for the completion of the municipal scheme of polity, that there should be one supreme governor or magistrate (the eldest among the aldermen), who might superintend the conduct of the rest, in their respective jurisdictions, preside over them in their collective deliberations, be the organ of the city's will, and, more peculiarly than any other, the guardian of its interests. The officer on whom this power was conferred was styled, by the Saxons, the port-geref or port-reve. The duration of his office was limited to one year; but it does not appear whether he was elected to it by the citizens themselves, or nominated by the king. The Normans retained the port-reve, but appear on some occasions to have associated with him another officer, called a provost. Of the manner in which the duties of the office were divided between them we have no account. No instance of the chief magistracy being thus put in commission occurs later than the accession of Henry II.

In the first year of Richard I., according to Stow (1189), the city 'obtained to be governed by two bailiffs, which bailiffs are, in divers ancient deeds, called shrives,' i. e. sheriffs; and it has been from this hastily inferred, by some writers, that these bailiffs superseded both port-reve and provost. The statement appears to us, however, to mean only that the office of sheriff had been then first split into two; for it is a vulgar error which prevails that it is because of the annexation of the sheriffalty of Middlesex, to that of London, that there are two sheriffs. The division of the office took place some years anterior to that annexation; and the reason for it was, that London is by charter both a city and a county within itself. It is certain that, in the fourth year of Richard's reign, only three years after this supposed innovation of the two

bailiffs, the chief magistracy was vested in one person as usual; for it was in that year that Henry Fitz Alwyn, being then governor or port-reve, assumed the title of mayor, and placed himself first in that long line of worthies who have done honor to the name and office. While Fitz Alwyn lived the mayoralty remained, by a sort of courtesy, vested in his person, and was filled in a manner free from reproach; but on his death, in the twenty-fourth year of his civic administration, the citizens manifested a very proper anxiety to have the office placed on a more constitutional basis. King John was desirous of conciliating their good will at this time, and they obtained from him, without difficulty, a charter, by which the crown conceded to them the liberty of choosing a mayor annually out of their own body, and continuing him at their own pleasure from year to year.

The oppressive conduct of John towards the city at a later period, put its rights in jeopardy for a season, but served in the end to bring about a course of events which placed them on a still surer foundation. In the great charter it was declared, among other things, that the 'city of London should have all its ancient privileges, and free customs, as well by land as by water.'

In the ignominious times of Henry III., and particularly when that monarch was under the influence of the justiciary Hubert de Burgh, the privileges of the citizens of London were repeatedly invaded, in the most wanton manner, by the crown. In consequence of the tumult which we have before related (*Ancient Sports and Pastimes*), for inciting which Constantine Fitz Arnulph and others were executed, the justiciary thought proper to degrade the mayor and aldermen from their functions, on the pretence of their not having exerted themselves sufficiently to preserve the peace. He then transferred the government of the city to a custos or keeper of his own nomination, and selected thirty of the principal inhabitants, whom he obliged to sign a bond for the future good conduct of their fellow citizens. The real character of these measures may be gathered from the fact, that in a short time after the citizens were permitted to purchase back the rights of which they had been thus violently deprived. Stowe says, that the price amounted to 'many thousand marks.' The whole of Henry's conduct towards the citizens of London was, in fact, one continued system of extortion and oppression. After granting them five charters, four of which were merely confirmatory, and the fifth of small importance, he exacted from them, by way of fine for these five grants, a fifteenth of all their personal estates. At another time he obliged them to make him a present of 5000 marks, because they had given a like sum to prince Louis of France, when, along with the barons, they sided with that prince against king John. At Christmas he would take up his abode in the city, and compel the citizens, not only to present him with valuable new years' gifts, but to feast the whole court in the most sumptuous and extravagant manner. Not a single act of misgovernment, whether proceeding from the worst or the lightest of motives, was suffered to pass without being made the pretext for some

new exaction, some new punishment. Twice was the government of the city again taken out of the hands of its own magistrates and transferred to custodes, nominated by the king; and as often was it restored to them on the usual condition of paying handsomely for getting back their own. When such deprivations had not the effect contemplated by royal cupidity, the magistrates were cast into prison, and detained there till presents of plate and money appeased the anger of their sovereign. Neither person nor property was safe from the grasp of the tyrant. Apprehensive, at last, that he would strip them of all they possessed, they collected £10,000 of their money, and deposited it in the treasury of the knight's templars at the New Temple, conceiving that from the sanctity of the place it would there be safe from spoliation. Prince Edward, the king's son, however, immediately went and broke open the treasury, and took away the whole of the money. The citizens could be quiescent no longer; and immediately flew to arms, resolved on asserting their undoubted right of resistance to a reign of plunder and oppression. The barons had already unfurled their banners, and the citizens of London joined them in great numbers. In the battle of Lewes there were 15,000 of them present, who suffered most severely; for, though the king's army was defeated, the Londoners reaped none of the laurels. Prince Edward, having made the city column the object of his principal attack, put it to the route and pursued it with relentless slaughter for four miles; but while thus absent from the field, Simon de Montfort and his brother barons were gaining advantages, which ultimately decided the victory in their favor. The affairs of the king were, however, retrieved by the triumph at Evesham in the following year, and vengeance now fell with a heavy hand on all who had been concerned in this luckless effort for freedom.

A parliament was assembled at Westminster, by which it was enacted, 'that the city of London for its late rebellion should be divested of its liberties, its posts and chains taken away, and its principal citizens imprisoned and left to the mercy of the king.' The citizens endeavoured in vain to propitiate that 'mercy' to which they were thus consigned, by the most humble supplications. The act of parliament had been purposely so framed, that the king might again rob and oppress them to the utmost; and never had a wicked law a more zealous executor. He seized on the estates, houses, and personal effects of many of the chief citizens, and consigned four of the richest to dungeons till they paid enormous sums for their ransom. Nor did he stay the work of spoliation, till the citizens came forward with a general contribution of 20,000 marks, which, owing to the exhausted state of the city, was collected with so much difficulty, that even servants and lodgers were obliged to be included in the assessment. The pardon which it procured from Henry amounted after all to no more than an exemption from farther pillage; for the chartered rights of the citizens Henry still withheld. Four custodes were appointed to rule the city, according to their own discretion; and the citizens were left without

the smallest share in the direction of its affairs. After they had remained three years under this arbitrary sway, the king so far relented, that, by a charter, dated in March, 1268, he remitted all past offences, and confirmed all the ancient privileges of the city, with this important exception, that they should continue deprived of the right of electing their own magistrates. In 1270, however, prince Edward, being appointed governor of the city, prevailed with the king to concede also the excepted privilege, and thus restored the citizens to the full enjoyment of all their ancient institutions.

On the accession of Edward I. Gregory de Rokeslie was mayor of London, and a man of so much talent and consideration, that the king employed him to execute a foreign mission of considerable importance, in preference to many dignitaries in church and state, who solicited the appointment. In order to provide for the government of the city, during the mayor's absence, the king addressed a writ to the corporation, directing them 'to appoint four respectable and discreet persons, whom he might commission, during the mayor's absence, to preserve peace and good order, and to administer justice within the city's jurisdiction.' It would seem that Rokeslie had subsequently fallen into disfavor, for we find that, in his person, the dignity and privileges of the mayoralty were afterwards very grossly violated. In 1286 the mayor, sheriffs, aldermen, and other eminent citizens, were summoned to make inquisition at the tower, before John de Kirkeby, treasurer, and other justices of the king. It was, however, one of the ancient privileges of the city, that the corporation should not be bound to make inquisition in the tower, nor appear there, *pro judicio*, unless on a previous notice of forty days. The mayor, therefore, previous to obeying the summons, resigned the common seal of the city to Stephen Aswy, and other aldermen: and at Barking church, which is on the eastern verge of the city, laid down the insignia of his office. He then entered the tower, not as mayor but as a private individual, and, when an explanation of this conduct was demanded from him, he asserted firmly the rights of the city.

The treasurer immediately declared the office of mayor and the liberties of London forfeited to the king, giving as a reason, the odious fiction, that, as Rokeslie had divested himself of the seal and insignia of office, the city had no longer any chief magistrate. Eighty of the principal citizens repaired to Westminster Hall, to remonstrate against this usurpation, but for their temerity were arrested, and thrown into prison. For four days were this numerous and respectable deputation thus immured, and then, without apology or explanation, dismissed to their homes. The king now appointed Sir Radulph de Sandwich, knight, *custos*, in place of the mayor, with orders at the same time to govern the city according to its ancient customs and liberties. Sir Radulph and Sir John Breton were alternately *custodes*, until the year 1298, when the king allowed the citizens again to choose their own mayor, though not till they had made him a gift of 20,000 marks. But many years were not suffered to elapse before

the citizens had again to complain of infractions of their rights; arising in this instance, however, not from external aggression, but from corruption among themselves. The mayor and aldermen began to assume the right of continuing themselves in office during pleasure; and when they resigned it was but for a season, for the sake of preserving appearances, and to persons of their own appointment. They imposed taxes too upon the citizens, and disposed of the money derived from them, as well as of the whole revenue of the city, in any manner they pleased. From 1315 to 1322 the discontents and upbraidings, which these lawless usurpations occasioned, kept the city in a state of continual ferment. In 1318 articles of agreement were, through the mediation of the king (Edward II.), entered into between the citizens and their magistrates, for a redress of grievances; but, if observed at all, it was only for a short period. No permanent redress followed, and the city still continued a prey to the tyranny of a self-elected few. Edward, at length, on the specious pretext of putting an end to this state of things, took the government of the city into his own hands. Shortly after, indeed, he gave permission to the aldermen and commonalty to elect their own mayor; but a gift of £2000, which they immediately presented to him, told the price at which their rights were redeemed from this double usurpation.

When the attachment of Edward to his favorites, the Spensers, drove his queen, Isabella, and the barons, into rebellion, the citizens of London having evinced a disposition to take part with the latter, the king again seized upon the government of the city, and appointed Walter Stapleton, bishop of Exeter, *custos*. The bishop proceeded accordingly to demand the keys from the mayor; but the citizens, assembling in great numbers around their chief magistrate, not only obliged him to maintain possession of the symbols of authority, but, laying hold of the unlucky prelate, proclaimed him a traitor and cut off his head.

The citizens now declared openly for the queen; seized and executed a number of persons whom they supposed to be her enemies; made themselves masters of the tower; dismissed all the king's officers; and placed both the city and tower at the command of those who were engaged in the righteous cause of freeing the country from the bondage of favoritism. The king, unable to stem the torrent of popular indignation, was defeated, taken prisoner, and deposed. Isabella entered London in triumph, and transferred to her son, Edward III., that crown which his father had so unworthily worn.

In return for the services which the citizens had rendered at this crisis, Edward III., within two months after his accession, granted them a most ample confirmation and enlargement of their corporate privileges. He not only confirmed all the ancient rights of the city, whether founded upon charter or custom, and annulled every innovation upon them that had been made from the earliest times, and in whatever manner; but, in order to prevent any future infraction or suspension of them, on account of any real or pretended misconduct of persons temporarily in-

vested with the administration of the city government, it was expressly declared, 'that for any personal transgression, or personal judgment of any minister of the same city, the liberty of this city should not be taken into the hands of the king, or his heirs; nor a custos be deputed on that occasion in the same city.' Edward continued, throughout his reign, to pay a strict regard to the privileges which he had thus solemnly confirmed and extended. In the days of his dotage, a report prevailed, that it had been proposed in council, to abrogate or suspend them, on account of the part which the citizens took against the celebrated Wickliff; but, though there is evidence of their having opposed the spread of the reformation, there is none of their having received the punishment which their bigotry deserved. A synod had been held at St. Paul's, to pass judgment on Wickliff for the new opinions which he then maintained in religious matters. The apostle of reform made his appearance before the tribunal, accompanied by the duke of Lancaster and the earl marshal of England, as his friends and protectors. In the course of the proceedings, a dispute arose between the duke and the bishop of London, in which the citizens espoused the cause of their spiritual chief so warmly, that the duke and earl marshal thought it prudent to withdraw with the accused. A rumor was next day spread abroad that the duke, out of resentment, had moved in council, that the city privileges should be taken away, the office of lord mayor abolished, and the government of the city entrusted to the earl marshal. The citizens immediately assembled, in a most tumultuous manner, broke open the marshal's prison (the marshalsea), and liberated the prisoners; then proceeded to the duke of Lancaster's palace, in the Savoy, which they plundered, and, missing the prince himself, made prize of his coat of armour, which they dragged along the streets in token of their detestation of the owner. Had no proposition of the kind been agitated in council, such conduct was of itself sufficient to provoke the most exemplary punishment. The duke, however, contented himself with insisting on the degradation merely of the mayor and certain of the aldermen; who appeared not to have exerted themselves with sufficient vigor in quelling the riot.

In the time of Richard II. the reign of rapacity returned, and the citizens of London were again doomed to suffer largely in their property for the preservation of their privileges. In one of the many pecuniary difficulties in which this prince was involved, by his prodigal habits, he made a demand on the city, for the loan of £1000. The city not only refused the money, but when a Lombard merchant, of more exuberant loyalty, offered to make the advance out of his own purse, they chastised him severely for his officiousness. They seem to have been actuated less by a regard for the money itself, than an honest desire to check the profusion in which Richard indulged to a degree beyond all preceding example. The moral censorship which they chose to exercise, cost them, however, dear. Richard called his nobles together, to whom he represented, in indignant terms, the presumption

and maliciousness of 'these Londoners,' and with their concurrence suspended the mayor, aldermen, and sheriffs, from their offices; revoked and annulled the whole of the rights and privileges of the city; removed the courts of law to York and Nottingham; ordered the magistrates to pay into the royal treasury the sum of 3000 marks, and the commonalty the more enormous sum of £100,000 (Rymer's *Fœdera*, Vol. VII. p. 785), and in the mean time committed the mayor and other principal citizens to different and distant prisons, there to remain till these fines were paid. Nor were they even then to expect restoration to favor; for it was decreed, that in future the citizens should have no government of their own; but that the king should appoint one of his knights to be ruler of the city.

It was not long before the king showed a disposition to commute these severe penalties; which seem indeed to have been made thus severe for the very purpose of enabling his majesty the more readily to turn the remission of them to profitable account. The citizens appreciated the character of his majesty's proceedings quite correctly, when, as Stowe informs us, they concluded that, 'the end of these things was a money matter.' They first tried the cupidity of the king with an offer of £10,000 for a restoration of their privileges, but this proposal was not thought worthy of an answer. Soon after, however, they were informed that the king had taken compassion on them, and meant, with his queen, to pay the city a visit, when they would have an opportunity of showing, by the reception they gave their majesties, how far they were deserving of the royal favor. Richard, having set out on this visit of conciliation from his palace at Sheen, was met at Wandsworth by 400 of the principal inhabitants, mounted on horseback, who tendered the humble submission of the city, and besought his majesty's gracious pardon for all its past offences. As he entered the city his coming was greeted with the acclamations and blessings of assembled thousands; in all the streets through which he passed the houses were decorated with cloths of gold, silver, and silk; the conduits ran with the choicest wines; and at every step the most costly gifts were heaped on the monarch and his queen. Crowns and tables and vessels of gold; horses proudly caparisoned: cloths of the richest fabrics; coins, jewels, and precious stones; are enumerated among the offerings made on this occasion by an injured people, to appease the wrath of their sovereign. Well might the citizens imagine, that their pardon was now secure; yet, profuse as they had been, Richard was still unsatisfied. He insisted on having a further gift of £10,000 in money; and not until this sum was collected by an assessment on the inhabitants, and paid into the royal coffers, would he consent to restore the city to its privileges, and remit the fines of 3000 marks and £100,000, which he had originally imposed on the magistrates and commonalty. Such is the compassion of tyrants; such the 'good old times,' which ought to make the citizens of London reckon, as above all price, the constitutional liberty which they now enjoy. Every care was taken not to furnish Richard with any new pretext for interfering with the city; but,

when he could no longer plunder it under disguise of the royal prerogative, he did not hesitate to have recourse to open force. In 1397, without any pretext whatever, he extorted from the city, in its corporate capacity, 10,000 marks, and in the following year levied still larger sums from individual citizens. The tyranny of Richard, however, was now drawing to its termination. The universal disaffection which it had produced encouraged Henry of Bolingbroke to hoist the standard of rebellion; Richard was in an instant hurled from his throne; and those streets which had been so lately paved, as it were, with diamonds at his approach—where he had witnessed far more loyalty than he knew how to appreciate—saw him led captive to the tower, without one token of that commiseration which the fall of greatness usually inspires.

Henry IV. gave the citizens no cause to regret his accession to the throne; while he lived he respected their institutions, and granted them several new privileges highly conducive to the good government of the city, particularly a more absolute control than they had yet possessed over the different gates and posterns. During the splendid reign of Henry V., and that of his son Henry VI., while under the beneficent protectorate of the great duke of Bedford, the government of the city was left, without interference, in the hands of its own magistrates, and never, perhaps, was that government more ably or prosperously administered.

When the turbulent cardinal Beaufort endeavoured, in the absence of the protector in France, to wrest the reins of power from the hands of the deputy protector, the good duke Humphry of Gloucester; he commenced with an attempt to get possession of London by surprise, while the citizens were engaged in the annual festivity of welcoming their chief magistrate into office; but through the vigilant and spirited conduct of the mayor, Sir John Coventry, the design was happily frustrated.

After the assumption of the sceptre by Henry VI., the loyalty of the citizens of London was assailed by many temptations; but they were slow in participating in the party feuds which the misgovernment of this imbecile prince produced. The good service which they rendered Henry on the occasion of Jack Cade's, or rather Richard duke of York's insurrection, as already related appears to have arisen, more from a wish to rid the city of a troublesome guest than from any affection for the prince himself; nor was it till a considerable time after war was openly declared, between the rival houses of York and Lancaster, that they declared for either. In 1458 it was selected as a sort of neutral ground where the chiefs of the adverse parties might meet to treat of terms of accommodation; and the manner in which its magistrates conducted themselves, on the occasion, did singular honor to their impartiality and firmness. From a distrust of each other's good faith, the leaders of both parties came to the conference attended by numerous retinues of armed men; and, to preserve the peace of the city from the imminent danger to which it was exposed by so numerous a confluence of hostile spirits, the mayor, Sir Godfrey

Boleyn (ancestor to the queens, Ann Boleyn and Elizabeth), caused a guard of 5000 well armed citizens to keep watch day and night. So imposing a force kept both the Yorkists and Lancastrians in awe, while it showed that possession of the city was a prize to be hoped for, at present, by neither. After many communings, articles of reconciliation were at length agreed to, and celebrated with abundant solemnity in St. Paul's cathedral; but founded in mutual insincerity and deceit, the parties separated only to appeal anew to the decision of arms.

The citizens now thought it incumbent on them to depart from that line of neutrality which they had hitherto observed. The miseries of civil war were no longer to be averted; and they felt, as all true patriots must feel in such cases, that it was their duty to throw their weight where it might have most influence in bringing these miseries to a speedy termination. The side which the Londoners espoused was that, in fact, which ultimately triumphed. The duke of York was established on the throne, by the title of Edward IV., and manifested his gratitude to the citizens, for the services they had rendered to his cause, by several important grants, which added considerably both to the jurisdiction and to the revenue of the corporation.

The union of the houses of York and Lancaster, though in its general results auspicious to the nation, was less immediately so to the citizens of London, than to any other portion of the community. The reign of the first of the Tudors, though distinguished by a policy well suited to the character of the times, was stained by many acts of grievous oppression towards the citizens of London. The master passion of Henry's breast was avarice; and, to fill his coffers, he had recourse to modes of extortion quite as odious as those by which Henry III. and Richard II. fed the streams of their thriftless prodigality. He did not, like them, traffic in taking away privileges that he might make money by restoring them; he showed every respect for the ancient and undoubted right of the citizens to elect their own magistrates, but took the liberty at the same time of asserting his own right to determine whether their magistrates did their duty, and to fine them smartly for whatever, in the omnipotence of his discrimination, he chose to brand with the name of malversation. The ingenuity of this mode of spoliation was considerable; since it made the citizens themselves the purveyors, and, the worse the magistrate, the more certain he was to enrich the sovereign. Civic honors became now the greatest of all individual misfortunes; to be elected into office was to be marked out as a victim for royal rapacity. Sir W. Capel, who filled the mayoralty in 1503, was, five years after, on a general allegation of remissness in his official duties, fined £2000; and, because he refused to submit to the iniquitous exaction, was committed a close prisoner to the tower. Sir Thomas Kniesworth, who was mayor in 1505, and his two sheriffs, paid the sum of £1400 to escape a similar fate. Sir Lawrence Aylmer, who filled the mayoralty in 1507, and his two sheriffs, preferred the example of Capel, and followed

him to prison rather than pay the heavy fines which were demanded from them. An alderman of the name of Hawes was also imprisoned for some pretended misconduct in his official capacity, which affected him so much that he died of a broken heart.

The accession of Henry VIII. opened the prison gates to Capel and the other victims of his predecessor's tyranny; while Empson and Dudley, who had been the chief agents in these schemes of extortion, expiated by their lives the infamy of their employment. With 'a generous magnanimity, not uncommon in the world, the new king gave up the offenders, and profited by the offence; sent the collectors to the scaffold, and kept the money in his treasury.'

During this reign, despotic and sanguinary as it was, the corporate privileges of the city of London were more respected than they had been for many a preceding age. The events of Evil May-day exhibited as remarkable an example of misgovernment as is perhaps to be found in the city annals; but though there was humiliation, and shame, and reproach, in the treatment which the magistrates experienced from Henry on the occasion, it was attended with no resumption, no infringement of charters. The citizens, too, went farther than they had ever yet done, in opposing the pretensions of the crown to levy taxes of its own authority; but with the exception of one stubborn patriot, who was seized and sent to the wars on account of the lead which he took in this opposition, they suffered no harm for their spirited conduct; Henry even withdrew his pretensions, and disavowed the authority by which they had been put forward.

In the reign of Mary, the civil government of the city suffered a temporary suspension during the formidable rebellion of Sir Thomas Wyatt. The Londoners were suspected, and not without reason, of being favorable to the cause of the rebels. The city was, therefore, placed under the military command of lord William Howard, as her majesty's lieutenant; and it was by his spirited conduct in defending it, when attacked by the insurgents, that the rebellion was ultimately defeated.

When Elizabeth succeeded to the throne, she administered the government of the kingdom, in all its parts, so arbitrarily, and yet so well, by the mere force of her personal talents, that the privileges of the city of London, like every other free institution of the country, were lost to the sight, amid the glories of her unrivalled reign. The metropolis was at all times an object of her peculiar care; and, in her own person, she may be said to have at once united the various functions of counsellor, alderman, and chief magistrate. The persons who filled the different civil offices, during her reign, were in general the mere instruments of her will. The power she exercised was unlimited; but tempered with so steady a regard to the interests and honor of her people, as to gain her their unanimous esteem and confidence. The numerous and large demands which were made on the city, during her reign, for men and money, were obeyed with an alacrity, which showed that she had their hearts and purses equally at her command. It is remarked by his-

torians, as a singular circumstance, that such devotion, as the citizens of London displayed to Elizabeth, should not have been rewarded by any new privileges, nor even by a confirmation of those which had been granted to them by her predecessors. The fact, however, is but in harmony with the character of her reign. She ruled well, not by virtue of wax and parchment. She made the days forgotten when charters were worth caring about, by showing how easy it is for a good and wise monarch to make a people happy without them; and she left besides, in her example, what ought to have been of more weight with her successors than 10,000 charters.

James I., with talents for ruling vastly inferior to those of Elizabeth, endeavoured to govern the kingdom on the same absolute principle; but governing it weakly, and ingloriously—exerting power more for its own sake than for any good it could confer—he brought odium on himself, and disaster on his race, by the experiment. The citizens of London, however, were among those who suffered the least from his arbitrary pretensions; for, sensible of the importance of cultivating their good opinion, he treated them at all times with peculiar kindness and respect. He became a member of several of their companies; he honored their public feasts with his presence; he borrowed repeatedly large sums of money from them, which he repaid punctually, though in his general habits careless and profuse; and he extended and confirmed the city's jurisdiction by more than one valuable charter. The local government of the city, which had been in a manner superseded during the reign of Elizabeth, now resumed its functions; and, in one remarkable instance, we find it even opposing itself to the general government of the sovereign.—After James had published his Book of Sports, by which a general toleration was given to break the Lord's day, his majesty happening one Sunday to drive through London during divine service, in contempt of one of the city's regulations, the lord mayor (the Right Hon. George Bolles) had the spirit and firmness to order the king's carriages to be stopped. 'What!' exclaimed James, swollen with rage, 'I thought there had been ne'er a king in England but myself.' He immediately despatched a messenger to the lord mayor, with his royal commands to let the carriages pass. 'While it was in my power,' replied the worthy magistrate, 'I did my duty; but, that being taken away by a higher power, it is my duty to obey.' It is said that James had, the good sense to do justice to the spirit which dictated this conduct, and thanked the mayor for knowing the duties of his office so well.

Charles I., acting upon his father's extravagant notions of the kingly prerogative, while the advancing intelligence of the age was daily rendering them more and more intolerable, the patience of the people became at length exhausted, and they had recourse to arms to re-assert their violated liberties. In this necessary effort, the city of London, which had suffered more than any other part of the kingdom from the oppression of the king, took a leading and important part; from first to last it was the life and soul of the independent cause; and, but for its perseverance,

firmness, and sacrifices, it seems more than probable that the nation would, at this time, have sunk at the feet of despotism. From being so directly under the eye of the star chamber and high commission courts, it had opportunities of witnessing too many of those 'fantastic tricks,' which make 'even angels weep,' to abandon easily the attempt to be free.—It had seen its most venerated institutions set at nought; martial law substituted for civic rule; trade and industry made matters of privilege and monopoly; the property of the citizens plundered by illegal exactions; the richer sort thrown into prison when they refused compliance, and the poorer dragged to serve in the army and navy. It had seen the king repenting himself of these severities, when he found them less productive to his treasury than he expected, and by a formal charter (18th October, 1638) confirming and restoring to the citizens 'every right, immunity, franchise, and privilege, which they had ever enjoyed;' and yet, immediately after, violating all of them as wantonly and perfidiously as ever. The sword of the lord mayor was at last ordered to be taken from him; and four of the aldermen were committed to different prisons, because they refused to be the instruments of exacting from their fellow-citizens a forced loan of £200,000. Submission had now reached its limits; and, in turning the sword of the city against the tyrant who demanded its surrender, the citizens did but their duty. The attempt, it is true, was far from ending in the attainment of that liberty and security for which the citizens took the field; for, after years of anarchy, they but exchanged one despotism for another—that of the king for that of the commonwealth; yet, though defrauded of the fair harvest which promised to crown their labours, the spirit is not the less to be commended which made them foremost in the fight when liberty seemed the prize. The destruction of the monarchy formed no part of the views which guided the more rational and respectable portion of the London citizens—they desired only to see it restored to a constitutional basis. When parliament passed the 'act for the eheredation of the royal line, and the abolition of monarchy in the kingdom,' Sir Abraham Reynardson, the lord mayor, refused to proclaim it in the city; and, for doing so, was degraded from his office, fined £2000, and committed to the tower.

The last to submit to the usurpation of Cromwell, the citizens of London were also the first to co-operate with Monk in his plans for the restoration of the exiled family. They made him the major-general of their forces, for the purpose of adding to his weight at this important crisis; and the lord mayor, Sir Thomas Adams, formed one of the deputation which went over to Breda, to invite the return of Charles II. The restored monarch evinced at first a just sense of the claims which the city had established to his kindness and protection. He granted them a charter, since called the Great Charter of Confirmation, in which all the privileges, liberties, rights, and customs, granted to the city by former sovereigns, were carefully recited, and now solemnly confirmed, 'in return for the late tokens of loyalty discovered in the said city

towards his person and government, by their effectual aid to restore him to the crown.' The gratitude of Charles, however, was but of brief duration. Neither the unhappy fall of his father, nor his own misfortunes, nor all the lights of the age, had been able to purify his nature from that love of arbitrary power which formed the hereditary vice of his race. Scarcely had the shouts which welcomed his return ceased to vibrate in the ear, when he entered on a similar career of misgovernment to that which had led his predecessor to the scaffold. Again were the citizens of London driven, by the course of events, to stand forward in defence of the rights of the subject; and, had the nation only supported them as well on this as they had done on former occasions, our history might have been spared the 'disgrace' which, in the opinion of an enlightened statesman, was cast on it by the impunity with which Charles II. was suffered to pursue his career of tyranny to its end.—Fox's Life of James II. When, in 1681, parliament was dissolved because of its refusal to proceed with the supplies till the bill for the exclusion of the duke of York from the throne, on account of his Catholic tenets, was passed, the citizens of London assembled in common hall, and, after voting thanks to their representatives for the share they had in this refusal, they resolved, 'by God's assistance, to stand by them with their lives and fortunes; being confidently assured, that the said members for the city will never consent to the granting any money or supply, till they have effectually secured them against popery and arbitrary power.' The same sentiments were echoed in the resolutions of other corporate bodies, in all parts of the country; yet when Charles, rather than accept of supplies on such terms, resolved to govern without a parliament at all, and became a pensionary to France for the means of supporting his state as an English monarch, no general effort was interposed to save the country from this declension into absolute despotism, and the citizens of London were left to be overwhelmed by the vengeance of the court, for the single example which it had presumed to offer of resistance to its will. 'The city of London,' says Mr. Fox, 'seemed to hold out for a certain time like a strong fortress in a conquered country; and, by means of this citadel, Shaftesbury and others were saved from the vengeance of the court. But this resistance, however honorable to the corporation who made it, could not be of long duration. The weapons of law and justice were found feeble when opposed to the power of a monarch, who was at the head of a numerous and bigoted party of the nation, and who, which was most material of all, had enabled himself to govern without parliament.' The court first succeeded in wresting from the livery of London, partly by corruption and partly by violence, the election of their mayor and sheriffs. As soon as it had thus obtained unlimited control over the administration of justice—the power of packing juries who would decide as they were ordered, and of nominating magistrates who would shrink from the execution of no iniquity—it began to maltreat and plunder, under color of law, all who had shown

themselves most forward in asserting the rights of the people. A fine of £1000 had hitherto been thought enormous; but such was the thirst of revenge which now animated the court party, that the fines imposed by venal judges, for what venal juries chose to pronounce offences against law, were increased to £10,000, £40,000, and even £100,000! Alderman Pilkington, and two other citizens, Colt and Oates, were fined £100,000 each, for speaking disrespectfully of the duke of York; Sir Patience Ward, who was lord mayor in 1681, was found guilty of perjury because he had sworn that he did not hear the words ascribed to Pilkington; nor could the just and mild principles which characterise the criminal law of England, protect even the lives of such men as Sidney, Russel, and Armstrong, 'when the sacrifice was called for by the policy and vengeance of the king.' Incredible as it may seem, something more was still wanted to complete the schemes of tyranny which the court was now triumphantly pursuing. It had got into its hands, as we have seen, the appointment of the mayor and sheriffs; but as the annual election to these offices, according to the chartered usages of the city, might, in some evil hour, give an opportunity to the disaffected to contest the power of nomination with success, it was decided to be necessary that the corporate privileges of the city should be abrogated entirely, and the government of it rendered simply and absolutely dependent on the king.—The citizens were served with a writ of quo warranto, calling upon them to show that they had not forfeited, by certain acts of malversation imputed to them, the various rights which the charters of a long line of sovereigns had conferred on them.

In the pretexts employed to obtain the cloak of a judicial decision, for this predetermined extinction of the corporation, a good deal of wicked ingenuity was displayed. When the crown, said the king's lawyers, conferred the privileges of a corporation on the citizens, they were of course intended to operate for the good of the crown; if employed for a different purpose, it was but right that they should revert to it; and that they had been so, was clear from the resolution which they had published after the dissolution of the parliament in 1681, to support, 'with their lives and fortunes,' the members who opposed the king. The charters of the city, moreover, had not conferred on it the right of taxing the lieges; and yet it had, of its own authority, imposed certain tolls on all goods brought thither for sale. The corporation had, in short, both scandalised the king's government and oppressed their fellow-subjects; and 'as the common council was the body of the city chosen by all the citizens, so they were all involved in what the common council did.' The council for the city had one invincible answer to make to all these arguments, namely, that whatever might be the character of the resistance which the corporation of 1681 had offered to the king, and however illegal the tolls which that or other corporations had imposed, yet they were but personal misdemeanours; and by the celebrated provision of Edward III. confirmed by every succeeding sovereign, it had been expressly declared, that 'the liberties of the city

could not be taken into the king's hands for any personal trespass or judgment of any minister of the said city.'

Defence, however, was unavailing, where judgment had previously been signed. In Trinity term, 1683, the court of king's bench declared it to be their opinion, that the malversations of the common council must be considered as acts of the whole city; and that the two points set forth in the pleadings of the crown were just grounds for the forfeiture of the city's charter. The attorney-general did not, however, enter up judgment immediately; in the hope, as it would seem, that, when the corporation saw their fate thus dependent on the nod of the king, they might be induced to come forward with some offer of compromise, by agreeing to which, the crown might probably gain more than it could hope to accomplish by the absolute resumption of the city's rights. The court party in the city, with a ready perception of what was expected from them, immediately called a court of common council, where they succeeded in procuring the adoption, by a considerable majority, of a petition to the king, in which the corporation fully acknowledged the misgovernment ascribed to them, solicited pardon, promised constant loyalty and obedience for the future, and placed themselves entirely at the disposal of his majesty.

The lord mayor, at the head of a numerous deputation from the council, presented this petition to the king. When Charles had read it, he handed it to the lord keeper North, desiring him to state the conditions on which his majesty would accede to the prayer of the petitioners. The conditions were—1. That no lord mayor, sheriff, recorder, common serjeant, town clerk, or coroner of the City of London, or steward of the borough of Southwark should be capable of, or admitted to, the exercise of their respective offices, before his majesty had approved them under his sign manual. 2. That if his majesty should disapprove the choice of any person to be lord mayor and signified the same under his sign manual, the citizens should, within one week, proceed to a new choice, and, if his majesty should also disapprove of the second choice, that he might himself nominate the lord mayor for the year ensuing. 4. That the lord mayor and court of aldermen might, with the leave of his majesty, displace any alderman or other officer of the city. 5. That on the election of an alderman, if the court of aldermen did not approve of him, the ward should be obliged to choose again; and, if the second choice was also disapproved, that the court might themselves fill up the vacancy. And 6. That all justices of the peace, within the bounds of the city, should be appointed by the king's commission; in other words, that no officer of the city should be ex-officio a justice. 'If these regulations are made,' continued the lord keeper, 'his majesty will not only stop this prosecution, but confirm your charters in all other respects. The term, my lord mayor, draws towards an end, and Midsummer is at hand, when some of the officers used to be chosen; whereof his majesty will reserve the approbation. It is, therefore, his majesty's pleasure that you return

to the city, and convene the common council, that he may speedily know your resolutions thereupon, and give his directions accordingly. That you may see the king is in earnest, and the matter is not capable of delay, I am commanded to let you know, that his majesty has given orders to his attorney-general to enter up judgment on Saturday next, unless you prevent it by your compliance in all these particulars.'

On the return of the deputation to the city, a court of common council was immediately summoned to consider of the king's propositions. The debates which it produced were warm and tempestuous. Numbers there still were devotedly attached to liberty, who declared, that they would rather sacrifice all that was dear to them, than consent to such slavish conditions. 'If we must,' said they, 'sink under oppression; let us at least have the consolation left us, that it was by no act of our own that we lost our birthright; that we became slaves not through choice, but by force.' Other sentiments, unhappily, prevailed with a larger party of the council; and the degradation of the city was consummated, by the consent of a majority of eighteen, to all that the king required. Charles appears, however, to have disdained the triumph he had achieved; for to the surprise and mortification of the servile crowd, who had thus proclaimed themselves his willing slaves, he refused to set his seal to the arrangement, and preferred entering up the judgment which had been pronounced on the *quo warranto*. It has been generally supposed, that he followed this course from a wish to heap degradation and insult on the city; but the inference is superficial and improbable. Charles had no cause to be displeased with his own friends and partizans—with the majority who voted for submission to his terms—and it was on them alone all the ignominy of such treatment fell; while, to those who opposed concession, it must have been a source of just pride to witness the shame and confusion of its advocates. The circumstance which in all probability determined the conduct of Charles, was the smallness of the majority by which the acceptance of his propositions was carried; for, while so numerous a party remained hostile to the pretensions of the crown, any attempt to conduct the government of the city, through the medium of the citizens themselves, must have been attended with perpetual embarrassment, and not altogether exempt from the chance of utter failure.

The judgment on the *quo warranto* having been entered up, the king, by a commission under the great seal, appointed the creatures of the crown who then filled the offices of mayor and sheriffs, to hold the same during pleasure; and nominated another individual of the same cast to the recorder, in place of Sir George Treby, who, as counsel for the city, had advocated its privileges with honesty and zeal. The fate of London spread a general alarm among the corporations throughout the country; and in the vain hope of escaping the general sweep which they supposed to be meditated, by a spontaneous submission to the will of the king, most of them resigned their charters into his hands, with a request rather slightly expressed, that his majesty

would be pleased to re-model them in such manner as he might in his wisdom think meet. The king accepted the surrenders; but, in all the new charters which he gave, reserved to the crown the nomination to every place of power and profit, and for the few indifferent privileges which they contained, exacted large sums.

The duke of York, by whose advice the gay and dissolute Charles chiefly acted in these oppressive measures, at length succeeded him in the throne; and being now enabled to give full scope to his inclinations, he speedily filled up that measure of iniquity which led so deservedly to his own downfall, and to the final expulsion of his house. One of the earliest victims of the tyranny of James II. was alderman Cornish, who, in discharging his official duties, when Sheriff, in 1680, had particularly exerted himself in the detection and prosecution of what was called the Popish plot, the reality of which, his majesty, with a view to the introduction of popery, was now using every possible endeavour to discredit. Cornish was now accused of being concerned in the Ryehouse plot, for which lord William Russel suffered, and on suborned testimony, to which no man gave serious credit, was found, by a packed jury, guilty of high treason. That the vengeance inflicted on this ill-fated gentleman might inspire the greater terror in the community, the merciless Jefferies ordered that he should be hanged, drawn, and quartered, not at the usual place of execution, but in front of his own door, at the end of King Street, Cheapside. On the 23d of October, 1685, the citizens beheld with horror and dismay this barbarous sentence literally carried into execution. James had no sooner glutted his monstrous revenge, than conscience appears to have begun her upbraidings. In the memoirs of his life, which Dr. Clarke has compiled from James's own papers, we read that 'although Cornish had been a furious stickler in these times, and that no one doubted his guilt, yet when his majesty heard that one of the witnesses against him did not so positively reach to what is criminal in the case, he was troubled that the least formality in the law should have been infringed for his security, and therefore declared he was sorry he had suffered, and (marvellous compassion!) ordered his quarters to be taken down, and given to his relations to be decently buried.' *Life of James*, vol. 1. p. 45. Never, perhaps, were guilt, confusion, and shame more apparent than in these few lines. At first, we are told 'no one doubted his guilt,' and next, that his majesty had 'heard that one of the witnesses (as there were but two, the failure of the one destroyed the whole case), did not so positively reach to what was criminal in the case.' And so for want of this slight 'formality,' the mere want of evidence that he had done any thing 'criminal,' any thing meriting punishment at all, far less a fate so cruelly aggravated as that which befel him, is the conscience of the tyrant 'troubled!' A succeeding age did more justice to the real character of this transaction, when it pronounced the execution of Alderman Cornish to be among the most odious cruelties of James's reign, restored his estate to his family (for, with all his compassion, James

scrupled not to beggar the children whom his cruelties had made fatherless); and condemned the witnesses against him to be lodged in remote prisons for the remainder of their lives.

When at length the nation rose, as one man, to expel their oppressor, James became as mean and pitiful in his concessions, as he had been proud and arrogant in his usurpations. Among other steps which he took to avert the impending ruin, he directed that intimation should be made to the lord mayor and aldermen of the city that he had resolved 'out of 'tender regard' merely) to restore to them, by a new charter, all the ancient franchises and privileges on which they had been deprived by the decision of the quo warranto. He sent at the same time for Mr. William Kyffin, a merchant of great weight and eminence in the city, who still mourned the loss of two grandsons, who had been executed for the rebellion in the West, with circumstances of peculiar cruelty; and in the hope of conciliating him, by such honors as it was yet in his power to bestow, told him, that 'he had put down his name as an alderman in the new charter.' 'Sir,' answered Kyffin, 'I am a very old man; I have withdrawn myself from all kind of business for some years past, and am incapable of doing any service, in such an affair, to your majesty or the city.—Besides, sir,' continued the old man, fixing his eyes stedfastly on the king, while the tears ran down his cheeks, 'the death of my grandsons gave a wound to my heart which is still bleeding, and never will close but in the grave.'—(Hughes's Letters.)—O bitter reproach! O most just retribution! Not even the name of this venerated sufferer, however, nor the names of all the city sufferers from James's tyranny together, could have sufficed to obtain respect for a charter thus meanly tendered in the hour of desperation. The time for reconciliation and compromise had for ever passed. The citizens of London—the whole nation—saw safety only in revolution; James was forced to abdicate the throne which he had disgraced, without a single arm being raised in his defence; and the vacant diadem was transferred to the Prince of Orange and his consort, on terms by which liberty and happiness were once more restored to the country; and the relative rights of sovereign and subject placed on a surer and more lasting basis than they had ever yet been.

One of the first acts of the first parliament of William the third, was to do justice to the city of London. The judgment given on the quo warranto, by this was pronounced to be illegal and arbitrary; every right, charter, and indemnity, anciently conferred on the city, was restored; and all grants prejudicial to them, which had been made by the two last sovereigns, were declared null and void. 'Glorious,' indeed, this revolution deserves to be called by the citizens of London. Nearly a century and a half have since elapsed, and during all this period they have as freely enjoyed as they have spiritedly maintained their municipal privileges.

The citizens were not insensible to the benefits thus gained, and lost no opportunity of showing how ready they were to support a government founded on the principles of liberty. William

having suppressed the rebellion in Ireland, and consolidated his government at home, resolved, in 1691, to pay a visit to his Dutch dominions, leaving his illustrious and amiable consort, queen Mary, regent. Scarcely had his majesty quitted the British shores, however, when a report was raised by the jacobite faction, that the French were on the point of invading England with a large force, in order to restore the exiled James. No circumstance could have been more fortunate for the house of Orange, since it proved its stability on the throne; for the threats of invasion excited no alarm, but much preparation. The city of London increased its military force, and, well knowing that money was the sinew of war, the common council voted an advance of £200,000 to the queen.

So much had the city suffered from a popish monarch, that the strongest prejudices existed at this time against the Roman Catholics, so that in the years 1697, 1699, and 1700, proclamations were issued, fixing their residence within certain limits, and empowering the magistracy to seize all arms and ammunition found in their possession. But no attempts were made in London to disturb the public tranquillity, although the violence of party was often manifested in a strong degree. An instance of this occurred in 1710, when the intemperate Dr. Sacheverell attempted to revive the principles which had been the cause of hurling the Stuarts from the throne. The Dr. preached two sermons, in which he censured the act of toleration, and vindicated the doctrine of non-resistance to the government to the utmost extent. The house of commons took up this business, and after declaring his sermons to be 'malicious, scandalous, and seditious libels,' appointed a committee to draw up articles of impeachment against him. The house of lords, however, thought the matter had been treated too seriously, and, although they condemned Sacheverell by a majority of seventeen voices, he was merely restrained from preaching for three years. During these proceedings the Dr., who was of the high church party, became a great favorite with a considerable portion of the populace of London, who considered him as the champion of the established church, and suffering for its sake. They conducted him in triumph from Westminster Hall to his house, and testified their zeal in his cause, by attacking the dissenting meeting-houses, particularly the chapel of the eccentric Daniel Burgess, in New Court, Carey Street. They tore down the pulpit, the pews, and benches, and made a fire of them in Lincoln's-Inn-fields.

The accession of the house of Brunswick to the throne was hailed in the metropolis and through Great Britain as the last act of the great drama of the revolution; for, although queen Anne was popular, it was known that in her latter days she wavered as to her successor, and, could she have possessed sufficient power to influence the appointment, it was believed she would have recalled a member of her own family. No sooner had George I. arrived than he received the warm congratulations of the city, and in his answer to their address complimented them on their importance, and assured them that he

would take their privileges and interests under his particular protection. On the ensuing lord mayor's day, the king and the royal family dined in the city; on which occasion he created the lord mayor, Sir William Humphreys, a baronet, and gave £1000 to be applied for the relief and discharge of poor people imprisoned for debt.

The rebellion of 1715 excited some sensation in the metropolis, but did not in the slightest degree affect the citizens, who, in an address to his majesty, declared their unalterable adherence to the royal person and government. In 1721 the plague raged so furiously at Marseilles, that strong measures were taken by the legislature to prevent its being introduced into this country. One of the clauses in the law enacted, that 'every infected place should be enclosed and shut up by a line or trench, in order to cut off all communication, and that all persons endeavouring to escape from the said infected place, without having regularly performed quarantine, should suffer death as felons, without benefit of clergy.' The corporation of the city, ever watchful of the privileges of their fellow citizens, presented a petition against this bill; and, although unsuccessful in the first instance, they procured its repeal in the following year. Nor was it to matters of a local nature that the city limited its interference, wisely considering every infringement on the liberties of any class of individuals, as an attack on the liberties of all.

With this feeling, in the year 1733, the court of common council resisted the extension of the excise laws, by Sir Robert Walpole. On the day fixed by the minister to propose the obnoxious measure, the citizens in great numbers thronged the avenues leading to the house of commons, when Sir Robert, with an indiscretion not usual with him, insinuated that the multitude who had assembled had been gathered together unfairly, and applied to them the legal term of 'sturdy beggars.' The patriotic Sir John Barnard, at that time one of the members for the city, resented with becoming spirit this attack of the minister. 'The right honorable gentleman,' he said, 'talks of sturdy beggars: I do not know what sort of people, Mr. Speaker, may now be at your door, because I have not been lately out of the house, but I believe they are the same sort of people that were there when I entered the house; and then, sir, I can assure you, that I saw none but such as deserve the name of sturdy beggars as little as the right honorable gentleman himself, or any gentleman whatever.' When, finally, the sheriffs, who were accompanied by the chief citizens in 200 carriages, presented the petition of the lord mayor, aldermen, and common-council, against the bill, at the bar of the house; the minister took the alarm, and, perceiving the unpopularity of the measure, abandoned it.

In the rebellion of 1745 the city of London again exhibited its firm attachment to the protestant succession. Addresses were presented by the corporation, and by the merchants of the metropolis, who proceeded, in 140 coaches, to declare their fidelity to the throne. The military preparations were prompt and vigorous; and when the duke of Cumberland, after putting

down the rebellion, returned to London, he was presented with the freedom of the city in a gold box.

Ready, however, as the citizens were, at all times, to support the government, and to sanction every measure consistent with the honor and interests of the country, they never ceased to watch over their own liberties. A proof of their vigilance in this respect occurred in the year 1749, when the government suspecting that an attempt would be made to rescue two men, who had been principals in a riot in the Strand, ordered a party of the foot-guards to attend at Holborn Bars, and assist the civil authorities in guarding the prisoners to Tyburn. The sheriff, Mr. Janssen, knowing that the constitution and usages of the city precluded the interference of the military, civilly dismissed the guard, and, heading his own body of police, secured the due execution of the law without molestation.

The early part of the reign of George III. was agitated by the well-known proceedings against Wilkes, who was committed to the tower on a warrant (afterwards declared to be illegal) from the secretary of state, for a libel in No. XLV. of the North Briton. On being liberated, by the decision of lord chief justice Pratt in his favor, Mr. Wilkes brought an action against the under secretary for illegally seizing his papers, and obtained £1000 damages. He afterwards reprinted the obnoxious No. of the North Briton, when the house of commons expelled him, and a prosecution was commenced against him in the court of king's bench, in which the publication was adjudged a libel, and, on his not appearing to receive sentence, he was outlawed. The public now manifested a strong feeling in favor of this demagogue; and, when the house of commons ordered the libellous number of the North Briton to be burnt by the common hangman, the populace assailed the sheriff and city officers, who attempted to carry the order into effect at the Royal Exchange, and broke the glass of sheriff Harley's carriage. They also snatched the libel from the flames, and proceeded to Temple Bar, where they made a bonfire, into which they threw a large jack boot, in allusion to lord Bute, then prime minister.

In 1768 Wilkes, who had retired to France, suddenly made his appearance on the hustings at Guildhall, at the general election, and offered himself as a candidate to represent the city; failing in this object, he determined to stand for the county of Middlesex, and was elected by a large majority; when his partizans, not having the discretion to enjoy their triumph in quiet, committed several outrages. Mr. Wilkes had been committed to the king's bench prison, on a sentence against him for the libel. On the 10th of May, when the parliament met, an opinion prevailed that he could not be detained, and a great concourse of people assembled, ready to convey him in triumph to the house of commons; but finding there was no prospect of his liberation they became very clamorous. This alarmed the Surry magistrates, who called in the aid of the military and read the riot act. The mob, incensed at what they deemed an unnecessary interference, assailed the soldiers with stones and brick-bats; when the latter, who were principally

Scotchmen, became irritated, and one of them, wantonly discharging his musket, shot Mr. Allen, the son of a livery stable keeper, at the door of his father's cow-house. The soldiers were afterwards ordered to fire, and upwards of twenty persons were killed and wounded.

The death of Allen, who had not participated in the riot, excited a great sensation, not only in the metropolis, but in 'the country; and the celebrated Horne Tooke strained every nerve to bring the offender to justice, but without effect.

The house of commons, as we have seen (article GREAT BRITAIN) now annulled Wilkes's election, and the Middlesex freeholders, twice in the course of six weeks, re-elected him. A third writ was issued, when colonel Luttrell was induced to offer himself; and although his rival was again returned, by a majority of 850 votes, the house of commons declared the colonel the sitting member. Petitions were presented from the city of London, as well as from the inhabitants of the county, against these proceedings, but without effect, until the great question as to the legality of general warrants was decided in the court of common pleas, in November 1769, by Wilkes obtaining a verdict of £4000 against the earl of Halifax then secretary of state. In the month of April following, the former who had previously been elected alderman of the city was liberated; on which occasion the metropolis was illuminated. His triumph was not yet, however, complete, and it was not until after a long struggle that the legality of his seat in the house of commons was admitted, and the proceedings against him ordered to be erased from the journals.

The tumults of this period of the history of London were not always of a political nature: the Spitalfields weavers, who felt aggrieved by the introduction of foreign manufactures and the low rate of wages, had long exhibited symptoms of discontent, and on more than one occasion been guilty of excesses. Towards the close of the year 1769 these proceedings became more serious, and a party of the guards was called in to seize some of the ringleaders, at the Dolphin public-house. On entering the house, the weavers, who were armed, attacked the soldiers, one of whom they killed; the soldiers returned the fire, killed two of the rioters, and took four others prisoners. Two of these were capitally convicted; and government deeming it necessary to display its rigor, in order to deter future offenders, by an exemplary punishment, ordered them to be executed near Bethnal Green church. The sheriffs, doubting how far they were authorised to deviate from the sentence pronounced in the Old Bailey, sent several memorials to the minister, and the convicts were respited until the opinion of the judges could be taken on the subject, when, they having declared, that 'the time and place of execution are in law no part of the judgment, and that the recorder's warrant was a lawful authority to the sheriffs as to the time and place of execution,' the criminals were executed at the place fixed upon by the government.

Two other events occurred at this period, which strongly marked the watchfulness of the city magistrates in preserving the liberties of the

citizens. During the riots in Spitalfields, the soldiers had passed through the city unmolested, until the commanding officer on one occasion marched his men to the sound of the drum and fife through all the public streets. The patriotic Beckford, then lord mayor, immediately wrote to lord Barrington, the secretary of state, to request an explanation, which was promptly and satisfactorily given. 'I am very clear in opinion,' said his lordship, 'that no troops should march through the city of London, in the manner described by your lordship, without previous notice given to the lord mayor.' His lordship added, that he would take such measures as he trusted for the future would 'prevent any just offence being given to the city or its chief magistrate.' In later times, however, the city has become less scrupulous in this respect, though the right to exclude the military remains undisputed.

In 1771 the city made a strong effort to oppose the authority of the house of commons in cases of breach of privilege. Messrs. Wheble and Miller, the printers of two newspapers, had been ordered to the bar of the house, on a charge of having violated its privileges, by the publication of reports of parliamentary proceedings. The serjeant at arms failing in taking them into custody, a royal proclamation was issued, offering a reward for their apprehension. Mr. Wheble was then taken by a journeyman printer, and brought before Mr. Wilkes, the sitting alderman at Guildhall, who, not recognising the authority of the proclamation, discharged Wheble, having first bound him over to prosecute the man who had arrested him. Mr. Miller was arrested at his own house, by a messenger from the house of commons; but he gave him in charge to a constable, and had him carried to the mansion-house, where the lord mayor, Brass Crosby, esq., and the aldermen Wilkes and Oliver were sitting. The serjeant at arms attended, and in the name of the house of commons demanded Miller and the messenger. The lord mayor refused on the ground that the warrant was illegal, not having been indorsed by a city magistrate, and ordered the messenger to enter into recognisances to answer the assault at the next sessions in Guildhall. The house of commons, indignant that the city should thus beard its authority, ordered the lord mayor and the two aldermen to appear before them. Wilkes refused to attend, unless he was summoned as member for Middlesex; but the commons, not having acknowledged the legality of his election, would not do this, and, in order to avoid any farther contest with a man who had so often foiled them, adjourned over the day fixed for his appearance. The aldermen Crosby and Oliver appeared to the order of the house, and were committed to the tower, where they remained until the prorogation of parliament.

The citizens, however, so far approved of the conduct of their magistrates, that a committee was appointed to procure their liberation by an appeal to the courts of law, but the judges refused to interfere with the privileges of the house of commons. On their liberation, they were saluted at the Tower gate by a salute of twenty-one guns, and were escorted to the Mansion House by the artill-

lery company and several of the most eminent citizens in fifty-three coaches. Silver cups were voted by the common council and livery to these public spirited magistrates; and the printer who had arrested Mr. Wheble was tried at Guildhall for the assault, when he was sentenced to two month's imprisonment in the compter, and to pay a fine of one shilling.

In a subsequent year the city made a formidable opposition to the obnoxious system of impressment, but the decision of lord Mansfield was not in their favor, although his lordship vindicated the measure rather on the principle of necessity than of law.

It is to be regretted, that, while the city magistracy manifested such watchful jealousy of their liberties, a party of misguided men should be guilty of such acts of intolerance and outrage as disgraced the metropolis in the year 1780. We refer for the details of them to our article **GREAT BRITAIN**. Dr. Johnson, in his Letters to Mrs. Thrale, when giving what he calls a journal of 'a week's defiance of government,' unhesitatingly states that if the mob had attacked the bank 'at the height of the panic,' on Tuesday instead of the Wednesday night, 'when no resistance had been prepared, they might have carried irrecoverably away whatever they had found.' Wilkes headed the party who drove the rioters away, and this was the first effectual resistance they encountered.

Certainly the ministers had become so obnoxious, that scarcely any measure that originated with them could give satisfaction. War is seldom unpopular while it is successful, but the contest with the colonies in America was not only considered as impolitic, but the ill success which attended it generated a mass of discontent in the metropolis, which manifested itself on all occasions. Strong remonstrances were presented to his majesty from the city in 1781, deprecating all further perseverance in 'a system of measures which had proved so disastrous to the country,' and intreating him to dismiss, from his presence and councils, all those persons who had deluded him into an 'unfortunate and unnatural war.' It has been the maxim of the citizens to speak their sentiments boldly, and to bear to the throne their grievances, but they have still always been foremost in loyalty to the sovereign, and in support of the government when it required their aid.

Many opportunities have occurred in which they have manifested both. When, in the year 1786, the wretched maniac Margaret Nicholson, attempted to stab our late venerated sovereign, the citizens of London were the first to express their congratulations on his majesty's escape; and three years afterwards, when the king had recovered from the dreadful malady with which he had been afflicted, the metropolis was one scene of gaiety and joy; when the first moments of exultation had subsided, they crowded to the altar, and joined their majesties in returning thanks to that Being who has the hearts of kings in his keeping, and who chasteneth those whom he loveth.

The early appearances of the French revolution were hailed with transport in a country

which had long been considered as the natural and political enemy of France; but as, in times of political effervescence, some ardent minds will overstep the bounds of discretion, it was not to be surprised that a portion, even of the population of London should sigh for institution: they had been led to believe more liberal than their own. Political associations were formed, which, at a less critical moment, would have excited no alarm; and individuals were prosecuted, whose plans might have been sufficiently watched and defeated by a vigilant police, yet it is difficult to censure the government even for an unnecessary vigor in preserving the country from the horrors of a revolution. The prosecution of Tooke, Hardy, Thelwall, and Bonney, in 1794, on a charge of high treason, was, perhaps, ill-advised, though the result proved a triumph to civil liberty; for it was on this trial that the doctrine of constructive treason, which, in a darker period of our history had sent many to the block, was overturned by the eloquence of an Erskine and a Gibbs. A less exceptionable mode of counteracting the spread of sedition was afterwards adopted by the formation of loyal associations. The dread of an insurrection in this country, when the scenes, which had been acted in Paris, might be re-acted in the British metropolis, now excited alarm, and a meeting was held at Merchant Tailors' Hall, of 3000 of the principal merchants, bankers, and traders of the capital, who agreed to a declaration of attachment to the constitution, which, in a few days, was signed by upwards of 8000 individuals, the most respectable for rank, character, and property.

But nothing tended so much to heal the political dissensions which, at this period, distracted the country as well as the metropolis, as the war which commenced between this country and France. The court of common council now addressed his majesty, to thank him 'for his paternal care in the preservation of the public tranquillity,' and assured him of 'the readiness and determination of his faithful citizens to support the honor of his crown, and the welfare of his kingdoms, against the ambitious designs of France.'

A few tumults, but not of a political nature, occurred about this time, in which some crimping houses, and decoy houses for recruiting, were destroyed by the mob: the pop-gun plot, in which three persons were apprehended for a conspiracy to assassinate the king, also excited some alarm, but, after the persons had been confined a few months, they were liberated; not but that there were individuals capable of committing the most daring outrages, even on their sovereign, who, in proceeding to open the parliament, in October, 1795, was beset by a mob, said to amount to 100,000 persons: they assailed his majesty with seditious cries; several stones were also thrown at the royal carriage, and one of the glass pannels was broken by a bullet either of lead or marble.

While a misguided populace were thus insulting one of the best of monarchs, the monied interest of London was manifesting the strongest marks of confidence in his majesty's conduct. The

exigencies of the times requiring extraordinary supplies, Mr. Pitt, who calculated largely, but not erroneously, on the disposition of the city, proposed raising a voluntary loan of £18,000,000, and on the 1st of December, 1796, communicated his project to the lord mayor, requesting him to make it known to the corporation and public companies. Had the minister offered to lend the sum, instead of asking to borrow it, he could not have been answered more promptly. The bank lent £1,000,000, and in four days the whole sum was subscribed, so that when the court of common council voted £100,000, on the morning of the fifth day, it was only admitted as a favor. Two years afterwards the merchants, bankers, and traders of London determined on aiding government with a voluntary subscription, which, in the course of a few hours on the day it was proposed in the Royal Exchange, amounted to £46,500; the bank added £200,000, and the court of common council £10,000; and, in the course of a very short time, the subscription amounted to nearly £2,000,000.

The vigor with which the war was prosecuted, the patience with which the people submitted to every privation, and the joy with which peace was hailed, are events which belong to the history of Great Britain, and not to London in particular. The peace was, however, of short duration, and the government found the people ready for new sacrifices.

The domestic history of this period was marked by a conspiracy to overturn the constitution, when colonel Despard, and other persons of the lower class of society, were arrested at a public-house—the Oakley Arms, Oakley Street. In the month of February, 1803, ten of them were convicted of high-treason, and on the 21st of that month Despard and six others were executed on the top of Horsemonger gaol, Southwark; their heads were cut off and exhibited to the crowd, but the other part of the sentence on traitors was remitted.

During the long war that ensued, party politics were carried to a great length, not only in the senate, but also in the city council, and on more than one occasion the citizens were divided in their sentiments, as to the measures of government: a new call for men or money, or a new opportunity of testifying their loyalty, was however sure to unite all ranks and parties, and no loyalty could be less equivocal than that which was manifested in the metropolis on the 25th of October, 1809, when his late majesty entered the fiftieth year of his reign, and which was celebrated as a jubilee. The arms of France had triumphed over every continental power, and England, left to continue the struggle single-handed, had swept the ocean of her enemies, and sighed for new worlds to conquer—or a new stage on which to renew the combat, when the Spaniards began to shake off the lethargy which had placed them beneath the yoke of the Gallic emperor. England was not backward in her aid, and the city of London, equally prompt, opened the subscription for the Spanish army, which, in the course of a few weeks, amounted to upwards of £50,000. The contest was obstinate, and the issue long doubtful, when a domes-

tic event created an alarming sensation in the metropolis. On the evening of the 11th of May, 1812, as Mr. Percival, the chancellor of the exchequer, was entering the lobby of the house of commons, he was shot by a person of the name of John Bellingham. In the first moment of alarm it was feared that this sanguinary act might only be part of a deep laid and extensive conspiracy against government, but it was soon discovered that it was the single act of an assassin, who had become desperate by misfortune, and imagined that government had not afforded him the protection to which he was entitled in his commercial intercourse with Russia. The wretched man, who made no attempt to escape, was taken into custody, tried and convicted at the Old Bailey, on the Friday morning, and on Monday the 18th he was executed.

From the time that his present majesty was appointed regent, in January 1811, in consequence of the malady with which his royal sire was afflicted, the success of the British arms became as signal on land as it hitherto had been at sea; and often were the tranquil pursuits of the citizens interrupted by the roar of the park and tower guns, announcing some new victory obtained by our gallant troops in the Peninsula under the illustrious Wellington, until even victory lost its novelty; and the people of England felt more joy in giving peace to France than they had done in all their triumphs over her.

The treaty concluded at Paris, on the 30th of May 1814, gave peace to Europe, after a war of more than twenty years' duration; and, on the 8th of the following month, the emperor of Russia, the king of Prussia, and two of his sons, with several of the Austrian, Russian, and Prussian generals who had most distinguished themselves, visited London, and were treated by the court and the city with true English hospitality.

The war which had been for some time carried on between Great Britain and the United States of America, was terminated by the treaty of Ghent; but scarcely had the nation felt the blessings of peace, when Napoleon, the emperor of France, who, on his abdication, had chosen and been allowed the Isle of Elba for his residence, returned to France, and, in a march to Paris which has no parallel in history, overturned the government of the Bourbons, and reseatd himself on the imperial throne, without drawing a sword, or firing a musket. The clangor of arms again resounded through Europe. The British troops, under the command of the duke of Wellington were cantoned in the Netherlands, and the Prussians soon marched to their support. The battle of Waterloo followed—the anxiety in London for tidings of its results was unbounded; we need not repeat what they were: the allied armies again entered Paris; Buonaparte surrendered himself to the British nation, and was sent to the Island of St. Helena, where the imperial exile died on the 5th of May 1821.

Domestic calamities and domestic dissensions succeeded the war; the princess Charlotte of Wales, who had been married to prince Leopold of Saxe Coburg, in the preceding year, died on the 6th of November, 1817, in child-bed, to the great grief of the whole nation! and never per-

naps did the metropolis wear an aspect of such profound and sincere grief as on the day of her funeral: all business was suspended, and the churches and chapels were unable to contain the numbers that crowded to acknowledge their submission to the will of the divine Being.

Some time previous to this period several meetings had taken place in Spa-fields, and other places, for the avowed purpose of petitioning or remonstrating with the government. One of these was held on the 2d of December 1816, and was followed by riots in the city. Some pawn-brokers' and gunsmiths' shops were robbed, and several outrages committed. Four persons were arrested for high-treason, and tried, but were acquitted. One of the rioters was, however, convicted and executed.

The metropolis was still in an unsettled state, and in January 1818 it was deemed necessary to suspend the Habeas Corpus Act, which for some time restrained the disaffected; until the Cato Street conspiracy was discovered in 1820, when nine persons were secured in a small stable-loft, where they had assembled on the night fixed upon for assassinating his majesty's ministers, while assembled at dinner at the house of lord Harrowby. The ring-leader Thistlewood, who had been tried for high treason in 1817, at first escaped, but was taken next day, and, together with five of his associates, tried and executed at the Old Bailey, 29th of April. Since this occurrence the tranquillity of the metropolis has been undisturbed by any political events of moment.

REMARKABLE DISTINCT EVENTS.

There are some few events in the history of London so remarkably distinct from the general occurrences of our narrative, that we have thought they would prove more acceptable to our readers as separate addenda.

1. *Earthquakes and hurricanes*, as natural calamities, first demand our attention. London has been but four times visited with any shocks of the former kind, and they have been remarkably slight. The first of them known in history occurred on Valentine's Eve, in the year 1247, but the damage done was trifling; as was that of two others in 1601 and 1692; a severer shock was experienced in 1580, when Stowe assures us several churches were shattered, and the bells struck against the hammers. Two other shocks were felt on the 8th of February and 8th of March, 1751, which the fears of the inhabitants appear to have magnified excessively—for the only damage that they did was what is done by a high wind every year, throwing down a few chimneys and some old houses, which ought to have been condemned. The earthquake of 1751 afforded one Bell, a life-guards-man, the opportunity to practise on the credulity of the people, by prophesying, that 'as the second earthquake had happened exactly four weeks after the first, so there would be a third precisely four weeks after the second, which would lay the cities of London and Westminster in ruins.' So great was the panic, that, a few days before the threatened destruction, the inhabitants began to quit the town in great numbers. 'Many persons,' say the newspapers of the day 'left their houses

and walked in the fields, or lay in boats all night, many people of fashion in the neighbouring villages sat in their coaches till day break; others went to a greater distance, so that the roads were never more thronged, and lodgings were hardly to be procured at Windsor; so far, and even to their wit's end, had their superstitious fears, or their guilty consciences, driven them.'

But this metropolis has frequently and severely suffered by hurricanes: on one occasion more severely than by any other calamity, except by the great fire. The most remarkable storms have been those of the years 1440, 1445, 1599, 1703, 1739, 1740, 1788, 1790, 1794, 1797, 1798, and 1801; but, with the exception of that of 1703, none of these were very destructive. The last mentioned hurricane, which is often denominated the high wind of 1703, began about ten o'clock on the night of the 16th of November, and raged with unabated fury until seven o'clock next morning. Such a scene of devastation was scarcely ever witnessed as in a few hours had been committed in London, where 2000 stacks of chimneys were blown down, and the lead torn from the roofs of several churches, or rolled up like skins of parchment. Two turrets, which had been built a short time before on the church of St. Mary, Aldermary, the four pinnacles of St. Michael's in Cornhill, and one of the spires of St. Saviour's, Southwark, were blown down; the guard room, at Whitehall, was completely unroofed; the vanes and spindles of the weather-cocks on nearly all the churches were broken to pieces; upwards of thirty houses in Moorfields and other parts of the town were entirely blown down, and several hundreds more were dilapidated. Twenty-one persons were killed, and upwards of 200 severely wounded by the falling of chimneys and houses. All the ships in the river Thames, except four, broke from their moorings, and were cast on shore, principally between Shadwell and Limehouse; sixty barges were driven, with great fury, against London-bridge, many of which were sunk or staved, and nearly 500 wherries were entirely lost. The loss sustained in London was estimated at £2,000,000 sterling, and such was the demand for tiles for covering the dilapidated houses, that the price was advanced from £1 1s. to £6 6s. per 1000, and bricklayers' labor rose in an equal proportion. It was in this storm that the Eddystone light-house was blown down.

2. *Remarkable fires*.—The first fire in London we find noticed is by the Iceni under Boadicea, who laid Colchester, St. Albans, and London, waste by fire and the sword. In the years 764, 798, and 801, also, London suffered severely from conflagration, particularly in 798, when the city was almost burnt down, and many of the inhabitants perished in the flames. In 982 a fire accidentally took place, which nearly destroyed the whole city; but, according to the Saxon chronicle, 'the greatest casual fire that till this time befel the city' was in 1077, 'when the greatest part of it was laid in ashes.'

We find, however, the city rebuilt, and a prey to a still greater fire in the year 1086, which Stowe says, 'spread over almost all the principal cities of England: the church of St. Paul's, in London, was burnt, with the most part of the

city, which fire began at the entry of the west gate, and consumed to the east gate.' Another fire in 1090 destroyed a considerable part of the city; which in 1135 again fell a prey to the flames. This began near London Stone, and burnt eastward as far as Aldgate, and westward to St. Paul's. The fire of 1212 belongs rather to the account of London Bridge. See our Part III. of this article. In 1232 and 1483 London was visited with fires; in the latter, which began at Leadenhall, Stowe says, 'much housing was burnt, and all the stocks for guns, and other like provision, belonging to the city.'

The great fire of London, as it has been most appropriately called, broke out at one o'clock on Sunday morning Sept. 2d, 1666, at the house of one Farryner, a baker, in Pudding Lane, Fish Street Hill. Whether it originated in accident or design is a point on which historians by no means agree, while all concur in representing it as at once more destructive in its progress, and ultimately productive of more beneficial effects, than any conflagration recorded in history. It is even the opinion of more than one respectable writer, that the fire was almost necessary to promote the complete extinction of the plague, which had the year before dealt desolation with such an unsparing hand in the metropolis, that the very air had become tainted with the putrefaction of the dead; we are far from thinking this to have been the case, but it is not too much to infer, that, had it not been for some such calamity as the great fire, London might long have suffered by that dreadful scourge of humanity, which its crowded streets, by confining the circulation of the air, and the want of cleanliness on account of the scanty supply of water, seemed so well calculated to promote. It is true that a city was destroyed and property to an unparalleled amount was lost; but the result was, a new city, improved in wealth, grandeur, and all the conveniences of life, which otherwise would not have been obtained for ages: and, however fatal the calamity must have been to the age in which it happened, it has been productive of the most lasting benefits to posterity. The part of the town where it began is now very confined, but it was much more so at that time, when the neighbourhood consisted of nothing but narrow lanes and passages, and the houses were principally of wood, or lath and plaster. The fire soon spread to the adjacent houses, and defied the power of buckets, for the engines could not be brought to bear upon it with any degree of success, on account of the narrowness of the streets. It was then suggested to the lord mayor, Sir Thomas Bludworth, who arrived on the spot at three o'clock in the morning, that it would be advisable to pull down several houses, in order to intercept the progress of the flames; but he refused to allow of so prudent a measure, and is said to have expressed his opinion of the insignificance of the fire in flippant and indelicate terms. By eight o'clock in the morning it had reached London Bridge, 'and there dividing, left enough to burn down all that had been erected on it since the fire in 1633, and, with the main body pressed forward into Thames Street,' which was charged with combustible materials that augmented it

very considerably, raging with great fury the whole day, and striking the inhabitants with such terror, that, says Lord Clarendon, 'all men stood amazed as spectators only, no man knowing what remedy to apply, nor the magistrates what orders to give.'

The amiable Evelyn, who has left a most nervous and unaffected narrative of this great calamity, says, 'the conflagration was so universal, and the people so astonished, that from the beginning, I know not by what despondency or fate, they hardly stirred to quench it, so that there was nothing heard or seen but crying out and lamentations, running about like distracted creatures, without at all attempting to save even their goods, such a strange consternation there was upon them.' At first the fire took an easterly direction, and proceeded so rapidly, that considerable fears were entertained it would reach the tower, to prevent which several houses were pulled down: but on the night of Monday it became directed to other quarters. The wind changed, and blew with 'so great and irresistible violence, that it scattered the fire from pursuing the line that it was in with all its force, and spread it over the city, so that they who went late to bed, at a great distance from any place where the fire prevailed, were awakened before morning with their own houses being in a flame.' On Monday, Gracechurch Street, and part of both Lombard Street and Fenchurch Street, were in flames; the fire then was burning in the form of a bow.

When the first panic was over, and the fire spread so rapidly that no person could calculate on the safety of his house, great exertions were made to remove the property into the adjacent fields, which, for many miles round, were strewed with all sorts of moveables. Five, ten, and even fifty pounds were given for a cart, to remove some valuable property about to be consumed—the boats and barges on the river were all laden; and 'scarcely a back, either of man or woman, that had strength, but had a burden on it in the street.'

The night of Monday was more dreadful than the preceding one; the fire shone with such a fearful blaze, that the streets were as light as from the sun at noon-day. After spreading, in one line westward, along the banks of the Thames, as far as Queenhithe, and in a parallel direction along Cornhill to the Royal Exchange, and northward to Dowgate and Watling Street, it divided itself into four branches, which united in one great flame at the eastern end of Cheapside: on Tuesday the whole of that street was in flames, and the fire was seen 'leaping from house to house, and street to street, at great distance one from the other.' The impetuous flames now advanced with lawless power to the cathedral of St. Paul's; 'the stones of which,' says Evelyn, 'flew like granados, mealting lead running down the streetes in a streame, and the very pavements glowing with a fiery rednesse, so as no horse nor man was able to tread on them, and the demolition had stopped all the passages, so that no help could be applied.' The neighbouring streets shared the same fate, and the writer just quoted draws a vivid feature of

the appalling scene: 'Oh the miserable and calamitous spectacle!' he exclaims, 'such as haply the world had not seen the like since the foundation of it, nor be undone till the universal conflagration. All the sky was of a fiery aspect, like the top of a burning oven, the light scene above forty miles round about for many nights. God grant my eyes may never behold the like, now seeing above 10,000 houses all in one flame; the noise and cracking and thunder of the impetuous flames, the shrieking of women and children, the hurry of people, the fall of towers, houses, and churches, was like an hideous storm, and the air all about so hot and inflamed, that at last one was not able to approach it, so that they were forced to stand still and let the flames burn on, which they did for neere two miles in length and one in breadth. The clouds of smoke were dismall and reached, upon computation, neere fifty miles in length. Thus I left it this afternoon burning, a resemblance of Sodom, or the last day. London was, but is no more.'

On Tuesday night, the devouring element continued its destructive havoc, sweeping away Ludgate Hill, the Old Bailey, the whole of Fleet Street, and the Inner Temple, and threatening even the Court at Whitehall, which now began to be alarmed, and gave directions to blow up several houses with gunpowder—a plan which, if adopted at the commencement of the fire, when it was suggested by some seamen, might have saved half the city; but this 'some tenacious and avaricious men, aldermen, &c., would not permit, because their houses must have been of the first.'

On Wednesday morning, when the inhabitants of Westminster and the suburbs were preparing to flee from the flaming sword which seemed to pursue them, the wind was hushed, the fire was stayed, and a remnant of London was saved. The first effectual check that the fire encountered was the brick buildings of the Temple, which were only partially consumed, and although the fire broke out again here on the Thursday evening, the duke of York, who watched there the whole of that night, caused the houses in front of it to be blown up, by which means the flames were extinguished.

To aggravate the ruin and distress in which the citizens were involved, by the loss of their houses and their property, the most alarming reports were spread. It was rumored that persons had been taken with fire balls and matches, in the act of attempting to set fire on the city in other places. This so enraged the multitude, that they killed a poor woman who had something concealed in her apron, which they conceived to be fire balls, and wounded several other persons, particularly French and Dutch, against whom they felt very indignant. A more alarming rumor was circulated on the Wednesday night; when the inhabitants were lying in tents in the neighbouring fields, it was reported, that 'the French were coming armed against them to cut their throats, and spoil them of what they had saved out of the fire.' Despair roused the citizens, and, fired with indignation, they prepared to defend themselves; but morning dispelled their uneasiness, and brought

with it the joyous prospect that the fire was subdued, and that no new calamity threatened them.

Nothing could exceed the zeal and activity of the king and the duke of York during the whole of the dreadful scene: they traversed the city night and day, encouraging the laborers, where they thought there was the slightest chance of arresting the progress of the flames, and personally directing every measure for that purpose: to this energy, and to a corresponding vigilance on the part of the magistracy and the train bands, must be attributed the circumstance, that so few lives were lost, and so few outrages committed.

The extent of the ravages covered a space of 436 acres; as the boundaries are fixed in the official account of the fire, which appeared in the London Gazette of the 10th of September. It is here stated, that a stop was put to it at 'the Temple Church, near Holborn Bridge, Pye Corner, Smithfield; Aldersgate, Cripplegate, near the lower end of Coleman Street, at the end of Basinghall Street, by the postern at the upper end of Bishopsgate Street, and Leadenhall Street, at the standard in Cornhill, at the church in Fenchurch Street, near Clothworkers' Hall in Mincing Lane, at the middle of Mark Lane, and at the Tower Dock.'

In the British Museum there are forty-one folio volumes of the Decisions of the Commissioners on the claims of the persons who had suffered by the fire, but they do not furnish any account of the aggregate loss, nor could it, indeed, be very accurately ascertained. The inscription on the monument, founded on the reports of the surveyors, states that of the six and twenty wards it utterly destroyed fifteen, and left eight others shattered and half burnt; that it consumed 400 streets, 13,200 dwelling houses, eighty-nine churches, beside chapels, four of the city gates, the Guildhall, with several public buildings, hospitals, schools, libraries, and a vast number of stately edifices. In a tract, printed in the Harleian Miscellany, there is an estimate of the value of the property destroyed, in which the number of houses is calculated at 12,000; they are valued, one with another, at £25 per annum, which, at twelve years' purchase, make the whole amount to £3,600,000. The cathedral, the churches, and other public buildings, are valued at £1,800,000; the personal property and goods at a similar sum; £20,000 in wharfs; and £150,000 in boats and barges, cart loads of furniture, &c.; making in the whole £7,370,000: but it is supposed, that this calculation is much too low, and that the property destroyed could not be less than £10,000,000 sterling.

Great as the calamity was, and convinced as the citizens were that it had been the work of incendiaries, yet they bore it with patience and resignation, and thought only of repairing their loss and restoring the city, which they did so successfully, that Burnet says: 'to the amazement of all Europe, London was, in four years time, re-built with so much beauty and magnificence, that we, who saw it in both states, before and after the fire, cannot reflect on it, without wondering where the wealth could be found to bear so vast a loss as was made by the fire, and

so prodigious an expense as was laid out in rebuilding the city.' It is very remarkable that, during the whole time of the fire, and amidst all the alarm and confusion it occasioned, not more than six persons perished, and those principally by venturing incautiously over the ruins; nor do the bills of mortality appear to have been increased by the houseless condition to which so many thousands of persons were reduced, when compelled to live in huts erected in Smithfield, Finsbury, and Moorfields, and other places in the vicinity of the metropolis.

'Although so indiscriminate and so dreadful an act of vengeance, as that of destroying a whole city, can scarcely be supposed to be harboured by any human being, yet there is strong reason to believe,' say the brothers Percy, 'that the city was set on fire by incendiaries, and that in more places than one. The Roman Catholics have always stoutly denied it, and compare the accusation to that of Nero against the Christians, whom he charged with setting fire to Rome; and Pope, knowing that an invective or an assertion is better recollected and lives longer in verse than prose, has, in two lines on the monument, declared, that the accusation against the Roman Catholics is false. If, however, the circumstances were to be decided according to the rules of circumstantial evidence, we believe it would be fully established, that the fire was not accidental. Lord Clarendon, who certainly cannot be suspected of any illiberal prejudices, and would rather attribute the fire to chance than design, says, 'the breaking out of the fire in several places, at so great distance from each other, made it evident, that it was by conspiracy and combination;' that 'it could not be conceived how a house, that was distant a mile from any part of the fire, could suddenly be in a flame without some particular malice; and this case fell out every hour.' The noble author next alludes to Herbert, who was executed for the crime; and although his examination was somewhat contradictory, yet his confession was sufficiently explicit; for, when he was taken by the committee to identify the place, he pointed out the site of the house where the fire commenced as that which he and his accomplices had set on fire. Even lord Clarendon, who maintains Herbert's innocence, furnishes very strong proof of his guilt, in his account of his confession: he says, 'the house, and all which were near it, were so covered and buried in the ruins, that the owners themselves, without some infallible mark, could very hardly have said where their own houses had stood; but this man led them directly to the place, described how it stood, the shape of the little yard, the fashion of the door and windows, and where he first put the fire; and all this with such exactness, that 'they who dwelt long near it, could not so perfectly have described all particulars.'

Farryner, the baker, in whose house the fire originated, confidently asserts that it was set on fire; but whether Herbert was really guilty or not, or was, as his advocates contend, insane, there is evidence which is more than presumptive, that the city was wilfully burnt; it is not the deposition of prejudiced persons after the

fire happened, but evidence that the design existed many months before it was carried into effect. In the London Gazette, No. 48, for April 30th, 1666, there is an account of the conviction at the Old Bailey sessions, of John Rathbone, 'an old army colonel,' and several others, for conspiring the death of his majesty, and the overthrow of the government; and it states that 'the better to effect this hellish design, the city was to have been fired, and the portcullis to have been let down to keep out all assistance; the horse-guards to have been surprised in the inns where they were quartered, several ostlers having been gained for that purpose. The Tower was accordingly viewed, and its surprise ordered by boats over the mote, and from thence to scale the wall. One Alexander, who is not yet taken, had likewise distributed sums of money to these conspirators; and, for the carrying on of the design more effectually, they were told of a council of the great ones that sate frequently in London, from whom issued all orders; which council received their directions from another in Holland, who sate with the States; and that the 3rd of September was pitched on for the attempt, as being found, by Lillie's almanack and a scheme erected for that purpose, to be a lucky day, a planet then ruling, which prognosticated the downfall of monarchy.' The account concludes with stating, that 'the evidence against these persons was very full and clear, and they accordingly were found guilty of high treason.'

At first the following inscription was placed on the house built on the site of Farryner's; but the number of persons it attracted to the spot caused it afterwards to be removed. 'Here, by the permission of heaven, hell broke loose upon this Protestant city, from the malicious hearts of barbarous Papists, by the hand of their agent Herbert; who confessed, and on the ruins of this place declared the fact for which he was hanged, viz. that here began the dreadful fire which is described and perpetuated on and by the neighbouring pillar, erected anno 1681, in the mayoralty of Sir Patience Ward, Knight.'

There have, since the above period, been some serious conflagrations in London, particularly the fire in Thames Street on the 15th of January 1715, when upwards of 120 houses, and an immense quantity of merchandise, were destroyed. This calamity was aggravated by the death of more than fifty persons, who perished in the flames, and by other accidents.

On the 25th of March, 1748, a most destructive fire broke out at a peruke-maker's shop in 'Change Alley, Cornhill, which continued for twelve hours, and totally destroyed nearly 100 houses, twenty of which were in Cornhill. Mr. Eldridge, his wife, children, and servants, all perished in the flames, and several other persons were killed by various accidents. The loss occasioned by this fire was estimated at £200,000.

On the 7th of November, 1765, a fire broke out in the house of a peruke-maker, in Bishopsgate Street, which destroyed, or greatly injured, 100 houses. All the houses from Cornhill to the church of St. Mary Outwich, in Bishopsgate

Street, were burnt down: as was the White Lion Tavern, which had been purchased only on the preceding evening for £3000; several persons were killed by the fire, and by the falling of chimneys; and the next day a gentleman, thinking that some persons were buried among the ruins, got the firemen to work with their pick-axes, when, on removing the rubbish, they drew out two men, three women, and a child about six years old, all alive.

During the riots of 1780, the King's Bench, Fleet, and Bridewell prisons were set on fire, as well as several houses in various parts of the metropolis. In 1793, on the 2d of December, an extensive range of warehouses, near Hermitage Bridge, Wapping, was destroyed by fire, together with several adjoining houses. Three vessels lying in the dock were also burnt. The goods destroyed consisted principally of sugar, rum, and hemp. Of the sugar, 1400 casks were melted into one mass by the intense heat, and flowed through the streets in a brilliant stream of liquid fire.

But the greatest conflagration known in London since 1666 was the fire in Ratcliff, which broke out at Cock Hill, on the 23d of July 1794. It was caused by the boiling over of a pitch kettle at a boat-builder's, from whose warehouses it communicated to a barge laden with saltpetre and other stores, and thence extended to several other vessels. The warehouses of the East India Company were also consumed, and nothing could arrest the progress of the destructive element, until, having reached an open space of ground towards Stepney, the flames ceased for want of materials. It was calculated that, out of 1200 houses, of which the hamlet consisted, not more than 570 were left standing. A calamity so sudden and so fatal called for the immediate and the liberal aid of both the government and the public, and it was freely given: 150 tents were forwarded from the tower, and pitched in a vacant piece of ground near Stepney Church. Provisions were supplied, in the first instance, by the parish to the poor sufferers. A subscription was opened at Lloyd's Coffee-house for their relief, and several gentlemen, who attended near the ruins to solicit the assistance of the benevolent, were so successful, that on the Sunday immediately after the fire upwards of £800 was thus collected, of which £426 was in copper, including £38 14s. in farthings; exhibiting a singular instance how universal the feelings of sympathy and benevolence must have been. The whole sum subscribed in various ways for the relief of the sufferers was more than £16,000.

Several other fires, which have done considerable damage to various parts of the metropolis, have occurred, but those above noticed are the principal ones. The more substantial and less inflammable nature of materials used in building, the width of the streets, the regulation of the building act as to party-walls, and the more ready supply of water, are all guarantees that London will never again be visited with those calamities, which have laid it in ashes, in the course of a few hours. The fires in London have more frequently originated in accident than de-

sign: and so convinced was the legislature of this, that in the act of 1708 it was enacted, 'that every servant, by whose negligence or carelessness a fire should be occasioned, should forfeit £100, or, in default, be imprisoned and kept to hard labor during eighteen months.'

3. *Wat Tyler's insurrection* has already been recorded in our article ENGLAND. After finding himself at the head of 100,000 men, this incendiary aimed at the subversion of the government, and marched to London, breathing vengeance against the nobility and the members of the legal profession. The public gaols, which were opened, added to the rebel army, now so numerous, some men of a determined character, and with talents well calculated for keeping alive the flame of rebellion, which had been so successfully kindled. Among those gaol recruits was the famous John Ball, the priest, who now became chaplain-general to the army. Wat Tyler had for associates several other daring men, who, making a merit of their humble occupations, assumed the fictitious names of Jack Straw, Hob Carter, and Tom Miller.

In their route to London they committed many excesses, putting to death several peers and gentlemen, and every lawyer that had the misfortune to fall into their hands. In their hostility to the duke of Lancaster, they bound themselves by an oath, never to acknowledge for king any man whose name was John. When the rebels arrived at Blackheath, the princess of Wales, the king's mother, who was returning from a pilgrimage to Canterbury, passed through the midst of their encampment. The rebels permitted her to proceed on her journey, though some of the most insolent of them obliged her to kiss them, and maltreated her retinue.

The rebels now sent a deputation to the king, who had taken refuge in the Tower, and desired to have an interview with him. For this purpose Richard sailed down the river in his barge; but, on approaching the shore, and witnessing many instances of tumult and confusion, he did not think proper to land, but returned to the Tower. The king then sent to know the object of their assembling, and what it was they asked. Wat Tyler was reviewing his army when the king's messenger arrived, and, confident in the numbers of the men he saw marshalled before him, he sent back an insolent message, stating, that their business was of such importance as only to be communicated to the king, whom they desired to meet them. This request having been refused, agreeably to the determination of the king's council, the rebels marched towards London, and were soon masters of Southwark, which they plundered. London bridge might have offered some obstruction to their progress; but the mob, on the city side, opened the gates in spite of the magistrates, and Wat Tyler and his army entered the city, where they committed the most wanton excesses. The duke of Lancaster's palace in the Savoy, the archbishop of Canterbury's palace, the Temple, the hospital of St. John's Clerkenwell, and the houses of the judges and principal citizens (but more particularly those of the Flemings) were razed to the ground. Against the Flemings their rage was unbounded:

they dragged them from the churches where they had taken sanctuary, and massacred them in the open streets. Plunder, the usual attendant of public tumult, was certainly repressed, as much as possible, by the leaders of the insurrection, who even threw into the fire, amongst a heap of burning wealth, one of their followers, who endeavoured to secure a piece of plate.

The rebels now approached the Tower, where the king, with his mother, the archbishop of Canterbury, the lord treasurer, and several of the nobility had taken refuge, when Richard sent word, that he would give them a meeting on Mile-End Green, and thither a large body of them, chiefly of the Essex party, accordingly repaired. As he was about to leave the Tower, however, a chosen band of Wat Tyler's followers rushed into the fortress, cut off the heads of the archbishop, the lord treasurer, Sir Robert Hales, and the chancellor, and pillaged the royal apartments. Wat Tyler remained near the Tower at the head of 30,000 men. Consternation now seized on the government, and, after some discussion, it was deemed advisable to offer the rebels a charter; not, however, confirming the privileges of the people, or redressing their grievances, but abolishing villainage, and offering a general pardon for all crimes committed during the insurrection. This charter, which was dated the 15th of June, was in the following terms:—
‘Richard, &c. Know, ye, that of our special grace, we have manumitted or set free all and singular our liege subjects, and others of the county of Essex; and them and every of them from all bondage do release and acquit, by these presents. And also we pardon to our said liege men and subjects, all manner of felonies, treasons, transgressions, and extortions by them, or any of them, in any manner whatsoever done or committed.’

Armed with this charter, the young king proceeded to Mile-End, where his offers were accepted by the Essex men, who immediately dispersed to their homes. The success which had here crowned the efforts of Richard, induced him to attempt a negotiation with the principal rebel leader. For this purpose he repaired to Smithfield, with a few attendants, and sent Sir John Newton to desire Wat Tyler to meet him. Wat Tyler would only, however, attend at the head of his troops. When entering Smithfield, he was met by the same knight, with another message from the king, but the bearer, delivering it without dismounting from his horse, so offended the dignity of Wat Tyler, that he raised his sword to strike him down. The king, however, interposed, and cried out to Sir John to dismount. In the conference that ensued, Tyler demanded much more than had been yielded to his fellow insurgents. Besides a general enfranchisement of bond-men, he required that all warrens, parks, and chases should be made free and common to all, so that the poor, as well as the rich, should have liberty to fish, fowl, and hunt in all places throughout the kingdom. It is, however, worthy of remark, that none of the rebels asked for the slightest modification of the poll tax, the grievance in which the insurrection had originated.

The insolence of Wat Tyler, who is said, du-

ring the conference, to have frequently raised his sword, did not provoke the resentment of the king; but it so roused the indignation of the lord mayor, William Walworth, that, with a sword or dagger, he struck the rebel dead at his feet, and thus terminated the rebellion. See ENGLAND. Richard immediately knighted on the field the lord mayor, Walworth, and several of the aldermen, for their important services at this difficult crisis.

Thus terminated one of the most extraordinary and most formidable insurrections that London ever witnessed. Like most other popular commotions, it presented instances of private revenge, more striking than those of public feeling, and that too, in two of the most prominent characters who figured in it, Wat Tyler and Sir William Walworth. The former had been in the service of Richard Lions, an eminent wine merchant, and sheriff of London, who had inflicted personal chastisement upon him. When the rebel chief reached London, he caused his old master to be beheaded, and his head carried before him on the point of a spear, though it is, perhaps, too much to charge this act on Wat Tyler's resentment, since to be rich was a sufficient crime to insure the punishment. As for Sir William Walworth, whose name is perpetuated in a populous suburb, his loyalty is, perhaps, as questionable as Wat Tyler's patriotism. He was a principal sufferer by the insurrection, which had levelled to the ground a number of tenements which this citizen possessed on the bank side, and which were let out for the very worst of purposes. It is not too much, therefore, to suspect, that private feeling may have prompted his activity to put down the rebellion, and punish its leader.

4. *Jack Cade's Rebellion.*—Shakspeare, who ‘exhausted worlds and then imagined new,’ has rendered the insurrection of Jack Cade, in 1450, better known in the second part of his play of Henry VI. than it would have been had it been recorded only in history. With that license, which to poets is never denied, he has turned into ridicule an event, which occasioned no ordinary degree of alarm at the time, and has, by the extravagancies which he makes its leaders commit, thrown a discredit on popular insurrections, from which it is difficult to divest them. Not content with demolishing public buildings, and the houses of the wealthy, our bard makes Jack anxious to burn all the records of the realm, that his mouth may be ‘the parliament of England. Denying that

—‘ignorance is the curse of God,
Knowledge the wing wherewith we fly to heaven,’

Cade is represented as having a particular enmity to learning. He makes it one of his most serious charges against lord Say and Sele, that he had ‘most traiterously corrupted the youth of the realm in erecting a grammar school,’ and adds this more sweeping accusation: ‘whereas before, our forefathers had no other books but the score and the tally; thou hast caused printing to be used, and, contrary to the king, his crown, and dignity, thou hast built a paper mill. It will be proved to thy face, that thou hast men

about thee, that usually talk of a noun and a verb, and such abominable words as no Christian ear can endure.'

Whatever designs Jack Cade might have had after striking his sword on London stone, and exclaiming 'now is Mortimer lord of this city,' he was, in the first instance, only the tool of others. The struggles of the rival houses of York and Lancaster, though not terminated, had a momentary cessation, when Richard, duke of York (whose son succeeded to the throne, under the title of Edward IV.) aspired to the crown. He was at this time in Ireland; and although the disasters of the government, in the loss of Normandy, had increased the number of his adherents, yet he did not choose himself to hazard an attempt to seize the crown. He enlisted Jack Cade, a daring Irishman, in his service, who, well supplied with money, and assuming the name of John Mortimer, of the house of March, executed in the early part of the reign, proceeded to Kent, where the duke had many friends. Here, in May, 1450, he hoisted the standard of insurrection, which was soon so numerously attended, that Jack Cade was strong enough to insult the city, and encamp as near it as Blackheath.

The king, determining to put down the insurrection by force of arms, assembled a body of 15,000 men, with which he marched against them. On his approach Jack retired, and lay in ambush in a wood near Sevenoaks. The king, imagining the rebels were dispersed, sent a detachment after them, under the command of Sir Humphrey Stafford. This detachment (see ENGLAND) falling into the ambush was cut to pieces, and the commander, as well as his brother, killed.

Cade now marched towards London, while the king and his court hastily fled to Kenilworth, leaving a garrison in the Tower, under the command of lord Scyles. The city of London opened her gates to the rebels, and Cade entered in triumph at the head of his troops; but he prohibited, under the severest penalties, any injury being done to the inhabitants. He did not, however, take up his residence in the city, but in the borough of Southwark. On the second day he seized on the lord treasurer, lord Say, and had him beheaded. The Londoners seemed on very good terms with his followers, until some of the soldiers committed a riot in the city; the next morning, when Cade was about to enter the city as usual, he found the gate on London Bridge shut against him: a severe battle now ensued, which lasted all day. In the night a proclamation was issued by the government, offering a free pardon to all who laid down their arms. This being actively circulated through Southwark, next morning Jack Cade was deserted by his followers, and fled into Sussex, where he was killed by Alexander Iden or Eiden as we have already stated. Many of his followers were executed.

5. *The Bastard Falconbridge's attack*—The bastard of Falconbridge, eldest son, as Shakspeare says,

To Robert Falconbridge,
A soldier by the honor-giving hand
Of Cour-de-Lion, knighted in the field,

having collected, in Essex and Kent, a considerable force of ships and men, sailed up the Thames to London, resolving, as at Angiers, to beat

'The flinty ribs of this contemptuous city,

Even till unfenced desolation
Should leave them naked as the air.'

Falconbridge, however, found the 'saucy walls of London too much even for his 'heavy hand. The citizens flew to arms in great numbers, and defended themselves gallantly. The bastard made his first attack by the river side of the city, which, in consequence of the ruin into which the walls in that direction had been suffered to fall, presented the least chance of resistance; but he found so many stout hearts arrayed in defence of every breach, that all his attempts to effect an entrance on this side were unavailing. After firing some houses on London Bridge, he returned down the river, and, at some distance below the Tower, landed his forces, amounting to about 5000 men, with the view of attacking the city, by land from the eastward. On Sunday, the 11th of May, the assault was made at Aldgate; the bulwarks were won; and the assailants were pushing boldly forward, when the portcullis was let down, and such as had entered the city were cut to pieces. Robert Basset, the alderman of Aldgate Ward, who commanded at this point, animated with a spirit as valiant as that of the bastard himself, was not, however, content with repulsing the enemy; for we are told, that he 'commanded, in the name of God, the portcullis to be drawn up; which being done they issued out, and with fierce fight drove their enemies back as far as St. Botolph's Church.' The lieutenant of the Tower, observing the success of this spirited sally, issued forth with the earl of Rivers at the head of a fresh company, and joining the brave alderman Basset, assisted him to put the enemy completely to the route. The pursuit was continued as far as Stratford; many of the enemy were slain, and many taken prisoners. The bastard only escaped, with the wreck of his forces, on board of his ships.

6. *The plague years.*—In former ages scarcely ten years elapsed in London without the visitation of this tremendous scourge. The narrow streets in which the current of air was either obstructed by architectural projections, or by the signs across them, together with the want of cleanliness, owing to the inefficient supply of water, and the want of regulations to prevent the accumulation of filth in the streets, did much to increase if not even to generate that disease, which under this name occupies so prominent a place in the severe calamities of the British metropolis.

In the middle ages the church yards are said to have groaned with the bones of the dead, piled up, and exposed to the air which they corrupted—the streets were filled with garbage and filth which no exercise of authority could compel the inhabitants to remove—the sewers, which generally ran above ground, were in a neglected state, while the sluttishness within doors corresponded with the filthiness of the streets without. As early as the fourteenth century we find the plague attributed to want of cleanliness; for when, in

the year 1361, it was dreaded that the plague, which made its appearance in France, would cross the channel, the king sent a letter to the mayor and sheriffs of London, commanding that cattle should not be killed nearer than Stratford-le-Bow or Kensington. Even as late as the memorable years 1625 and 1665, the plague was attributed to this want of cleanliness; and the tracts of the time are full of complaints on the subject. 'Let not carcases of horses, dogs, cats, and other animals,' says the author of a pamphlet, entitled *Certain Rules, Directions, and Advertisements on the Plague*, printed in London in 1625, 'lye rotting and poisoning the air, as they have done in More and Finsbury Fields, and elsewhere, round about the citie.' Another author of the same period distinctly attributes the plague to all sorts of unsavory stench, proceeding either from carrion, ditches, and rotten dunghills, vaults, sinks, nasty kennels, and streets strewn with all manner of filth, seldom cleansed; these fetid smells are the maintaining cause of the contagion.

Although there is strong reason to believe, that for some centuries, the city was not wholly free from the plague; yet there have been particular years when it has broken out with singular fury, and which on this account have been denominated plague years. Independently of those which have been general to the country, we find London has suffered more immediately on several occasions. The year 1348 is distinguished by a dreadful pestilence, which is said to have originated in India, and thence spread over all the globe. Historians relate, that it fell with so much force on London, as scarcely to leave a tenth person of all sorts alive. The ordinary cemeteries were insufficient, and burial grounds were opened in several places beyond the walls of the city, where the dead were heaped in indiscriminate confusion: 50,000 persons perished in London alone. The years 1361 and 1369 were also plague years, but less fatal to London than that of 1407; when 30,000 were swept from the metropolis. The plague of 1479, though of short duration, only from September to November, was very destructive, but nothing equal to that of 1499—1500, when another 30,000 of the citizens of London were hurried to a premature death. The king and court, taking the alarm, removed from place to place, and lastly to Calais, then belonging to England, in order to avoid the infection. In a former year, 1485, if we are to believe Hall, a sweating sickness killed two mayors and six aldermen in one week. The pestilences of 1513, 1525, and 1548, were also severe. During that in 1525, Michaelmas term was adjourned, and the king removed to Eltham, where he kept his Christmas with so unusually small a court, that it was called the still Christmas.

In the plague of 1563-1564, 20,000 persons died in London, and the lawyers suspended one term, and removed the sittings of another to Hereford Castle; while, in that of 1574, the city banquet at Guildhall on the installation of the new lord mayor, was dispensed with by order of the queen. The plague of 1582 carried off nearly 7000 persons, and that of 1592 more than 11,000.

Almost every succeeding plague exceeded its predecessor in severity; that which followed in 1603, on the succession of James VI. of Scotland to the throne, was particularly fatal. The citizens had welcomed the king to London in great triumph, and conducted him to the Charter House, where he had a most royal entertainment for four days, given to him by lord Thomas Howard. Great preparations were also made in the city for the coronation, but these were interrupted by the plague, which was by this time considerably increased. The coronation indeed took place, but it was stripped of the pomp and circumstance of a city pageant. Their majesties rode not through the city in royal manner as had been accustomed, nor were the citizens permitted to behold the ceremonial at Westminster, being forbidden by proclamation to repair thither, with the exception of the lord mayor, and such of the citizens as, by virtue of the ancient claim, assisted the chief butler at the coronation.

The courts of law were removed; Michaelmas term was held at Winchester, and the courts of exchequer at Richmond. Bartholomew fair and all fairs within fifty miles of the metropolis were suspended; and James issued several proclamations for preventing any further increase of build-ings.

The great plagues have not been wanting in historians. That of 1603 has found an eccentric, but by no means inelegant chronicler, in a black letter tract, entitled *The Wonderful Yere 1603*, wherein is showed the picture of London, lying sicke of the plague. At the end of all (like a merry epilogue to a dull play), certaine tales are cut out in sundry fashions, of purpose to shorten the lives of the long winter nights, that lye watching in the darke for us. The author gives a most vivid description of this horrible pestilence. He compared the citie to a vast silent charnel house, with lamps dimly and slowly burning, where the pavement, instead of green rushes, is strewn with blasted rosemary, withered hyacinths, fatal cypress, and yew thickly mingled with heaps of dead mens' bodies; the bare ribs of a father that begot him lying there; here the chaplesse hollow sculle of a mother that bore him, round about him 1000 corse; and even such he says was the city:

'For he that durst, in the dead hour of gloomy midnight, have been so valiant as to have walkt through the still and melaucholy streets, what thinke you should have been his musicke. Surely the loud groanes of raving sicke men: the struggling panges of soules departing. In every house grieve striking up an alarum; servants crying out for masters, wives for husbands, parents for children, children for their mothers; here he should have met some frantically running to knock up sextons; there others fearfully sweating with coffins, to steale forth dead bodies, least the fatal hand writing of death should seale up their doores.

'How often,' continues this writer, 'hath the amazed husband waking, found the comfort of his bedde lying breathlesse by his side; his children at the same instant gasping for life; and his servants mortally wounded at the heart by sickness, the distracted creature heats at death's doores, ex-

claimes at windows, his cries are sharp enough to pierce heaven, but on earth no eare is opened to receive them ! And in this manner do the tedious minutes of the night stretch out the sorrow of 10,000.

‘ It is now day, let us looke forth and try what consolation rises with the sun ; not any, for before the jewel of the morning be fully set in silver, 100 hungry graves stand gaping, and every one of them (as at a breakfast) hath swallowed down ten or eleven lifelesse carcases : before dinner in the same gulfes are twice so many more devoured : and before the sun takes his rest, those numbers are doubled. Threescore, that not many houres before had every one several lodgings here very delicately furnisht, are now thrust altogether into one close room—a little noisome roome not full ten feet square.’

The tales which the author introduces, to shorten the lives of long winter nights, are many of them as pathetic as his general description, though some of them have touches of humor, which show that he was no ordinary master of the passions. One of the most affecting is that of a young couple who went to church to get married, when the bride was so ill, that, ‘ had not the holy officer made haste, the ground on which she stood to be married might easily have been broken up for buryall.’ She was led not like a bride, but rather like a corse to her bed, and died in a few days.

The number of persons who fell victims to the plague, is during this year, estimated by some historians at 30,561 ; and by others at 30,578 ; but, as the total number of deaths in the city from March to December was 37,294, it is probable that a larger portion of them fell by the plague than is here assigned to it.

The plague of 1625 was still more destructive, sweeping off from a city already half desolated 35,000 persons in one year. The coronation of Charles I., like that of his father, king James, was shorn of its accustomed honors, particularly the procession through the city from the tower. In Whitelocke’s Memorials we find a curious anecdote of the terror created by this dreadful scourge. He says, ‘ When the plague was somewhat assuaged, and there died in London but 2500 in a week, it fell to judge Whitelocke’s turn to go to Westminster Hall, to adjourn Michaelmas term to Reading ; and accordingly he went from his house in Buckinghamshire to Horton, near Colnbrooke, and the next morning early to Hyde Park Corner, where he and his retinue dined on the ground, with such meat and drink as they brought in the coach with them ; and afterwards he drove fast through the streets, which were empty of people, and overgrown with grass, to Westminster Hall, where the officers were ready, and the judge and his company went strait to the king’s bench, adjourned the court, returned to his coach, and drove away presently out of town.’

In the MSS. in the British Musuem there are several original letters written during the time of this plague, by Mr. Mead to Sir Martin Stuteville, one of his friends, which give some curious particulars relating to this malady which have escaped the historians of the time. Mr. Mead lived at Christ Church, Cambridge, at the time ;

but he appears to have had letters every week from Dr. Meddus, the rector of St. Gabriel’s, Fenchurch. In a letter, dated July 2d, 1625, Mr. Mead states that there were fifty parishes infected within the walls ; and, as an instance of the very sudden manner in which the hand of death was laid on individuals, he mentions that ‘ My lord Russel (afterwards fourth earl of Bedford), being to go to parliament, had his shoemaker to pull on his boots, who fell down dead of the plague in his presence, whereupon he abstains from that honorable assembly, and hath sent the lords word of this accident.’

In a letter, written the week after, Mr. Mead enumerates the deaths by the plague as in one week 593, and states that the intercourse between Cambridge and London was stopped. Hobson the famous carrier, of ‘ Hobson’s choice’ memory, had gone his last journey in the preceding week. The infection appears to have been at its height in the latter end of July : the deaths during that week were 3583, of whom 2471 were allowed to have died of the plague ; and Mr. Mead attributes the deaths of the greatest part of the remainder to what he calls the invisible plague.

Dr. Meddus, in one of his letters to Mr. Mead, relates the following very credible anecdote : ‘ A woman near the Old Swan, removing into Surrey for fear of the plague, when she was come on the hill, near Streatham, in the way to Croydon, turned back, looked on the city,’ said, ‘ Farewell London and farewell plague, but soon after was taken sick, had the tokens on her breast, and these words to be distinctly read, ‘ It is in vain to fly from God, for he is every where.’ Mr. Mead, in communicating this anecdote to Sir M. Stuteville, adds, ‘ You may judge of this or suspend it as you please.’

This gentleman was not however exempt from the superstitions of the time, for in another letter, dated September 4th, he says ‘ We have some here, make an observation that the first abatement of the plague was the week next following that, wherein came out the proclamation against papists, and it is true by the date thereof : but let me add my observation too, that, as the walls of Jericho fell down, when the priests with the ark of God had compassed it, blowing trumpets seven days or times ; so is the fall of the sickness, after the seventh general fast, accounting that general representative of the whole parliament for one.’

The plague in the year 1636 was less destructive ; though this does not appear to have been in the least owing to an improved mode of treatment, or that necessary means of preventing it, cleanliness in the houses and streets, since at a much later period, we find complaints on this account as strong and as frequent as ever. During this year, from April to December, the number of persons who died was 23,357, of whom only 10,400 are supposed to have perished by the plague.

At length the metropolis was consigned for a whole year to a pestilence more obstinate in its nature, and more destructive in its effects, than any that had preceded it. Although the plague of 1665, the Great Plague as it is called, to distinguish it from all others, is generally supposed to have

been brought from the Levant in some goods imported through Holland by a tradesman in Long Acre; (yet, independently of the doubt, which exists as to this disease being at all importable), there is strong reason to believe that it is to be attributed to the same causes, that produced those which preceded it, the narrow streets, confined air, and want of cleanliness. This seems the more probable, as for a long period London had not been wholly free from the plague. Maitland says, for five and twenty years previous to 1665, it had not been clear of the malady, and that even from the year 1603 until 1670, the bills of mortality exhibit but three years, in which London, more or less, was not afflicted with the plague.

Even in 1665, when it broke out with unresisting fury, the populace considered it only as one of the judgments of the Almighty, to which submission was all they could offer, and conceived that to oppose it would be a mockery, or an insult to the deity. The very fears and superstitions of the people were no inconsiderable auxiliaries to the plague; and they considered themselves as doomed to destruction, by the appearance of the heavens, and by a thousand indications, which, though as nothing in the eyes of philosophy, bring to the timid and superstitious confirmations strong as proofs of Holy Writ. A comet, which had appeared some months before the plague, was, when it broke out, considered as having foretold a judgment slow but severe, terrible and frightful.

These apprehensions were much increased by the pretended prophecies and astrological calculations of a set of impostors, who pretended to be better acquainted with the future than their neighbours. They fabricated stories of malignant conjunctions of the planets, and levied from the credulous no inconsiderable sums, until the hand of death, which respected not their knowledge, levelled them with the dupes of their artifice. So eager were the people to consult fortune-tellers and conjurors, that 'if but a grave fellow,' says the author of the History of the Great Plague, attributed to Defoe, 'in a velvet jacket, a band, and a black coat, which was the habit those quack conjurors generally went in, was but seen in the streets, the people would follow them in crowds, and ask them questions as they went along. The almanacks too proved a source of terror, and the coming plague was thought to have been fixed in Lilly's Almanack, Gadbury's Astrological Predictions, and Poor Robin's Almanack.

Fanatics or visionaries are said also to have run through the streets, agitated and agitating by their oral denunciations and predictions. One man ran about in a state of wild disorder, crying day and night like the man mentioned by Josephus, whose Woe to Jerusalem preceded and foretold its fall; he walked quickly, and, with a voice and countenance beaming with horror, continually ejaculated 'O the great and dreadful God.' Another man, pretending a more than human authority for preaching to the city, went about like Jonah in the city of Nineveh, crying out 'Yet a few days and London shall be destroyed.' However imaginary these horrors were, a fearful reality was soon experienced.

The plague first began in Long Acre, towards the close of the year 1664, when, two or three persons suddenly dying in one family, the timid neighbours took the alarm and removed into the city, whither they are supposed to have unfortunately carried the infection. Here it gathered strength from the denseness of the population, and soon its ravages became extensive. The lower classes were seized with a panic; and entertaining an absurd, but very general notion, that the plague visited London every twenty years, they took no means to counteract it.

A frost, which set in in December, and continued three months, if it did not exterminate the distemper, suspended its destructive effects; but, no sooner had a thaw succeeded, than it burst forth with increased force. From the month of February the plague began to advance; and, when it was discovered that it had extended to several parishes, the magistrates issued an order, dated 1st July, 1665, to shut up all the infected houses, which were marked with a red cross, bearing this inscription, 'Lord have mercy upon us.' Guards were constantly in attendance, to supply the sick with the necessary food, and to prevent their quitting their houses until forty days after recovery. This precaution is thought to have done much injury. Dr. Hodges, in his Loimologia, says, he verily believes that 'many who were lost might have been alive, had not the tragical mark upon their door driven proper assistance from them.' The same author adds, that what greatly contributed to the loss of the people thus shut up was, the wicked practice of nurses. 'These wretches,' says he, 'out of greediness to plunder the dead, would strangle their patients, and charge it to the distemper in their throats! Others would directly convey the pestilential taint from sores of the infected to those who were well.' This is a serious charge, but it is not without a parallel in our own times; for, during the last Russian campaign, some Jews who were employed in clearing the hospitals of Wilna of the dead, at a certain sum per head, were actually detected in throwing the sick and wounded out of the window, in order to augment the number.

The plan of shutting up the houses had been first adopted in the plague of 1603, when an act of parliament was passed to authorise it, entitled An Act for the charitable Relief and ordering of Persons infected with the Plague. If, on the one hand, it might be contended, that, by suffering persons to leave houses infected by the plague, they might extend its ravages, it must on the other be allowed as more than probable, that in many cases whole families fell victims to it, who might have lived, had they been allowed to quit the house on the first appearance of infection in any one of the family.

If the destroyer, when only stalking forth among men free to fly from his approach, and to shrink from contact with him, committed such havoc, it may be imagined how fell his ravages must have been among persons thus pent up together. Even those who retained full possession of health might calculate the hours they had still to live; those who to-day turned out the bodies of their lifeless companions, might lay

their certain account with following them on the morrow; no hope of escape being left to any, all must have prepared to die; and this consolation at least they must have had, that neither fear nor apprehension could any longer interfere with the tender offices of friendship and affection. The surviving son needed not to shrink from closing the eyes of his dying parent, nor the widowed wife from pillowing her head on the cold breast of her departed spouse.

Rigorous as the prohibition to quit an infected house was, yet some were found to brave it. In the City Remembrancer, for 1665, it is related that 'a citizen broke out of his house in Aldersgate Street, and attempted, but was refused, going into the Angel or the White Horse at Islington. At the Pyed Horse he pretended going into Lincolnshire, that he was entirely free from infection, and asked lodgings for the night. They had but a garret bed empty, and that but one night, expecting drovers with cattle next day. A servant showed him the room, which he gladly accepted. He was well dressed; and, with a sigh, said he had seldom lain in such a lodging, but would make a shift, as it was but for one night, and in a dreadful time. He sat down on the bed, desiring a pint of warm ale, which was forgot. Next morning, one asked what was become of the gentleman? The maid, starting, said she had never thought more of him; he bespoke warm ale, but I forgot it. A person going up, found him dead across the bed; his clothes were pulled off, his jaw fallen, his eyes open, in a most frightful posture; the rug of the bed clasped hard in one hand. The alarm was great, having been free from the distemper, which spread immediately to the houses round about. Fourteen died of the plague that week in Islington.'

In the months of May, June, and July, the plague had continued with more or less severity; but in August and September it quickened into dreadful activity, sweeping away 3000, 4000, 5000, and sometimes 8000 persons in a week. Then it was that the whole British nation wept for the miseries of the metropolis. In some houses, carcases lay waiting for burial, and in others, persons in their last agonies; in one room were heard dying groans, and in another the ravings of delirium, mingled with the wailings of relations and friends, and the apprehensive shrieks of children. Infants passed at once from the womb to the grave. 'Who would not,' says Dr. Hodges, 'burst with grief, to see the stock for a future generation hang upon the breast of a dead mother, or the marriage-bed changed the first night into a sepulchre, and the unhappy pair meet with death in their first embraces? Some of the infected ran about staggering like drunken men, and fell and expired in the streets; while others lie half dead and comatose, but never to be waked but by the last trumpet.'

The divine often received the stroke of death in the exercise of his sacred office; the physician, finding no assistance in his own antidotes, died while administering them to others. The soldiery, retiring from an enemy with whom human power could not cope, encamped in the suburbs of the

city; but were overtaken, and tell unresisting victims of the great destroyer. Business was suspended; and if in the market a solitary individual was seen purchasing the means of life, that life was often terminated ere he reached his home. The bells seemed hoarse with tolling; and the sextons were not sufficient to bury the dead, with which the church-yards were so glutted, that they were thrown into pits, in heaps of thirty or forty together.

In the month of September the disease was at its height, and more than 12,000 perished in one week. Some persons recommended fires in the streets, and they were kindled for three days, though many of the physicians were against it; but, 'before the three days were quite expired, the heavens both mourned over so many funerals, and so wept for the fatal mistake, as to extinguish even the fires with their showers.' A fatal night succeeded, in which more than 4000 persons expired.

Those moving sepulchres, the 'dead carts,' continually traversed the streets; while the appalling cry, 'Bring out your dead,' thrilled through every soul not yet dead to feeling. Then it was that parents, husbands, wives, and children, saw all that was dear to them thrown with a pitchfork into a cart, like the offal of the slaughter-house, to be conveyed without the walls, and flung in one promiscuous heap, without the rites of sepulture, without a coffin, and without a shroud. Single graves were no longer dug in church-yards, but huge pits, sufficient almost to entomb a whole army. In Aldgate church-yard, after several pits capable of holding sixty or 100 bodies, had been dug and filled, the churchwardens caused one to be formed so large, that they were blamed, as making preparations to bury the whole parish. It was about forty feet in length, and fifteen or sixteen feet broad, and in some parts about twenty feet deep. Into this gulf they began to throw the dead on the 4th of September, and by the 20th of that month they had cast into it 1114 dead bodies, when they were obliged to fill it up, as it was within six feet of the surface. In other church-yards similar pits were dug, till they were choked with the dead, and additional burial grounds were formed in several parts of the town, some of which have ever since been used for the same purpose, while others have no trace of the dread calamity which first marked them out as sepulchres.

The burial ground in Bunhill-fields, in which many a nonconformist rests in peace, was first appropriated to that purpose during the plague. A piece of ground near the street called Old Bethlem, in Moorfields; and the plot at the top of Holywell Street, Shoreditch; and a third in Goswell Street, were also used as temporary burying grounds on this melancholy occasion. Stepney, though at this time it had three distinct burying grounds, overcharged them all with its dead; and there were no fewer than five other pieces of ground devoted to this purpose. On two of these the parish churches of St. Paul, Shadwell, and St. John, Wapping, have since been built. A green field at the upper end of Hand Alley, Bishopsgate Street, was enclosed

for 'he parish of St. Botolph alone, though the inhabitants of some courts beyond its precincts were allowed to bring their dead to it. Two or three years after the plague, a scene took place here which seemed to bring back all the horrors of that dreadful period. The ground was purchased by Sir Robert Clayton, who immediately let it out on building leases. In digging the ground for the foundations, numberless bodies were dug up; 'some of them,' says the author of *Reflections on the Bills of Mortality*, 'remaining so plain to be seen, that the women's skulls were distinguished by the long hair, and of others the flesh was not quite perished.' On complaint being made, the bodies were removed to another place in the same ground, where 'the ground,' says the same author, 'is palisadoed off in a little square, where lie the bones and remains of 2000 bodies, carried by the dead carts to the grave in one year.' Horrible as these pits were, constables were obliged to be placed near them during the plague; for it was not unusual for persons infected, either seized by a fit of delirium, or, what is more probable, anxious to mingle with the bodies of all that was dear to them, to steal from their houses unobserved, or obtain an egress by bribing the watchmen, and wrapped in blankets and rugs, to throw themselves among the dead.

In this wreck of a city, which was half entombed, delirium hurried many even to a premature death. 'People,' says Defoe, 'in the torment of their swellings, which was indeed intolerable, running out of their own government, raving and distracted, and oftentimes laying violent hands upon themselves, throwing themselves out at their windows, shooting themselves, &c. Mothers murdering their own children in their lunacy, some dying of mere grief and passion, some of mere fright and surprise, without any infection at all; others frightened into despair and lunacy; others into melancholy madness.' Many were the cases in which the mother and her unborn offspring perished at once; in others where they died for want of proper assistance in the hour of nature's sorrow. Others frequently sucked the fatal poison from the lips of their dying infants.

The plague reached its height in August, and during that month and September 50,000 perished.

It was now that the dead carts were insufficient for the office, and the houses and streets were rendered tenfold more pestilential by their unburied dead. All who had survived now made the attempt to escape, and eighteen or twenty watchmen were killed in opposing the people when fleeing from the infected houses.

The change which now took place in the feelings of the people is thus vividly described by Defoe. 'As I have mentioned how the people were brought into a condition to despair of life, and abandon themselves, so this very thing had a strange effect among us for three or four weeks; that is, it made men bold and venturous; they were no more shy of one another, or restrained within doors, but went any where and every where, and began to converse. One would say to another, 'I do not ask you how you are, or say how I am. It is certain we shall

all go; so 'tis no matter who is sick or who is sound;' so they run deliberately into any place or company.'

The moral lesson conveyed in the following passage is worthy of being kept in everlasting remembrance. 'As it brought the people into public company, so it was surprising how it brought them to crowd into the churches; they enquired no more whom they sat near to, or far from, what offensive smells they met with, or what condition the people seemed to be in; but, looking upon themselves all as so many dead corpses, they came to the churches without the least caution, and crowded together, as if their lives were of no consequence, compared to the work which they came about. Indeed, the zeal which they showed in coming, and the earnestness and affection they showed in their attention to what they heard, made it manifest, what a value people would all put upon the worship of God, if they thought every day they attended at the church that it would be their last. Nor was it without other strange effects; for it took away all manner of prejudice at, or scruple about, the person whom they found in the pulpit, when they came to the churches. It cannot be doubted, but that many of the ministers of the parish churches were cut off among others in so common and so dreadful a calamity; and others had not courage enough to stand it, but removed into the country as they found means to escape. As then some parish churches were quite vacant and forsaken, the people made no scruple of desiring such dissenters as had been a few years before deprived of their livings, by virtue of the act of parliament, called the act of uniformity, to preach in the churches; nor did the church ministers in that case make any difficulty of accepting their assistance; so that many of those whom they called silenced ministers had their mouths opened on this occasion, and preached publicly to the people.' It will be remembered how well the zeal and fidelity of these ministers was requited when the danger was over, by the act of uniformity.

The dead now were no longer numbered; for the parish clerks and sextons perished in the execution of their office. In the parish of Stepney alone, 116 sextons, grave-diggers, and carters employed in removing the dead bodies, died in one year; 10,000 houses were at once deserted, and it is said that, during the plague, not fewer than 20,000 persons quitted the metropolis.

Empty the streets in uncouth verdure clad
Into the worst of desarts sudden turned
The cheerful haunts of man.

In the last week of September, the plague began somewhat to abate, and the bills of mortality fell from upwards of 8000 to little more than 6000 weekly. Every succeeding week the number of victims diminished; so that by the month of February, in the following year, the pestilence had wholly ceased. The number that perished during this plague, according to the returns, was 68,590; but Defoe asserts, that the number was at least 100,000. The lives of a great many persons were preserved by means

of the shipping on the Thames, into which the infection did not reach except in a very few instances.

Even the survivors of this dreadful calamity would have perished of famine, but for the bounty of the affluent. The money subscribed is said to have amounted to £100,000 a week, to which Charles II. humanely gave £1000 weekly. In the parish of Cripplegate alone the disbursements to the poor amounted to £17,000 a week. But, even when the poor had obtained the money, they feared to lay it out in provisions, lest they should by this means catch the infection. If they bought a joint of meat in the market, they would not receive it from the butcher, but took it off the hooks themselves; the butcher, equally cautious, would not touch the money, but had it dropt into a pot with vinegar kept for the purpose. Workmen were equally cautious with their masters, and even members of the same family with each other.

The conduct of the magistracy, during the prevalence of calamity, did them infinite honor. Darwin has celebrated the heroic devotion of Sir John Lawrence, 'London's generous Mayor,' who,

When Contagion, with mephitic breath,
And wither'd Famine urg'd the work of death,
* * * * *

With food and faith, with med'cine and with prayer,
Rais'd the weak head, and stay'd the parting sigh;
Or with new life reum'd the swimming eye.

'The vigilance of the magistrates,' says the account ascribed to Defoe, 'was put to the utmost trial, and, it must be confessed, can never be enough acknowledged; whatever expense or trouble they were at, two things were never neglected in the city or suburbs either. First, provisions were always to be had in full plenty and the price not much raised either hardly worth speaking. Secondly, no dead bodies lay unburied, or uncovered; and, if one walked from one end of the city to another, no funeral, or sign of it, was to be seen in the day-time, except a little in the three first weeks in September.'

For the security of the country dealers by land, new markets were established on the outskirts of the metropolis, and proper regulations made to ensure the safety of those who attended them. Either the lord mayor, or one, or both of the sheriffs, went every market-day on horseback to see these orders executed. The necessitous were likewise furnished with food and money gratuitously, and the aldermen frequently rode through the streets on horseback, to enquire whether the wants of the people in the streets or houses were duly supplied.

In this year of desolation the most appalling scenes were continually occurring, which language would in vain attempt to depict. Many were the instances in which bodies were found stripped naked by thieves; and others, where the stupor of disease was mistaken for the sleep of death, and bodies yet warm and breathing were buried in the general mass. Tradition relates a narrow escape of a poor piper, which has been further immortalised by that great sculptor, Cibber, in a statue well known in

Tottenham Court Road. It represents a Highland piper playing on his pipes, with his dog and keg of liquor by his side. The piper, as the story goes, usually took his stand at the bottom of Holborn Hill, near St. Andrew's church, and, having one day met with some of his countrymen, he drank rather freely, and sought a couch on the steps of the church. As this was no time to sleep in the infected streets, when the dead cart arrived, one of the men did not hesitate to put his fork into the piper's belt, and transfer him to the cart. The piper's dog attempted to prevent his master from being carried off, but, unable to do this, he determined to accompany him, and, leaping into the cart, began howling most piteously over the body of his master. The shaking of the cart along the rugged pavement, and the howling of the dog, at length awoke the piper, who, instinctively turning to his pipes, struck up a lively Scotch tune, to the great terror of the carters, who fancied they had got a cargo of ghosts, until, lights having been procured, the piper was released, and his narrow escape was commemorated by one of his benefactors, who employed Cibber to execute a statue of him.

PART III.

DESCRIPTION OF MODERN LONDON.

This will embrace its site and climate; its rivers, canals, docks, and bridges; the tower and military defences; public buildings, civil, ecclesiastical, and charitable; streets, and squares; theatres and places of amusement; and the improvements in progress.

Situation and general plan.—The city of London stands entirely on the north bank of the Thames. St. Paul's is in lat. 51° 30' 49" N., and long. 5° 30' W. of Greenwich observatory. Its distance from the other capitals of Europe is, from Edinburgh 395 miles south; from Dublin 338 south-east; from Amsterdam 190 miles west; from Paris 225 miles N. N. W.; from Copenhagen 610 miles south-west; from Vienna 820 north-west; from Madrid 860 miles north-east by east; from Lisbon 850 miles; from Rome 950 miles N. N. W.; from Constantinople 1660 miles; from Moscow 1660 miles E. S. E.; from Stockholm 750 miles; from Petersburg 1140 miles; and from Berlin 540 miles.

The ancient city, or London within the walls, is about a mile and half in length, and something more than half a mile in breadth. During the last century its population has diminished nearly one-half; a circumstance to be attributed to the widening of the streets, to the many public buildings that have been erected, and to the general extension of its suburbs. London without the walls, being merely the expansion of the ancient city which it surrounds, is governed by the city magistrates.

The greater part of London stands upon rising ground; the soil is sound and dry; the lower parts are freed from moisture by subterraneous sewers or drains; and, from the vast quantities of water with which the inhabitants are constantly supplied, by means of the Thames and of the New River, great sweetness and cleanliness are preserved. The drains here mentioned are large

vaulted channels, beneath the pavements, communicating with each house by smaller ones, and with the respective streets by gratings, to carry off such as may be conveyed in that manner into the river. Mud, and other rubbish, are taken away in carts, by persons constantly employed for that purpose.

Considered in the aggregate, London comprises the city and its liberties, with the city and liberties of Westminster, the borough of Southwark, and nearly thirty of the contiguous villages of Middlesex and Surrey. The greatest portion of the whole is built on the northern bank of the Thames, or in Middlesex; whilst Southwark, with Lambeth, and several connecting villages, extend along the southern shore of the same river, in the county of Surrey. The extent east and west, from Poplar to Knightsbridge, is full seven miles and a half; while its breadth from north to south, or from Newington Butts to Islington, is nearly five miles. The circumference of the whole, allowing for various inequalities in the extension of streets, &c., at the extremities, is upwards of thirty miles. Hence it may be fairly estimated, that the buildings of this metropolis cover at least eighteen square miles, or 11,520 square acres. The river Thames occupies, for seven miles, a space of about one quarter of a mile, or 400 yards in width; or 1120 square acres.

This metropolis may be said to consist of five great parts or portions; viz. the west end of the town, the city, the east end of the town, Westminster, and the Borough. The west end of the town is popularly regarded as extending from Charing Cross to Hyde-park, and from St. James's park to Paddington. It is considered the superior and most fashionable part of the town, is the general abode of the court, and is laid out in two great thoroughfares, Oxford Road or Street, and Piccadilly and Regent Street; with various handsome squares and streets, chiefly occupied by the town houses of the nobility and gentry, and fashionable shops. The city includes the central part, and is the emporium of commerce.

The east of the town is also devoted to commerce, to ship-building, manufactures, and various collateral branches of merchandise; and here vast commercial docks and warehouses have been formed and constructed. The southern bank of the Thames, from Deptford to Lambeth, bears a great resemblance to the east end of the town; being occupied by persons engaged in commercial and maritime concerns; and docks, wharfs, and warehouses are abundant. This part of London abounds likewise with iron-foundries, glasshouses, soap-boilers, dye-houses, boat-builders, shot and hat manufactories, &c.

Southwark, a borough, once entirely independent of the city, but now forming the ward called Bridge Without, was, up to the reign of Edward III., so notoriously the resort of felons, robbers, and divers other malefactors, and disturbers of the peace, that the king, with the consent of the parliament, granted the city of London 'the said village with all its appurtenances,' for the sum of £10, to be paid annually. This grant, however, Richard, his successor, refused to con-

firm; and the corporation was unable, for several reigns, to establish its jurisdiction here. But, the privileges of the religious houses being at length renewed, the regents under Edward VI. (the great obstacle in their way), confirmed the complete annexation of the borough to the city by letters patent, dated 23d April, in the fourth year of that monarch's reign.

Many improvements have of late years been made, and many respectable houses erected in St. George's Fields. Hither also has been brought the Bethlem hospital for lunatics, formerly in Moorfields. Another part of the metropolis, the most regular and systematic of the whole in its arrangement, is the northern side, comprehending a large mass of new buildings between Holborn and Somers-town, and in the parishes of Mary-le-bone, and Paddington.

Amongst the many proofs of the early and extreme fondness for legislation which marks our history, may be mentioned the various laws which have been passed to prevent the growth of London. Queen Elizabeth led the way in this sage endeavour, and a statute of her reign commands (we believe it is not yet repealed), that 'persons of livelihood and means should reside in their countries, and not abide or sojourn in the city of London, so that countries remain unserved.' James I. predicted that 'England would shortly be London and London England;' and, in one of his numerous addresses to the people, stigmatises 'those swarms of gentry who, at the instigation of their wives, or to new-model and fashion their daughters (who if they were unmarried marred their reputations, and if married lost them), did neglect their country hospitality, and cumber the city, a general nuisance to the kingdom.' He urged the Star-chamber to regulate 'the exorbitancy of the new buildings about the city, which were but a shelter for those who, when they had spent their estates in coaches, lacqueys, and fine clothes, like Frenchmen, lived miserably in their houses like Italians.' A manuscript writer of the times complains of the breaking up of old family establishments, all crowding to 'upstart London.' 'Every one,' says he, 'strives to be a Diogenes in his house, and an emperor in the streets; not caring if they sleep in a tub, so they must be hurried in a coach, giving that allowance to horses and mares, that formerly maintained houses full of men; pinching many a belly to paint a few backs, and turning all the treasures of the kingdom into a few citizens' coffers, their woods into wardrobes, their leases into laces, and their goods and chattels into guarded coats and gaudy toys.'

The government, however, did not confine itself to mere fulminations on this subject; for new buildings were not only forbidden within ten miles of London, but even pulled down when they had been erected. Charles I. issued various proclamations, in which he complained of the continued residence of the nobility and gentry in town, which raised the price of provisions, increased the number of mendicants, and brought so many loose and disorderly people into the metropolis, that it could not be governed by ordinary magistrates. He ordered that persons of all ranks, who were not connected with

public offices, should resort to their several counties, and that 'they should not put themselves to unnecessary charge in providing themselves to return in winter to the said cities, as it was the king's firm resolution to withstand such great and growing evil.' Proclamations proving ineffectual, the Star-Chamber determined that they should no longer remain a dead letter; an inquisitorial examination of all strangers was ordered, and an account taken of their time of residence and departure. Prosecutions were instituted by the attorney-general; and one gentleman, a Mr. Palmer, from Sussex, was fined £1000 for disobeying the proclamation which ordered a residence in the country; and, to discourage all other gentlemen from living in town, the proclamation prohibited any pheasants, ducks, partridges, or hares, from being dressed or eaten in any inn. It is true, that these rigorous proceedings rendered the government obnoxious, and proved ineffectual; yet they were attempted to be renewed even after the Restoration.

What must the weak and tyrannical Stuarts have felt, had they, for the castigation of the country, continued to rule over us to the present times, when more houses are frequently built in a single year, than during the whole of their united reigns! It appears by the census of 1821, that London, including the borough of Southwark, contained the vast number of 161,905 houses, and that 3437 other houses were then building; and, when we consider that every month brings a large addition, it probably would not be too much to estimate the metropolis as containing at present 180,000 houses; nor are its limits, though the rage for building has been partially stopped, likely here to rest, according to present appearances.

Climate.—It would seem pretty well established that the climate of this country was in early times far more genial than at present. A writer of the thirteenth century tells us that a 'continued fall of showers throughout England for three days terrified many.' In ancient times, according to Mr. Bagford, there were vineyards in Hatton Garden, St. Giles, and East Smithfield; and the many Vine Streets in Westminster, Bloomsbury, Lambeth, and the borough, seem to have derived their name from the same source. This change, which the climate has undergone, appears to have chiefly taken place during the last century. Charles II., whose daily habits of walking about the metropolis gave him opportunities of correct observation on the subject, used to say, that there never was a day in which it rained so incessantly that a person could not take a dry walk for one hour out of the twenty-four.

The inhabitants of London, however, have less reason to complain of the deterioration of the climate than perhaps any other part of this country. We have noticed, *article ENGLAND*, the circumstance, not, perhaps, generally known, that the temperature of the air in the metropolis is raised by the artificial sources of heat existing in it, no less than 2° on the annual mean above that of its immediate vicinity; and the reader will there

find a table of the London temperature in the twelve different months of the year.

The usual range of the thermometer in London is from 5° to 95°. Even in the coldest seasons, however, the medium of the twenty-four hours, upon a long average, does not fall below the freezing point. Continued frost in winter is always an exception therefore to the general rule of the climate.

The most severe frosts of which we have any record were those of 1683, 1716, 1739, 1766, 1768, 1785, 1789, 1795, and 1814. Few of these, however, were peculiar to London; the greater number were, more or less, common to the whole of the north of Europe.

The frost of 1683, which is the first great one of which we have a particular account, appears to have been one of the most intense. The Thames was frozen to such an extent and depth, that even as far down as Woolwich the heaviest loaded carriages passed securely over it. From the Temple to Southwark it was covered with temporary shops and booths, arranged in streets and squares, where hackney-coaches plied as safely as on the terra firma of the metropolis. Shows and pastimes of all sorts diversified the scene; and the merry monarch himself, Charles II., mingled with his subjects in celebrating the novelty of a frost fair. In the night time the cold was so severe, that large fires were kept burning in Cheapside, Fleet Street, and other principal streets, to save from perishing those whose necessary avocations called them abroad; but notwithstanding this humane precaution, and the most commendable exertions on the part of the rich and benevolent to provide the poor with fuel at their own homes, many were the instances of persons in the lower walks of life being frozen to death. Wild ducks and other water fowl, driven from their native fastnesses to seek shelter in the haunts of men, dropped down dead in the public streets; and so general was the havoc among the feathered tribe, that in the ensuing summer scarcely a bird was to be seen. In other parts of Europe the cold was as severe as it was in England; particularly in Germany and France, where the number of human beings frozen to death appears to have been much greater than in England, owing, no doubt, to the inferior condition of the people of these countries, in all that regards the comforts and charities of life.

Next to the frost of 1683 in its disastrous consequences was that of 1739, which was also common to the whole of the north of Europe. The Thames was again completely frozen, but in a few days after so high a wind arose as to sweep every thing moveable from its surface. The number of the shipping in the river happened to be unusually great; and, locked up by the ice, they opposed a resistance to the fury of the wind, which made its ravages only the more destructive. Numbers were blown to pieces, and sunk; and all were, more or less, stripped and shattered. Never had the Thames, in the memory of those living, presented a more dismal scene of wreck and destruction. The damage done between London Bridge and the Medway was computed at not less than £100,000. Many

were the lives also lost upon this occasion; and severe the sufferings of the lower classes of people, although charity was again both active to save, and most liberal in its benefactions.

The frost of 1814 was, in some respects, even more memorable than those of 1683 and 1739. It was probably not so severe as either, and the injury which it committed was inconsiderable; but it served to exhibit in a remarkable manner the progress which a free people have made in those attainments, which help us to set the seasons themselves at defiance. As in the days of the gay Charles, mirth and jollity again joined hand in hand to soften the rigors of the icy year; but, among other novelties, we beheld what in Charles's days would have been more dreaded than even perpetual frost—a free press erected on the now solid deep, to commemorate the wonders of the scene.

River Thames.—The conservancy of the Thames belongs to the city of London westward as far as Staines, a little above which it enters the county of Middlesex. See THAMES. Nothing can be more picturesque than its now devious course towards the metropolis, graced with 'such fields, such woods, such stately piles, and such gardens,

That Thames with Roman Tiber may compare.'

At Putney and Battersea, the Thames, which has received the tributary streams of the Colne, the Wey, the Crane, the Brent, and the Wandle, has become a large and busy stream, and at these places is crossed by two wooden bridges. At Vauxhall it is crossed by a light and beautiful iron bridge, and between this place and the tower by four other bridges.

After running through the metropolis the river rolls onward past Deptford, Greenwich, and Gravesend, until, joined by the Medway, they pay their joint tribute to the ocean, at the Nore. In London it is from 800 to 1500 feet, and at the Nore seven miles broad. It is navigable nearly 143 miles above London Bridge: its whole length is upwards of 180 miles; and the tides, which ebb and flow twice every twenty-four hours, affect it upwards of eighty miles from the sea. The Thames has also its spring tides, and is remarkable for the inequality of its tides, a subject much dwelt upon by the early historians, who considered every deviation from the ordinary flow and ebb as a prodigy. It is related, that on the 12th of October, 1411, and on the 17th of September, 1550, the Thames flowed thrice in one day. In the years 1564, 1574, 1608, 1609, 1622, 1653, 1654, and 1660, similar phenomena occurred, all of which might, no doubt, have been traced to very natural causes had they been observed at the time.

The Thames has sometimes overflowed its banks considerably in the metropolis. The most memorable instance of this sort was on the 1st of September, 1555, when, in consequence of heavy rains and a high wind, the river was forced into the king's palace at Westminster, and into Westminster Hall, a circumstance particularly unfortunate, as it was the day on which the lord mayor of London had to present the sheriffs to the barons of the exchequer. Stowe says,

'all Westminster Hall was full of water,' but he does not inform us whether the city magistrates presented the sheriffs in a boat or not, though he informs us by report that morning, that, 'a wherrie man rowed with his boate over Westminster Bridge into the Palace Court, and so through the staple gate, and all the wooll staple into the king's streete.' All the marshes on the Lambeth sides were also so overflowed, that 'the people from Newington Church could not pass on foote, but were carried by boates from the said church to the Pinfold, neere to St. George's in Southwark.'

In 1774 was another great overflow; and again on the 2d of February, 1791, when considerable damage was done to the wharfs along both sides of the river. Westminster, which always suffered most from an inundation of the Thames, saw boats plying, instead of hackney coaches, in Palace Yard and Privy Gardens, like Egypt watered by an over-bountiful river.

In the winter of 1821 the Thames again burst its bounds; though neither promoted by an easterly wind, nor a sudden thaw. It appears by an official report presented by officers appointed to make a survey of the river, that the flood rose four inches higher than it did in 1774, as recorded by a stone let into a wall at Isleworth. The original editor of this work had on this occasion to pay a severe penalty for his general enjoyment of a very pleasant situation on the bank of the river. Its classic stream was not at this time 'strong without rage,' for it burst every barrier with which his cottage could be fenced; and flooding his library, to the depth of eighteen inches, scattered his papers remorselessly on the surface of six successive tides. Considerable damage was done above Westminster Bridge, yet the navigation of the river in the city district was never an hour impeded.

At Staines (Sax. *stana* a stone) is a stone which marks the limits of the city's authority, and bears the early date of 1280. During the mayoralty of Sir Watkin Lewes, in 1781, it was placed on a new pedestal. The city jurisdiction extends eastward to Yendal or Yenleet, and includes also part of the Medway and the river Lea.

The conservancy of the Thames has been claimed by the city of London ever since the reign of Richard I., who, for a sum of 1500 marks, granted a charter which empowered the city to remove all weirs from the river. The authority claimed under this charter was afterwards confirmed by more explicit enactments. The power of the citizens not merely extended to the water and the fish, but to the actual bed of the river, so that, according to a manuscript in the papers of lord Burleigh, quoted by Strype, they have the ground and soil under the river, 'whereupon if any that hath a house or land adjoining do make a strand, stairs, or such like, they pay forthwith a rent to the city of London.'

The authority of the city was long disputed by the lord high admiral of England, until the decision of a court of justice, and the confirmatory charter of James I., fixed the conservatorship of the Thames in the hands of the city, to be exercised by the lord mayor for the time being, or his deputy, an officer with the title of water bailiff,

who protects the rights of the city, and its authority over the river.

The lord mayor holds a court of conservancy eight times a year, at any place he pleases within the city jurisdiction, on the banks of the river, either in Middlesex, Surrey, Essex, or Kent. The jury attendant on the court is always summoned from the county in which it is held. In order to hold the court, the lord mayor, with the necessary officers, proceeds in state in the city barge, and is often accompanied by some of the barges of the companies, who render it an agreeable aquatic excursion. Once in every seven years his lordship traverses the whole limits of his jurisdiction on the Thames and the Medway.

A material part of the duty of the water bailiff is to regulate the watermen who ply on the river, and who are a very numerous body, amounting to upwards of 12,000, two-thirds of whom are freemen of the city. As far back as 1556, they were incorporated by act of parliament, and have their rulers and overseers; but the general government and superintendence of the body is vested in the city magistracy, who are empowered, by a statute passed in the 34th of George III., to make rules and orders for the government of watermen, wherry-men, and lightermen, between Gravesend and Windsor, and to enforce observance of them by penalties and forfeitures. The wherries belonging to this fraternity are required to be twelve feet and a half long, and four feet and a half broad in the midship; they are all numbered, and the rates of fare fixed, for any exaction beyond which the offender may be punished, on complaint being made at Watermen's Hall (on St. Mary's Hill). In point of fact, however, but little regard is paid to the established list of fares, which are very generally exceeded, and as generally acquiesced in, from a feeling, we believe, that they are rather less than they ought to be. Among other regulations for the good conduct of the watermen, they are particularly cautioned against the use of improper and immodest language; and offenders in this respect are punishable by fine. By an act of parliament of the 11th & 12th of William III. the lightermen were united to the watermen, and placed equally under the jurisdiction of the city magistrates.

The Thames westward has several locks, without which, owing to the great number of shoals, it would not be navigable in summer. The locks within the city's jurisdiction, according to a return made to an order of the house of commons, yielded to the city a revenue of £12,506 7s. 1d. for the year ending the 29th of September, 1822. Upwards of £1000 had, however, to be deducted for the incidental repairs. The profits of the locks have been a good deal injured by canals, yet the interests of the city have been protected; since we find, in the same parliamentary return, that the Grand Junction Canal Company paid to the city £600 for compensation for loss of toll that year; the Regent's Canal Company £450; and even the Surrey Iron Railway Company £10.

The immense property continually lying in shipping in the river Thames was long subject to the most daring depredation. The robbers

were indeed so numerous, that they were divided into classes. The river pirates formed the most desperate class. They plundered ships and small craft in the night; and have been known to weigh a ship's anchor, and hoist it with the cable into the boat; and when discovered, to tell the captain what they had robbed him of, and row away bidding him a good night. The night plunderers consisted of watchmen, who, formed into gangs of five or six each, used to lighten every vessel they could get to of some portable articles of her cargo, while a receiver was always in readiness to purchase the spoils of the night. These night plunderers have frequently been known to cut lighters adrift, and follow them down the river, to a place where they could more successfully carry off the cargo, which they have sometimes done completely. The light horsemen confined their depredations to West India ships, and originated in the connivance of the revenue officers at a connexion established between the mates of the vessels and some receivers on shore. In all West India ships there is a quantity of sugar spilt in unloading the cargo, which is claimed as a perquisite by the mates, and sold. The purchasers of these sweepings, however, by a bribe of forty or fifty guineas, often succeeded in getting on board the ships, and opening the hogsheads and taking as much as they could, by the assistance of coopers and watermen, carry away with them. They were provided with black bags, which they called black strap, and these were often filled and emptied during a night. Puncheons of rum were also drawn by means of a small pump. The heavy horsemen, another class of river plunderers, went on board ships, either by connivance, or in the day, under the pretext of selling some articles. They were provided with peculiar dresses, which had pockets all round, and bag bladders and pouches affixed in various parts, which they filled with sugar, coffee, cocoa, or any portable articles they could lay their hands on. In the night they would frequently plunder more largely, and boats, rowed by what were called game watermen, were constantly near the ships, ready to receive the stolen property and conduct them on shore. So active were the heavy horsemen, that they frequently made five guineas a night, and an apprentice to the game waterman has been known to keep a country house and a saddle horse. The mud larks, the scuffle hunters, the copemen, and several other classes of depredators, were not confined to any particular branch of plunder, but were ready, either as principals or auxiliaries on all occasions.

The coal-heavers, of whom there were 1200 or 1400 constantly engaged on the river, were in the constant practice of each man taking his sack of two or three bushels of coals when he went on shore during the unloading of a ship. Neither the captain nor the owner of the ship and cargo durst resist their taking what they considered as a perquisite, and when they found a boat ready to sink with their plunder, they conceived themselves the injured party.

Some idea may be formed of the success of these plunderers, when it is stated, that the loss of various classes of property on the river, pre-

vious to the formation of the docks and the establishment of marine police, was £500,000 annually, of which, according to an averaged estimate of some years, the West India trade suffered annually to the amount of £232,000; the East Indies, £25,000; the United States, £30,000; and the coal trade alone, £20,000.

Such was the state of the cargoes in the river Thames, until, in the year 1797, Mr. Harriott formed a plan of marine police, which, by the aid of Mr. Colquhoun, he was enabled to carry into effect; and so successful was the system thus formed that in the first year the saving to the West India merchants alone was upwards of £100,000, and to the revenue more than half that sum. In the same period, no less than 2200 culprits were convicted for misdemeanors on the river; while now the instances of street robberies are so rare, or so unimportant, that they are scarcely ever recorded.

Various amusements have at different times taken place on the Thames, adapted to the taste and character of the age. The water quintain has, however, altogether ceased, and at present rowing and sailing matches seem the only sports with which it is occupied. Of these, one of the most remarkable is the competition for a coat and silver badge, which Dogget the player appointed to be rowed for, annually, by six watermen, on the 1st of August, being the anniversary of the accession of the House of Hanover to the throne. The competitors set out on a signal given, at that time of the tide when the current is strongest against them, and row from the Old Swan, near London Bridge, to the White Swan, in Chelsea.

Smaller rivers and supply of water.—Nothing has contributed so essentially towards preserving the health of the inhabitants of London from disease, or their property from conflagration, as the abundant supply of water with which every street, and even every house, is furnished. Before the metropolis had become extensive, it was watered by several small brooks, independent of the Thames. One of these, which was successively called the river of Wells, Turnmill Brook, and the river Fleete, or Fleet Ditch, ran from Bagnigge Wells, through Clerkenwell, between Saffron Hill and Turnmill Street, under Holborn Bridge, and down Fleet Market into the Thames. It was once very considerable, turned a great number of mills in its course, and must have been navigable from the Thames to Holborn at the least; for, in a parliament, held at Carlisle in 1307, the earl of Lincoln complained, that ‘whereas, in times past, the course of water running at London under Oldbourn-bridge and Fleet-bridge into the Thames, had been of such breadth and depth, that ten or twelve ships’ navies at once, with merchandizes, were wont to come to the aforesaid bridge of Fleet, and some of them to Oldbourn Bridge; now the same course, by filth of the tanners and such others, was sore decayed.’ Tradition would carry the navigation much higher, since it relates, that an anchor was found in this river at Pancras-wash, where the road branches off to Somer’s-town. This river is now, by rapid rains or sudden thaws, sometimes much overflowed, as was the case in 1809 and 1817-18.

Another small river, called *Wallbrook*, from the wall thrown over it, ran through the city in a serpentine direction, from the north down by the present Mansion House, and the street now called Wallbrook, into the Thames. This brook, which was necessarily crossed by numerous bridges, was vaulted over with brick, and in many parts covered with houses.

A third rivulet, which was called Langbourn, on account of its length, originated in an overflowing spring in Fenchurch Street, which ran down Lombard Street, and turned south down Sherbone Lane (then called Sharebourne, from its sharing or dividing the bourne or brook into small rills of water), whence it flowed into the Thames. This brook was stopped at the source, though its name is still retained in Langbournward.

Oldbourn, now Holborn, was a brook which issued from a spring near Middle Row, and ran down at Holborn Bridge, into the river Fleet.

In the suburbs were several very excellent wells, as Holywell, Skinner’s-well, Clement’s-well, Clerkenwell (so called from the parish-clerks of London assembling there annually to act plays or interludes, founded on Scripture), with several other smaller wells. To the wells and the brooks are to be added pools, which, though not contributing to the health of the city, supplied water for various uses. Of these the principal was in Smithfield, and was called Horsepool, on account of the inhabitants watering horses there. This pool, which was at one time walled round with brick, was filled up in the improvements that took place in Smithfield after the fire of London. Near St. Giles’s church, Cripplegate, there was a large pool, in which Anne of Lodbury was drowned in the year 1244. North of Holywell there was a pool, called Agnes le Clair; and, not far from it, another sheet of water, which was called Perilous Pond, on account of several youths who went to swim in it having been drowned. This Perilous Pond has since been converted into a bath, under the name of Peerless Pool.

The pools being filled up, and the brooks covered, the inhabitants found it necessary to look to other sources, for a supply of water. In 1236 one Gilbert Sandford obtained a grant from Henry III., to allow him to convey water from the town of Tyburn, by pipes of lead, into the city. The work was soon carried into effect, and a leaden pipe, of six inches bore, conveyed the water, from six wells in the neighbourhood of Tyburn, to conduits that were erected to receive it in various parts of the city. The first, and one of the principal conduits, was in West Cheap, now Cheapside, and was erected in 1285: it was a cistern of lead, castellated with stone. Other conduits and bosses were erected in several parts of the town.

In 1438 Sir William Eastfield, knight of the Bath, then lord-mayor, brought water from Highbury Barn, as well as from Tyburn, to London, and caused conduits to be erected in Fleet Street, Aldermanbury, and Cripplegate.

In 1535 the common council granted a sum of money for bringing water from Hackney to Aldgate, where a conduit was erected; and,

this being insufficient, fresh supplies were afterwards obtained from St. Mary-le-bourn, Hackney, Hampstead Heath, Muswell Hill, &c. One of the principal conduits was between Snow Hill and Holborn, and was built, or rather rebuilt, by William Lamb, a gentleman of the chapel to king Henry VIII. in 1577, at an expense of £1500. This conduit was supplied from another, erected by the same gentleman at the north end of Red-Lion Street, called Lamb's Conduit.

The conduits were formerly visited and inspected, with great ceremony, by the lord mayor and corporation. Strype relates, that, on the 18th of September 1562, the lord mayor, aldermen, and many worshipful persons, after inspecting the conduit heads, hunted a hare, which they killed, and then proceeded to a dinner at the head of the conduit, where they were handsomely entertained by the chamberlain. After dinner they went to hunt the fox: 'there was,' says he, 'a great cry for a mile, and, at length, the hounds killed him at the end of St. Giles's, with great hallowing and blowing of horns at his death.' But, though the number of conduits was considerable, they were found insufficient, and many citizens were obliged to fetch their water from the Thames. In those times, persons were regularly employed to convey water from the river, or the conduits, to the houses, which they did in vessels, called tankards, that held about three gallons. They were hooped round, like a pail, and were, in figure, like the frustum of a cone. They had a small iron handle at the upper end, like an alehouse pot, and, being fitted with a bung or stopple, were easily portable. These water-bearers and their tankards are alluded to in Ben Jonson's comedy of 'Every Man in his Humor.'

In the year 1582 one Peter Maurice, a German, proposed to supply the city with water by means of machinery. In order to prove his skill, Maurice made an experiment before the lord mayor and aldermen, by throwing the water over the steeple of St. Magnus's church, with which they were so much pleased that they granted him the use of the Thames water, and one arch of London Bridge, on lease for 500 years, on condition of paying 10s. yearly to the city. He then erected his water-works on the north side of the river; and, finding that he had not room enough, he procured, two years afterwards, the grant of another arch of the bridge for a similar term. By these works, which supplied a considerable portion of the east of the city, Maurice and his descendants made a large fortune. In the year 1701 the proprietor sold his right in the London Bridge water-works for £38,000 to Richard Soams; who, obtaining a renewal of the leases from the city, and the liberty of occupying two more arches of the bridge, divided the property into 300 shares of £500 each, an operation by which he made a clear profit of above £100,000.

During the reigns of queen Elizabeth and king James I. acts of parliament were granted for the better supplying of the metropolis with water; but they were not carried into effect, until Mr. Hugh Middleton, a native of Denbigh, and goldsmith of London, undertook to bring the water

from Chadwell and Amwell, near Ware in Hertfordshire, a distance of upwards of twenty miles. The work was begun on the 28th of February, 1608, and concluded in five years. The course of the river extends about thirty-nine miles, being in a serpentine direction, and there are upwards of 200 bridges over it. The great reservoir, called the New-River Head, is at Islington, into which the water was first let in, on Michaelmas day 1613, the day on which Sir Thomas Middleton, the brother of Sir Hugh, was elected mayor. On the opening of the basin, the lord mayor, the lord mayor elect, the aldermen, &c., rode to see it; when a company of sixty laborers, well and uniformly clothed, preceded by drums, and accoutred with spades, shovels, and pick-axes, marched twice or thrice round the cistern, and then presented themselves before the visitors, when one of the workmen delivered an address, written for the occasion, which thus concluded:—

Now for the fruits; then flow forth, precious spring,

So long and dearly sought for, and now bring
Comfort to all that love thee! Loudly sing,
And with thy crystal murmurs struck together,
Bid all thy true well-wishers welcome hither.

At the conclusion of these words, 'the flood-gate flew open, and the stream ran swiftly into the cistern, with drums and trumpets sounding, and guns firing in a triumphant manner.'

The main pipes of the New River company were originally of wood, but they are now almost entirely of cast iron. A large basin has been constructed in the Hampstead-road, which receives its water from Islington, in order to supply the western parts of the town. The number of houses supplied by the New River is upwards of 56,000, which is continually increasing, particularly since the water-works have been recently taken down at London Bridge.

The New River was, however, long an unprofitable speculation, and, for nineteen years after it was finished, the seventy-two shares, into which it was divided, did not yield a profit of more than 12s. each. These shares, in the course of time, were sold as high as £14,000 each; and although, at the present moment, they are unproductive, in consequence of the great expense incurred in substituting iron for wooden pipes, yet they are considered valuable. As for the projector of this great work, his only reward was a ruined fortune, and a barren title. Mr. Middleton was created a baronet, and there is an entry in one of the Cottonian MSS. in the British Museum, stating, that the fees of the creation were to be remitted to him.

There are several other water companies in London and its suburbs, the relative importance of which will be seen from the quantity of water supplied by each, which we are enabled to collect from the evidence adduced before a committee of the house of commons in 1821.

In 1808 and 1809 the New River, on an average of the two years, supplied London with 78,110,000 hhdls., or 4,217,940,000 galls. of water annually, to 59,058 houses and buildings, occupied by 42,960 tenants, who paid an annual

rental to the company of £80,782. In 1820 the New River, including the York Building water-works, established in the reign of Charles II., supplied 67,000,000 hhd. to 52,082 houses, and 38,535 tenants, on a rental of £68,297.

In the same year the Chelsea water-works, which were formed in 1721, supplied 7,533,900 hhd.; the London Bridge works 26,322,705; the East London works 29,516,333; the Grand Junction water company 13,104,100; and the West Middlesex works 11,904,000. These form an aggregate, in the year 1820, of 155,381,038 hhd. of water, supplied to 120,732 houses, and yielding a rental of £175,890 annually. So effective is the machinery of these water-works, that they can force water into the rooms of every house, to the height of 100 feet if required.

The docks.—Connected both with the commerce of the metropolis and the river is the establishment of closed docks, which have been of the most decided service to the revenue and trade of the country—to quote the words of the report of the parliamentary committee on the West India docks, in June 1823, ‘the value of these institutions, whether in giving facility to commerce, in securing the collection of the revenue, or in protecting the interests of the merchants, is so unquestionable, that it would be an unnecessary waste of time to enter into any detailed discussion on the subject.’

The insecurity in which the property of the river was placed, and the daring plunder committed on it, which has already been noticed, no doubt first led to the formation of the commercial docks. The most important of these are the East India, the West India, and the London docks; there is also the East Country dock at Rotherhithe, near the king’s victualling-office, which is appropriated to the Baltic and American trade, the fisheries, &c. It will contain eighty ships.

The West India docks are situated in that peninsular part of the environs of London called the Isle of Dogs, and they communicate with the Thames at Limehouse on the west, and at Blackwall on the east. They were commenced on the 12th of June 1800, and finished in August 1802. The docks, and the ground belonging to them, occupy an area of 204 acres. The dock for unloading inwards is 2600 feet long, 510 wide, and twenty-nine feet deep; it is built round with brick-work five feet thick: the dock for loading outwards is similarly constructed, and of the same dimensions except in the width, which is only 400 feet narrower than the other. The entrance basin at Blackwall, which communicates by means of two locks with the import and export docks, occupies a space of six acres: the basin on the Limehouse side, which also has a communication with both docks, is somewhat smaller. The warehouses which surround the docks are necessarily of immense magnitude, and they are built in a style of neatness that would render them an ornament to any part of the metropolis. The expense of these docks, which have rendered an inestimable service to its trade, was £1,200,000.

During the construction of these docks, the ballast which formed a barrier between the dock

and the Thames was driven away, and, the water rushing in from the river, several persons were killed. The largest dock was completed and opened for the reception of the water on the 3d of August 1802; and such is the extent of this artificial lake, that, although the water flowed in at the rate of from 500 to 1000 gallons in a second, yet the great dock was not completely filled a sufficient depth until six o’clock the next morning, being ten hours. On the 3d of September the grand ceremony of receiving the first ship took place, when the Henry Addington, a new-built West India vessel of 350 tons burden, was towed in by ropes amidst the cheers of at least 10,000 spectators.

The proprietors of the West India docks are an incorporated body, under the title of the West India Dock Company, and they are reimbursed by a tonnage on the vessels that enter the docks, and a per centage for landing, weighing, and warehousing the cargoes. Near the docks is a school, established by the company for the accommodation and instruction of apprentices in the West India trade during the time that the vessels are in dock. The boys are taught reading, writing, and arithmetic, and the elementary principles of mathematics and navigation.

Parallel with the docks there is a canal, which enables vessels to save a distance of a mile and three quarters by avoiding the circuitous navigation round the Isle of Dogs. This canal, which is three quarters of a mile in length, and 200 feet in width, was cut pursuant to an act of parliament passed in 1799, at an expense of £133,849 12s. 6d. For the first three years after it was formed a small duty was charged on all vessels that passed through it.

The East India docks are farther down the river than the West India docks, though at no great distance from them: they consist also of an import and an export dock; the former, covering an area of eighteen acres and a half, is 1410 feet long, 560 wide, and thirty feet deep; the latter, which is of equal depth, is 780 feet long, 520 wide, and covers a space of nine acres and a half. The entrance basin occupies an area of two acres and three quarters. The largest dock is sufficiently capacious to admit at the same time twenty-eight East Indiamen, with double that number of smaller vessels. When the goods are landed, they are conveyed along the East India dock and Commercial Roads to the company’s warehouses in covered waggon, which are well secured against all depredations.

The London dock, situated in the parish of St. John, Wapping, was formed for the same purpose as the East and West India docks—the facilitating the unloading of vessels, and the safe custody of the cargoes. This dock, which is not confined to any particular branch of commerce, is 1262 feet long by 699 wide, and in depth twenty-nine feet. It is capable of containing 200 sail of merchantmen, and was constructed at an expense of £1,200,000. The dock, which is entered through a basin, opposite Wapping Old Stairs, capable of containing several sail, was opened on the 1st of February 1805, when the *Perseverance* of Liverpool, the oldest vessel in the Oporto trade, decorated with the flags of all

...ions, not excepting the French, with whom we were at war, sailed majestically into the dock, which is nearly surrounded by a quay of 100 feet in width. The warehouses are immense, particularly two appropriated to the reception of tobacco, which are under the direction of the officers of the customs. One of these warehouses is 762 feet long and 160 wide; the other 250 feet long and 200 wide. Underneath these warehouses are cellars, in which there are seldom less than 7000 pipes of wine. The London dock water is said to be very injurious to health, and the verdigris generated here will act as a poison on the stomach. In addition to the basins here mentioned, is St. Katherine's dock, close to the Tower, where vessels of 800 tons burden have often been admitted; and on the south side of the river are the Greenland or Commercial Docks, and those connected with Surrey navigation.

THE BRIDGES.—At what period a bridge was first thrown over the Thames, between *London and Southwark*, seems doubtful. The first notice we have of its existence occurs in the laws of Ethelred II., which fix the tolls to be paid on all vessels coming up to the bridge. William of Malmesbury also mentions this bridge, in his account of the sieges which the city sustained on the invasion of England by the Danes, under Sweyn and Canute. That the bridge was erected between the years 993 and 1016 is inferred from the circumstance, that in the former year, Unlaf the Dane is said to have sailed much higher up the river; and that, in the latter year, Canute's progress was impeded by it.

The first bridge, which consisted entirely of timber, was not, as Stowe affirms, constructed by the convent of St. Mary Overy, but at the public expense, and in a different place from the present one, as we learn from a charter of William the Conqueror to Westminster Abbey, which mentions it as directly opposite to St. Botolph's gate and wharf. The bridge was burnt in 1136, but not totally destroyed; it was repaired, but decayed so rapidly, that in the year 1163 it was taken down, and entirely rebuilt of timber. The expense of keeping it in repair was, however, so great, that in 1176 a new one of stone was begun to be erected on the present site. The most active promoter and superintendent of this building was a priest, called Peter of Colechurch, who was well skilled in architecture, and who has hence acquired the credit of being its founder; but the king, Henry II., the archbishop of Canterbury, and several merchants of London, contributed largely to it. The aid granted by Henry II. to the bridge was in the form of a tax on wool, levied for the purpose; and hence arose a vulgar tradition, that 'London-bridge was built on woolpacks.' It was constructed on piles, principally of elm, which have remained for six centuries without material decay. On the piles, long beams of timber, ten inches thick, were placed, strongly bolted together, and the lowermost stones were embedded in pitch, in order to resist the water.

In 1202 king John appointed Isenbert of Xainctes to finish the bridge, Peter of Colechurch being either dead or incapacitated from

attending to it. The same monarch gave the profits and rents of several plots of ground, sold or let for building, towards the building and repairing of the bridge; and, during the same reign, the master mason built a large chapel on the centre arch, at his own expense, which was dedicated to St. Thomas à Becket.

The erection of chapels on bridges is of the highest antiquity, and, no doubt, originated from the custom of making sacrifices on bridges, whence Plutarch has derived the word Pontifex. The most remarkable bridge of this sort was at Droitwich, where the high road passed through the chapel, and divided the congregation from the reading-desk and pulpit. The priests attached to the chapels were commissioned, as an indispensable part of their office, to keep the bridge in repair; and hence, although Stowe is wrong in stating, that London Bridge was built by the priests of St. Mary Overy, it is not improbable that they were enjoined to repair it, in accordance with the ancient custom. The chapel on London Bridge was at first endowed for two priests and four clerks, and in the reign of Henry VI. it maintained four chaplains.

Four years after the bridge was finished, it was the scene of a very tragical accident. In the night of the 10th of July, 1213, a fire broke out in Southwark; when the bridge became crowded with people, all hastening from the city, either to witness or extinguish the conflagration. The flames, catching St. Mary Overy's church, were, by a strong southerly wind, extended to the Southwark end of the bridge: those who were foremost in the advancing throng endeavoured, but vainly, to fall back from the destroying element; the multitude on the London side, ignorant of the danger, continued to press unyieldingly forward, and, in this tumultuous conflict, numbers were trampled to death; others leaped into the river, to find only a watery grave; while many more perished miserably in the flames. Not less than 3000 lives are stated to have been lost on the occasion. It is supposed, that at this period the only building on the bridge was the chapel of St. Thomas à Becket; nay, it has been said, that even as late as 1395, 'the bridge, at that time, was only coped on each side, and not replenished with houses.' (Seymour and Marchant). That, at least, the last statement is erroneous, is, however, quite certain; for among the records, preserved in the tower, there are letters patent of Edward I., by which, in 1280, he authorises a collection to be made throughout the realm, for the repair of London Bridge, which is there described to be in such a ruinous condition, that 'unless speedy remedy be put, not only the sudden fall of the bridge, but also the destruction of innumerable people dwelling on it, may suddenly be feared.'

The subscriptions obtained under the letters patent of Edward I. being found inadequate to the execution of the repairs wanted, Edward, in 1281, ordered a toll to be levied, during three years, on all persons crossing the bridge with merchandise, and on 'every saleable pack.'

Whenever it was necessary for the sovereign to cross the bridge, he was treated with great magnificence by the citizens. Richard II. and

his young queen, Anne of Bohemia, were met by the citizens 'at the gate of the brigg of London,' says an old chronicler, 'where they presented him with a mylk-white stede, saddled and bridled, and trapped with cloth of gold and rede parted togedre; and the quene, a palfry all white, and in the same way trapped with white and rede, while all the condites were rounen with wyne, bothe whyte and rede, for all maner of peple to drynke of.'

In 1282, on the breaking up of the river after a great frost, five arches of the bridge were carried away; and, though these appear to have been immediately restored, yet in 1289 the bridge was again so much decayed, that people were afraid to pass over it. A new collection was, therefore, made throughout the kingdom for its repair, and that yielding, as before, but little, it was found necessary, in 1298, to revive the toll on goods and passengers.

The bridge was now so encumbered with houses, that the broad way between them did not exceed twelve feet in breadth; yet it appears to have been employed as a sort of joint mart for the inhabitants of the city and those of the borough. The first order of common council upon record is one of 1277, prohibiting 'any market from being held on London Bridge.' What had been a theatre for the quarrels of costermongers, became afterwards the chosen spot of jousts of a higher order. On St. George's day, 1395, there was a grand jousting match upon London Bridge, at which the lord Wells engaged to maintain the renown of England against all comers. A stout Scotsman, David, earl of Crawford, entered the lists, and at the third course, threw the English champion out of his saddle.

In 1471, when Falconbridge was repulsed in his attempt to seize the city, several houses on the bridge were burnt down by the disappointed invaders. The next remarkable conflagration took place in 1632, when forty houses were destroyed. The Thames being frozen over at the time, water could not be obtained, and the fire continued burning in the vaults and cellars upwards of a week. All the houses destroyed on this occasion had not been replaced, when the great fire of 1666 caused a still greater devastation.

Amidst the general improvements for which that calamity paved the way, the bridge was not neglected. The whole of the houses, from one end to the other, were taken down, with the exception of one house at the north end, which had been constructed in Holland, and was called the Tower of London Bridge, or the Nonsuch, from its not having a single nail in it, but being pinned together with wooden pegs. New ones were erected of a uniform breadth and elevation; and three vacancies left at equal distances, from which a view of the river might be obtained. The Nonsuch occupying the whole breadth of the bridge, the archway under it was raised to the height of two stories, and over it the following inscription was placed:—

Anno MDCLXXXV., et primo Jacobi II. Regis.

This street was opened and enlarged from twelve to the width of twenty feet.

Sir James Smith, knight, Lord Mayor.

The bridge itself consisted, as at present, of nineteen arches, the highest of which rises sixty feet above the water level.

The three widest of these arches used to be called The Navigable Locks, from their being the only ones which afforded an easy passage for vessels. The one nearest to the London side was particularly distinguished by the name of the Rock Lock, in consequence of a strange imagination among the vulgar, that there was a growing or vegetating species of rock beneath the water at this spot. It appears, from many subsequent observations, that this growing rock was nothing more than a collection of fallen materials; some former arch or coping—which, by serving as a nucleus for the deposits of millions of tides, has given rise to the popular and metaphorical notion.

The arch nearest of all to the London side was formed of a drawbridge; and, as late as 1722, such were the ideas which then prevailed of the means by which the invasion of enemies is best resisted, that the corporation did not grudge the expense of laying down a new one, nor the public the interruption occasioned by this idle project for adding to the security of the capital.

Besides the Nonsuch Tower at the city end of the bridge, there was another at the Southwark end, and to each there were gates with posterns for foot passengers. It was on the last of these towers that the heads of traitors in later times were exposed, when the citizens of London, falling into a distaste for such marks of civilisation, chose to remove them from their own end of the bridge. As late as 1598 Hentzner, the German traveller, relates, that he counted on it above thirty heads.

In 1756 an act of parliament was obtained for improving the bridge, and a temporary wooden bridge was constructed while the repairs were going on; but, with the fate common to wooden bridges, the latter was destroyed by fire the 11th April, 1759. The two centre arches of the stone bridge were now thrown into one; and the remaining houses, which were principally occupied by pin and needle makers, were taken down, and the bridge put into that state in which it now appears.

On the opening of the great arch, the excavation around and under the starlings was so considerable, that the bridge was thought to be in great danger of falling. Mr. Smeaton, the engineer, was then in Yorkshire, but an express was sent for him, and he arrived with the utmost despatch; when the apprehensions of the bridge falling were so general, that few persons would pass over or under it. Mr. Smeaton having ascertained the state of the starlings, and called the committee together, recommended that they should re-purchase the stones that had been taken from the middle pier, then lying on Moorfields, and throw them into the river to guard the starlings. Nothing shows the fears entertained for the stability of the bridge more than the alacrity with which his advice was adopted. The stones were re-purchased that day, and on the following morning the work commenced, which in all probability preserved the bridge from falling, and secured it until more effectual methods could be

taken. This famous old bridge, with the history of which that of London is so intimately connected, has been wholly removed, and a noble bridge of five arches, of granite stone, erected near the same site. The new London bridge was opened to the public on the 1st of August, 1831.

London Bridge is the greatest thoroughfare across the river. In one day in July, 1811, 39,640 foot passengers, 769 wagons, 2924 carts and drays, 1240 coaches, 485 gigs and taxed carts, and 764 horses, passed over it.

It is in no small degree surprising that a city like London, which had grown to such magnitude and opulence, and extended for miles along both banks of a mighty stream, should, till so late a period as the middle of last century, have had but one bridge across the river. It makes probable a statement of Strype's, which seems at first sight very exaggerated, namely, that in his time there were no less than 40,000 watermen upon the rolls of the watermen's company; now they do not much exceed 2000. The great inconvenience which the inhabitants of *Westminster* suffered from the want of a bridge at that end of the metropolis, led them at length, in 1734, to apply to parliament for powers to erect one from New Palace Yard to the opposite shore in the county of Surrey. Strong opposition was made to the measure by the city, the inhabitants of Southwark, the watermen, and the west country bargemen, who were all liable to suffer in their peculiar interests by such an erection; but the interest of the public very properly prevailed, and the act was granted. The first stone of the bridge was laid on the 29th of January, 1738-9, by Henry, earl of Pembroke, and the last on the 10th of November, 1750, by Thomas Lediard, esq. It is from wharf to wharf about 1223 feet long; the width is about forty feet, and on each side there is a high balustrade of stone, with semi-octangular alcoves, to serve as places of shelter from the rain. The free water way under the arches extends to 870 feet; the arches are fifteen in number; the centre one is seventy-six feet wide; the others diminish in width by four feet equally on each side; the two smallest ones close in shore to the abutments are each about twenty-five feet wide. The whole edifice is of stone, and rests upon a gravel bed, the piers having been sunk for that purpose to from five to fourteen feet under the bed of the river. When the work was nearly finished, in consequence of the incautious removal of some gravel from the bed of the river, immediately joining one of the piers, it sunk so far as to damage the incumbent arch to such a degree, that it was thought proper to have it pulled down and rebuilt. But for this interruption, the bridge would have been finished three years earlier. The total expense of the bridge, which was defrayed by parliament, amounted to £389,500. The architect was an ingenious Frenchman of the name of Labelee.

While Westminster Bridge had no rival but that of London, or only Blackfriars, it was esteemed one of the noblest structures of the kind in the known world; but since the erection near it of Waterloo Bridge, it seems to have lost

much of the grandeur which it possessed; and, although not a century old, it has suffered greatly from the decomposition of its stone.

When a person whispers against the wall of any of the alcoves of this bridge, the sound is very distinctly conveyed across to the corresponding alcove on the opposite side, notwithstanding all the noise occasioned by the passing of carriages, &c.

Blackfriars, originally called *Pitt's Bridge*, was begun in 1760, and occupied nine years in its erection. 'On the last day of October,' says an inscription on a tin plate on the foundation stone of the edifice, 'in the year 1760, and in the beginning of the most auspicious reign of George III., Sir Thomas Chitty, knight, lord mayor, laid the first stone of this bridge, undertaken by the common council of London (in the height of an expensive war), for the public accommodation and ornament of the city; Robert Mylne being the architect; and that there may remain to posterity a monument of this city's affection to the man, who by the strength of his genius, the steadiness of his mind, and a kind of happy contagion of his probity and spirit (under the divine favor and fortunate auspices of George II.) recovered, augmented, and secured the British empire in Asia, Africa, and America, and restored the ancient reputation and influence of his country among the nations of Europe; the citizens of London have unanimously voted this bridge to be inscribed with the name of William Pitt.' How evanescent a thing is this city affection! Of all the thousands who now pass this bridge daily, how few are aware of the fact which this inscription records! The compliment which the citizens of 1760 unanimously voted, the citizens of later times have refused to confirm, and Pitt's bridge is now styled, beyond all hope of alteration, *Blackfriars*.

The expense of this bridge was small when compared with that of Westminster, and still more with other bridges erected at a later period. The total cost was only £260,000, which was all defrayed by a toll imposed on passengers for several years. Blackfriars bridge is shorter and not so high as Westminster, but the differences are not so great as to account for the latter having cost above £100,000 more. The length of this bridge from wharf to wharf is 995 feet; and its width forty-two. It has nine elliptical arches, the centre one of which is 100 feet wide. Over each pier there is a square recess, supported by Ionic pillars and pilasters, which have a very light and ornamental effect on the appearance of the bridge, when viewed from the river. Blackfriars, unlike Westminster Bridge, rests on piles driven under water, and cut off level with the bed of the foundations, by a machinery of Mr. Mylne the architect's invention.

The erection of this bridge was attended with corresponding improvements of great importance to the adjacent parts of the metropolis. What is now called Bridge Street, one of the most spacious and elegant in the metropolis, was of old the channel of one of its greatest nuisances, and thicker, as to the veriest sink in town, has Pope made the genius of Dulness dismiss her children:—

— By Bridewell all descend,
 (As morning prayer and flagellation end),
 To where Fleet ditch, with disemboing streams,
 Rolls the large tribute of dead dogs to Thames;
 The king of Dykes! than whom no sluice of mud
 With deeper sable blots the silver flood.

In 1734 and 1737 this ditch had been arched over as far as the obelisk at the commencement of the present Bridge Street; and the arching being now continued onward to the bridge, every visible trace of the 'sluice of mud' was removed. Altogether, this forms by far the finest entrance into the metropolis. When a stranger ascends the bridge, the views of the city which burst upon him on either hand are singularly grand and picturesque. Before him, on the right, he beholds the mighty dome of St. Paul's, and beyond it spires and turrets thickening into a very forest towards the east; on the right, the lofty terraces of Somerset House and the Adelphi, Westminster Abbey's venerable towers, and Waterloo, the first of bridges. As the opening of this bridge entirely ruined a Sunday ferry, established at this place for the benefit of the poor of the fraternity of watermen, the bridge committee very handsomely agreed to transfer £13,650 consolidated 3 per cents. to the rulers of the company by way of recompense for the loss: the interest of which is now appropriated to the same uses as the profits which were derived from the ferry.

To defray the expense of lighting, watching, cleansing, and repairing this bridge, there is a particular fund set apart, consisting of a small balance of consolidated 3 per cent. annuities, left after payment of the expense of erecting the bridge, the rent of some premises, and £15,000 raised by bonds in the credit of the Orphan's Fund, by virtue of an act of the 52 Geo. III., and assigned to the chamberlain for this special purpose. The revenue of this fund in the year 1821-2 was £882 12s. 10½d.; the expenditure only £522 16s. 6d.

It has been well observed, of *Waterloo Bridge*, that it is 'a work not less pre-eminent among the bridges of all ages and countries, than the event which it will commemorate is unrivalled in the annals of ancient or modern history.' The celebrated Canova, when on a visit to this country, declared that it was worth a journey from the remotest corner of the earth to behold it. M. Dupin, another intelligent foreigner, describes it as a monument worthy of the Sesostrises and the Cæsars. The original projector of this bridge was Mr. George Dodd; but quarrelling with the company, who subscribed the capital to carry the plan into effect, he was put aside as soon as real business commenced, and the execution of the work confided to Mr. Rennie. It was at first proposed that it should be of wood, and that with the profits arising from a toll on this bridge, which were expected to be immense, one of stone should be afterwards erected; but, after struggling for three sessions to carry a bill to this effect through parliament, the company found the opposition to it so strong, that they abandoned the project, and, having agreed to undertake the building of one of stone, obtained the necessary powers. For this purpose they

increased their capital from £100,000 to £500,000; and so sanguine were they of being still amply remunerated by the tolls, that the additional capital was all raised among themselves, and shares were at a guinea premium next day. The expense of the building, however, so much exceeded the estimate, that the company was under the necessity of raising about £500,000 more, by means of annuities on the tolls; and any chance of a dividend on the original shares has been thus postponed to so remote a period, that they have sunk in the market to a merely nominal price.

Waterloo, or *Strand Bridge*, as it was first called, consists of nine elliptical arches, each of 120 feet span, and thirty-five feet elevation. It is of the same width exactly as Blackfriars, and longer within the abutments than Westminster bridge by nineteen feet. The roadway is perfectly level, and in this respect the bridge has a decided advantage over every other on the river. The arches and piers are built of large blocks of granite, with short counter-arches over each pier. The adjustment of the equilibrium throughout the whole structure is said to be singularly perfect, the curve of equilibrium passing every where extremely near to the middle of the blocks. In building the arches, the stones were rammed together with great force, so that, on the removal of the centres, none of the arches sunk more than an inch and a half. In short, 'the accuracy of the whole execution seems to have vied with the beauty of the design, and with the skill of the arrangement, to render the bridge of *Waterloo* a monument, of which the metropolis of the British empire will have abundant reason to be proud for a long series of successive ages.'

The rapidity with which this great work was erected is not the least remarkable feature in its history. The foundation stone was laid on old Michaelmas-day in 1811, and on the 18th of June, 1816, the first anniversary of the battle of *Waterloo*, the glorious memory of which it is designed to commemorate, it was opened with great pomp by the prince regent in person, accompanied by his royal brother, the duke of York, the duke of Wellington, and a long train of persons of the first distinction.

Vauxhall Bridge, near *Vauxhall Gardens*, and hence called *Vauxhall Bridge*, was the first iron bridge over the Thames, and the project of Mr. Ralph Dodd, the father of the projector of *Waterloo Bridge*; but, alike in their fates, he also was deprived of the satisfaction of executing his design. On his dismissal, in consequence of some disagreement with the committee of persons who subscribed for its erection, the aid of Mr. Rennie was called in, and an act of parliament procured for the construction of a bridge according to a design which he proposed, and which was universally approved of at the time. Before operations commenced, however, a new plan was brought under the notice of the committee by Sir Samuel Bentham; and, after much discussion, and, it is said, not a little intrigue, it was resolved to adopt it in preference to the other. Mr. Rennie on this withdrew from any further concern in the undertaking, and the work was begun under the direction of Sir Samuel Ben-

tham. In a short time, however, the successful knight was dismissed in his turn, and it was left to Mr. J. Walker, an engineer of eminence, to complete the structure. The first stone was laid in 1813 by prince Charles, now duke of Brunswick. It is said to have cost £300,000. See **IRON BRIDGES.**

Southwark Bridge.—The great extension of buildings in the borough of Southwark, St. George's Fields, and other parts on the south of the river bearing immediately on London Bridge and Blackfriars, and consequent increase in the thoroughfare over these bridges, suggested the expediency of erecting an intermediate one from the bottom of Queen Street, Cheapside. The projectors of the undertaking were at the pains to obtain an accurate account of the persons, vehicles, and horses, that passed over these two bridges in the course of a day, and the following were the returns; the first taken on the 16th of October, and the second on the 22d of October, 1810.

LONDON BRIDGE.

Persons	56,180
Coaches and Chaises	871
Gigs and Taxed Carts	520
Waggons	587
Carts and Drays	2,576
Horses	472

BLACKFRIARS BRIDGE.

Persons	37,280
Coaches and Chaises	626
Gigs and Taxed Carts	526
Waggons	389
Carts and Drays	1,269
Horses	433

Calculating that one-sixth of these passengers would prefer the new bridge, the projectors saw in the toll that might fairly be imposed an ample return for the capital required for its erection. A toll of 1d. from that proportion of foot-passengers alone would produce upwards of £60,000, which would be more than sufficient to pay fifteen per cent. on a capital of £400,000, for which sum Mr. Rennie estimated that a bridge of cast-iron with stone piers might be executed, which, though of less costly materials, would rival in magnificence and splendor that of Waterloo itself.

An act of parliament was accordingly obtained, in 1811, for the erection of the proposed bridge; but a provision was inserted, that operations should not be commenced until £300,000 of the £400,000 admitted to be required were subscribed. The unexpected calls which had been made on the Waterloo Bridge Company had however so far damped the ardor for such speculations, that three years elapsed before the requisite sum was made up, and the work actually begun.

The Southwark Bridge consists of three immense arches of cast iron; the span of the centre one is 240 feet, and of the two side ones 210. The abutment is of fine masonry connected by dowels to prevent its sliding; and rests on gratings of timber supported by oblique piles. The piers stand on foundations nine or ten feet below the present bed of the river, and are abundantly

secured by a flooring of timber placed on piles. 'When we consider,' says M. Dupin, 'the extent and elevation of the arches of the bridge, and the magnitude of the elements that compose it, what an idea does it not give to us of the power of man! We exclaim involuntarily, while we gaze on the chef d'œuvre, 'Behold the Bridge of Giants!'

The subscribers are allowed by their act of incorporation to receive ten per cent. annually on their shares; and the remainder of the receipts is to be laid by and to accumulate until it shall become sufficient to pay each proprietor double the sum he subscribed, after which the bridge is to be made free to the public.

The Tower.—Antiquaries are very eager to give the tower of London a Roman origin; and from the circumstance of an ingot of silver having been discovered, in digging the foundations for a new ordnance-office, have inferred, that it was not only the capital fortress of the Romans, but their treasury and their mint. One historian, more minute than the rest, even considers this identical ingot as a portion of the last treasure sent into Britain for the payment of the Roman forces! That the Romans might have fortified the banks of the Thames, on this spot, is by no means improbable; but there is not the slightest evidence that they ever did so; nor is there any proof of a building having been erected here, until the time of William the Conqueror, who built the White Tower. In an age when ecclesiastics were the principal architects, and bishops exchanged their crozier for a baton, and marched at the head of armies, it was not surprising that those who possessed the talents should employ them in military architecture. Hence the tower was actually built by Gundulph, bishop of Rochester; but so obscure is every thing connected with the early history of this fortress, that even the date of its erection is unknown, though it must have been begun about the year 1080.

Whether any thing more than the White Tower was built in the reign of William seems doubtful; but his successors, William Rufus and Henry I., are known to have made considerable additions to the original structure, and the former surrounded the tower with a wall in the year 1096.

Though the first object of the tower might be as a fortress, yet its history is much more interesting as a palace and as a state prison. As a fortress, it has never had to defend itself against a foreign enemy, though in the domestic troubles, which at an early period of our history agitated the metropolis, the tower was always considered of importance, and its garrison sometimes called into action; and Mandeville, in whose family the custody of the tower was at first made hereditary, defended it successively against the Londoners in the time of Stephen, and even made a sortie from it as far as Fulham, carrying off the bishop of London from his palace.

Longchamps, bishop of Ely, who was made keeper of the tower during the absence of Richard I. in the Holy Land, found it a place of refuge when his tyranny had roused the no-

bles to resistance. He increased its fortifications, and surrounded them with a deep ditch; and, had he not been as cowardly as he was tyrannical, might have maintained a long resistance; he however surrendered the fortress, and sought personal safety in flight, disguised as a female. Prince John, who had assisted the barons in overthrowing the despotism of Longchamps, assuming the tyrant himself, had no sooner gained the throne than he had to defend the tower against them. At the commencement of hostilities, the barons, to whom the citizens had given the charge of the capital, laid siege to the tower, which, though feebly garrisoned, defended itself until the promise of a charter of liberties was wrested from the reluctant monarch. The archbishop of Canterbury was appointed to hold the tower, in trust, until the king fulfilled his promise, and signed Magna Charta. In his subsequent attempts to violate the compact he had signed, he was not able to gain possession of this fortress, which was kept by the archbishop until the arrival of prince Louis of France, who had been invited to the English throne, and to whom the tower was given up. While John lived, and England was torn by intestine wars, the French prince entertained hopes of the crown; but, on the death of that weak and perfidious monarch, loyalty to the native princes returned, and Louis was compelled to give up the tower to Henry III. who augmented its fortifications with an additional line, and built the great hall, the royal chapel, a state chamber, &c. This monarch was anxious to make it suitable as a royal residence, by the splendor and convenience of its apartments; he was equally careful to render it secure, as a place of retreat from the growing turbulence of the barons. Some works of considerable magnitude had been raised, and were barely completed, when, on St. George's day, in the year 1240, the foundations gave way, and the walls and bulwarks, with a grand portal, fell down; they were immediately rebuilt; when, if we are to believe Matthew Paris, on the following year, and on the same day and hour, the whole again fell down.

All design of enlarging or strengthening the tower was now suspended for some time; and indeed the king was unable to keep possession of it; for in 1258 the parliament of Oxford wrested the sceptre from his feeble hands, and established a government of twenty-four barons, and seized upon the tower. The measure was, however, too violent, and the king resumed his authority; but the tower was now rather a fortress, where he could defend himself, than a palace; and he at length yielded to the commands of the refractory barons, by subscribing conditions more humiliating than even the parliament of Oxford had demanded. He yielded up all the castles and fortresses, and consented that all foreigners who were obnoxious to the twenty-four barons, who were thus reinstated in power, should be banished. The queen, who possessed more spirit than her husband, indignant at a treaty which banished aliens, quitted the tower before the barons entered, and endeavoured to reach Windsor, where her son, prince Edward,

had a strong garrison of foreign troops. She left the tower in a barge; but had scarcely reached London Bridge, when a mob collected, and not only assailed her with the most indecent language, and cries of 'drown the witch,' but they actually pelted her with every thing they could lay hold of, which compelled her to return to the tower.

On the restoration of Henry to his authority, Otho, the pope's legate, fixed his residence in the tower, and had soon to sustain a very vigorous attack made by the earl of Gloucester, whose new insurrection again endangered the king's crown. Otho, assisted by the Jews, who had taken refuge in the tower, maintained the fortress until relieved by the king, who had marched from Cambridge, and, being joined by his son from the north, invested the city with 60,000 men. He threw succours into the tower, and carried off the legate; but it was not until a large fleet of Gascoigns sailed up the Thames, and lay before the tower, that the rebels sued for peace, which was granted.

Edward I. completed the fortifications commenced by his father, erected some additional outworks to the west, and enlarged the moat considerably. His son and successor, Edward II., fearing attacks from the barons, who had become provoked by his favoring the oppressions of Piers Gaveston and the De Spencers, endeavoured to make the tower impregnable by additional fortifications, and by reinforcing the garrison. He did not, however, venture to defend it against the conspiracy of Mortimer and queen Isabella; but on their approach to the capital, having failed in rousing the Londoners to resistance, he left the tower in charge of the bishop of Exeter. The citizens only waited for the king's departure, to display that rebellious spirit which was too manifest; they took the tower by surprise, seized the amiable prelate, and several other persons attached to the king, and cut off their heads. The king was soon afterwards made prisoner, and the two De Spencers hung. The queen entered the city in triumph, accompanied by prince Edward, and a parliament was called, which transferred the crown from Edward II. to his son.

During the victorious reign of Edward III. the tower is only interesting on account of its illustrious prisoners, the kings of France and Scotland, who for some time were its inmates.

When the fatal insurrection of Gloucester threatened the power of Richard II., and the tower was blockaded, he invited the leaders to a conference within its walls. They refused, fearing they might be surprised; until the weak monarch, in order to remove all suspicions, sent them the keys of the gates and the strong turrets, and offered to admit 200 armed men. The proposal was too favorable to be refused, and the rebels agreed to the conference. The king received them in a splendid pavilion, and agreed to go to Westminster, where he was compelled to submit to the execution of many of his most faithful followers: he soon saw the result of his weakness, and although he returned to the fortress it was only as a prisoner, to abdicate the throne to his rival.

Jack Cade, whose insurrection has already been noticed, on entering London, attempted to besiege the tower; but it was, at that time, defended by a strong garrison, and commanded by a brave governor, lord Scales, who was very active in putting down the insurrection.

During the wars between the houses of York and Lancaster the tower was vigorously besieged by the Yorkists. Sir John Wenlock carried on the siege on the eastern side of the fortress; artillery was planted to the south, on the opposite side of the river; and lord Cobham, with some city aldermen, conducted the siege on the west. Lord Scales, unable to defend the place against such a force, left the tower by water, but he was seized and killed, and his naked body thrown on the bank of the river.

From this time the tower ceases to be interesting as a fortress; for, during the civil wars, it was successively occupied by the different parties, without a sword being drawn or a shot being fired; and, when James II. quitted the capital, it was secured immediately for the prince of Orange. In times of alarm, measures have been taken for strengthening the city fortress, as was the case so late as 1792, when the garrison was increased; 'several hundred men,' says Bayley, in his *History of the Tower*, 'were employed in repairing the fortifications, opening embrasures, and mounting cannon; and, on the western side of the fortress, a strong barrier was formed with old casks, filled with earth and rubble: the gates were closed at an early hour, and no one but the military allowed to go upon the ramparts.' But from the time that the tower was first erected, until the reign of queen Elizabeth, it was frequently used as a palace where our monarchs 'kept open household and frank resort,' and where the royal court, and even parliaments, were held. From the tower all processions and pageants generally proceeded, whether it was to a tournament or a coronation: and the kings of England, from the reign of Richard II. to the accession of James II., always proceeded from the tower to Westminster to be crowned, in grand procession, with the exception of Charles I. who was prevented by the plague.

Gorgeous as the procession of queen Elizabeth appears to have been, it was surpassed at the coronation of Charles II.; at least so Heath would have us believe, for he assures us, in his *Chronicle*, that 'all the world that saw it, could not but confess, that what they had seen before, was but solemn mummery to the most august, noble, and true glories of this great day: even the vaunting French confessed their pomps of the late marriage with the infanta of Spain, at their majesty's entrance into Paris, to be inferior in state, gallantry, and riches, to this most glorious cavalcade from the tower.'

The fortifications of the tower occupy a space of about twelve acres, and consist of a citadel, or keep, encompassed by an inner and outer ward, and surrounded by a moat supplied with water from the Thames. There are four entrances: the principal one is over a stone bridge at the south-west angle of the enclosure, where there was formerly a large draw-bridge.

In addition to the two draw-bridges on the south side, which separate the fortress from the quay, or terrace, on the banks of the Thames, there is also a private entrance by water, under a strong tower, which is called the Traitor's Gate, on account of its being the way by which state prisoners were brought to the tower. The barbican, which formerly stood beyond the ditch on the west, no longer exists. The entrance to the principal bridge is protected by a strong tower flanked with bastions; and the fortress is so constructed as to afford many precautions against sudden surprise, or a full capture of the place, even if the outer works should be occupied. The principal royal apartments were in the inner ward, which was formerly enclosed by a lofty wall of stone, about forty feet high, and from nine to twelve feet thick. It was also embattled and strengthened with thirteen small towers, most of which, as well as a considerable part of the wall, still remain.

The White Tower, though the largest, the most ancient, and the most complete, is by no means the most interesting part of this fortress. It is a massive edifice of a quadrangular form, 116 feet long, ninety-six broad, and ninety-two feet high; it is embattled, and has a turret at each angle; one of these turrets was used by Flamstead as an observatory, previous to the establishment of the royal observatory at Greenwich. On the first floor of the White Tower are two large rooms, one of which is at present used as a repository for cavalry arms, and the other as a tool house. There are also a vaulted room and a cell evidently intended for prisons: and tradition relates, that in one of these cells Sir Walter Raleigh wrote his *History of the World*. Here, too, were confined several of the persons connected with Sir Thomas Wyatt's rebellion in 1553-4, two of whom have left the following inscription on the sides of the doorway leading to the cell. 'HE THAT INDVRETH TO THE ENDE SHALL BE SAVED. M. 10. R. RYDSTON DAR. KENT. ANO. 1553.'—'BE FAITHFVL VNTO THE DETH AND I WILL GIVE THE A CROWNE OF LIFE. T. FANE, 1554,' and underneath the inscription is 'T. Cylpepper of Darford.'

On the second floor are two rooms used as armories, and an apartment commonly called Cæsar's chapel, which Mr. Bayley, to whose *History of the Tower* we acknowledge ourselves indebted, says, 'may justly be said to exhibit one of the finest and most perfect specimens of the Norman style of architecture now extant in this country.' When the sovereign held his court in the tower, this chapel was used for the private devotions of the royal family and household. A chaplain regularly performed service here, whose salary, in the reign of Henry III., who greatly ornamented the chapel, was fifty shillings a year. The chapel, which was dedicated to St. John the Evangelist, has long ceased to be a sacred room, and is now appropriated as one of the rooms of the record office. The uppermost story of the White Tower exhibits a massive timber roof of great antiquity. The principal room on this floor is traditionally reported to have been the council chamber; and

here the duke of Gloucester, afterwards Richard III., is said to have ordered the execution of lord Hastings, and the arrest of the archbishop of York, the bishop of Ely, and lord Stanley.

In addition to the chapel already noticed, there is another in the fortress which was erected in the reign of Edward I., and was dedicated to St. Peter ad Vincula. It is a plain building quite destitute of ornament, and derives its sole interest from its being the cemetery where so many noble and distinguished personages at last found repose, after falling the victims of the tyranny or jealousy of Henry VIII., whose soul must have been appalled at the recollection of the chapel of St. Peter, could the consciousness of guilt appal it.

Here rest the remains of the lovely Anne Boleyn, whose absence the monarch once declared, 'gave greater pains to his heart, than angel or scripture could express;' and yet he sent her, and her innocent brother, (George Boleyn, lord Rochford (who is also buried here), to the block. If the spirits of the dead could be disturbed by the vicinage of crime, those of the queen and her brother might be so, for here the wife of the latter, the wretched agent of the king in their death, is buried. She was an accomplice in the crimes of queen Catharine Howard, another of Henry's wives, and with her was executed and buried. The pious prelate, John Fisher, bishop of Rochester, who was reduced to the melancholy situation of begging food, a shirt, and other clothes, and who, when found to survive this treatment, was beheaded, sleeps in the same tomb as his patron, Thomas Cromwell, earl of Essex, so long the favorite of the king; and with them rests, in eternal peace, the virtuous Sir Thomas More, lord chancellor. All these were sacrificed to the tyranny, jealousy, or caprice of Henry VIII. The last of the Plantagenets, Margaret, countess of Salisbury; Edward Seymour, duke of Somerset, lord protector, who was executed in 1552; and his brother, the haughty Thomas Seymour, baron Sudley, whom he had three years before sent to the block, sleep in peaceful amity, with the ambitious John Dudley, duke of Northumberland, the enemy of their house, who raised himself on the ruin of Somerset, and, like him, fell a victim to his ambition.

Here also reposes the victim of paternal and fraternal affection, Gerald Fitzgerald, ninth earl of Kildare, lord deputy of Ireland, who died of a broken heart, a short time before his son, and five of his brothers, who were executed for participating in the treason with which he was charged.

Here also are entombed two of the victims of queen Elizabeth's jealousy, Thomas Howard, duke of Norfolk, executed for aspiring to a union with Mary queen of Scots, and the once favorite Essex. The ill-fated James, duke of Monmouth, is also buried here, as are the three Scottish peers who joined in the rebellion of 1745; the lords Kilmarnock, Balmerino, and Lovat, who are all buried in the same grave. The leaden plates which had been fixed on their coffins are still preserved in the chapels, and bear similar inscriptions, with the alteration

of the name and age of the parties. That on lord Lovat is

Simon Dominus
Frazer de Lovat
Decollat. Apr. 9, 1747
Ætat. suæ, 80.

Several officers of the Tower are also interred in this chapel, and, among others, that faithful guardian of the regalia Talbot Edwards, who defeated colonel Blood's attempt to steal the crown. The advowson of this chapelry is in the crown, and the annual stipend £115 5s.

In the lieutenant's house, a large and inconvenient old building, usually occupied by the major, or resident governor, there is a monument recording the gunpowder plot conspiracy.

The Bell Tower is of a circular form, with a curious vaulted roof. It was in this tower that Fisher, bishop of Rochester, was confined; and tradition, without any good ground, also marks it as the place of queen Elizabeth's confinement. It is now used as one of the domestic offices of the governor.

Connected with the Bell Tower, by a paved foot-way, is the Beauchamp, or Cobham Tower, which has always been one of the principal state prisons. It takes its double name from Thomas de Beauchamp, earl of Warwick, a prisoner here in 1397, and from the Cobhams, who were also its inmates for Wyatt's conspiracy. The Beauchamp Tower consists of two stories, whose walls bear numerous records of the misery of those who were confined within them, and, destitute of books or paper, beguiled the time in inscribing memorials of their sufferings on their walls.

Among the distinguished prisoners in this tower was Philip, earl of Arundel, son of the duke of Norfolk, whose execution has already been noticed. The earl, who had been arrested on frivolous charges, and condemned on very questionable evidence, was reprieved by Elizabeth, and, after lingering ten years in confinement, died on the 19th of October, 1595, in the fortieth year of his age. His principal crime was that of being a staunch papist; and it is said that the descendants of the family consider him so much a martyr to the Roman Catholic religion, that a late duchess procured the skull, and had it enched in gold, as a valuable relic. This earl has left several inscriptions on the walls of this tower, expressive of his innocence.

John Dudley, earl of Warwick, who died in this tower in 1553, has left a piece of well executed sculpture near the fire-place, representing the bear and ragged staff (the family arms), surrounded with a border of oak sprigs, roses, and other flowers.

Another prisoner, Charles Bailly, an adherent of Mary queen of Scots, who once suffered the tortures of the rack without making any disclosure of importance, has left some moral reflections neatly inscribed on the walls of his prison. Here Dr. Story, who was executed at Tyburn in 1571, has also inscribed his name on the walls. A singular circumstance attended his execution: he was cut down before his senses had left him; and is reported to have

struggled with the executioner, while the latter was carrying into effect that revolting part of the punishment of traitors (now repealed) tearing out his bowels. One of the charges against Dr. Story was, for consulting with a noted magician against the queen's life, and for having cursed her daily in his grace at meals!

Pious ejaculations, moral reflections, worldly advice, and records of personal suffering, form the subjects of nearly all the inscriptions; and only one individual has left a memorial of his attachment to the sex; it is that of a prisoner whose name is only known from the circumstance, and of whose crime there is no record. A bleeding heart, with the initials, T. W. and P. A., are subscribed with the following words: 'Thomas Wyllingar goldsmith—My hart is yours till dethe.'

The Beauchamp Tower is traditionally said to have been the prison of Anne Boleyn and Lady Jane Grey; but, though there is no evidence to support it, it is by no means improbable, as it was long more used as a prison than any of the towers. Some of the state prisoners of 1794 were confined here.

The Jewel Tower, where the regalia are now kept, was formerly known by the name of the Martin Tower.

The Broad Arrow Tower is of smaller dimensions than the Beauchamp Tower, but, like it, has been much used as a prison, and its walls contain numerous inscriptions, few of which are of interest; indeed, our prison albums are much less interesting than those discovered in the Bastille, on its demolition in 1789.

The Salt Tower contains a very singular and hieroglyphical device by one 'Hew Draper, a tavern keeper at Bristol,' who was committed here on the 21st of March, 1560, on the accusation of 'one John Man, an astronomer, as a suspect of a conjurer or sorcerer, and thereby to practice matter against Sir William Lowe and my ladie;' a lamentable instance of the facility, with which life and liberty could, in those days, be sacrificed.

The Lanthorn Tower was of considerable antiquity, and formerly contained the king's bed chamber. It communicated with the great hall, the scene of many a royal banquet in the reigns of our Henries and our Edwards. The Lanthorn Tower was considerably damaged by fire in 1788, and soon after its remains were taken down. The site of this tower, and of several other parts of the ancient palace, are now occupied by the buildings of the Ordnance office.

The Bloody Tower is thought to have derived its appellation from the circumstances of the two princes, Edward V., and his brother, Richard, duke of York, who are supposed to have been put to death here, by order of their uncle, the duke of Gloucester. Mr. Bayley, who doubts whether the royal brothers were murdered in the tower, and ridicules the idea of calling it bloody when the children were smothered, infers, that if they were put to death in this fortress at all, it must have been at a different part of it; as the bones discovered in the time of Charles II., which, on account of their appearing to be those of children, had afterwards royal interment in

Henry VII.'s chapel, were found on the south side of the White Tower, which is at a considerable distance from the place where the deed is supposed to have been perpetrated. In addition to the towers thus described, there were several others, of some of which nothing but the foundation remains; nor is the history of them interesting even in their ancient state.

The history of the tower of London forms a black page in the early annals of this country, as, on account of the security it presented, the most illustrious prisoners have always been confined within its walls.

A lamentable catastrophe attended one of the first prisoners of royal blood that tenanted it. This was Gryffydd, the eldest son of Llewelyn, prince of Wales, who attempted to make his escape from this prison in 1244. He had formed a rope of the hangings, sheets, and table cloths, with which he let himself down from the top of the Tower; but, being a very corpulent man, the rope broke, and he was dashed to pieces. In the reign of Edward III., two sovereigns, taken prisoners in two distant wars, were confined in the tower—John, king of France, and David, king of Scotland; both were treated with the highest respect, and even with delicate attention, by Edward, and his gallant son, the Black Prince.

It was in the tower that lady Arabella Stuart died the victim of grief. This amiable princess was an object of unjust suspicion with both Elizabeth and James, though guilty of no other crime than that of marrying a man she loved, William Seymour, grandson of the earl of Hertford. For this offence, she was committed to the tower, while her husband was also committed to prison. Both the prisoners contrived to escape, and intended to pass over to France, but were seized and brought back to prison. The lady Arabella was more strictly watched than ever; and it appears by her autograph letters, of which there are several in the possession of lord Weymouth, as well as in the British Museum, that she was even deprived of necessary comforts. In a letter to viscount Fenton, she entreats his lordship to make known to the king her 'most discomfortable and distressed state;' and in another part of the letter, which she had afterwards cancelled, she complains that she cannot get any thing but ordinary diet, and that unfit for a person suffering under sickness, as she was. It was in vain that she presented memorials to the king, and sought the good offices of the queen, and such of the nobility as she thought had influence with his majesty—for the relentless James left her to perish in the tower. In the Harleian MSS., vol. 7003, there is a fragment of one of her letters to the king, which forcibly exhibits her humility, and the unfeeling character of James.

During the civil wars of Charles I., the protectorate, and after the restoration of Charles II., the tower was not wanting in inmates.

In a collection of pamphlets, which were presented by his late majesty to the British Museum, there is a folio sheet, printed in September, 1647, which gives us a list of the prisoners in the tower at that time. It is entitled 'A Loyall Song

of the Royall Feast, Kept by the Prisoners in the Towre, in August last, with the names, titles, and character of every prisoner. By Sir F. W., Knight and Baronet, prisoner.'

The song, which contains twenty-five stanzas, is curious, as showing the staunch loyalty of the prisoners, and the humor of one of them at least, even in his confinement. It thus commences :—

'God save the best of kings, King Charles,
The best of queens, Queen Mary,
The ladies all, Gloster and Yorke,
Prince Charles so like old Harry:

God send the king his own again,
His Towre and all his coyners,
And bless all kings who are to reigne
From traytors and purloyners.

The king sent us poor traytors here
(But you may guesse the reason,)
Two brace of bucks to mend the cheere;
Is't not to eat them treason !'

The writer of the song, which is an imitation of the ballad of Chevy Chase, enumerates the names of the prisoners, all of whom he eulogizes for their good conduct.

The tower still continues to be used as a state prison ; here the last victims of attachment to the exiled house of Stuart perished ; and here, in 1794, Mr. Horne Tooke, Hardy, and the other persons charged with high treason, were confined : one of them, John Augustus Bonney, has inscribed, on the walls of his prison, an epitaph on a cat, which, with true republican feeling, he called *citizen*, and the following epitaph on a goldfinch.

Where Raleigh pined, wit' in a prison's gloom,
I cheerful sung, nor murmured at my doom ;
Where heroes bold, and patriots firm could dwell,
A goldfinch in content his note might swell ;
But death, more gentle than the laws decree,
Hath paid my ransom from captivity.

Buried, June 23, 1794, by a fellow-prisoner, in the Tower of London.

The last time that the tower of London was used as a state prison, and may it long continue the last, was in the year 1820, when Thistlewood, and his associates in the plot, known by the name of the Cato Street Conspiracy, for massacring the whole of the king's ministers, were confined here. During their trial they were brought every morning from the tower to the Old Bailey, and conveyed back again in the evening. When five of them had been found guilty, and sentenced to death, they were executed in front of Newgate, and not on Tower Hill, as was formerly the custom.

Within the walls of the tower are the Mint, the Jewel Office, the Armoury, the Ordnance Office, the Record Office, and the Menagerie.

The Ordnance Office, of which his grace the duke of Wellington is at present master, superintends the supplying of arms, ammunition, and other warlike stores required in the service. When the principal arms consisted in the bow, the officers of this establishment were called the bowyer, the cross-bowyer, the armourer, &c. In time of war, the number of officers, clerks, and

wardens, in the Ordnance Office, exceeds 300 exclusive of porters, servants, and other attendants.

The Record Office contains the parliamentary rolls, from the reign of king John to that of Richard III. : a survey of the manors of England and a register of the ancient tenures of all the lands ; ancient perambulation of forests ; a collection of charters granted to colleges and corporations ; the book of prayer under the great seal, printed and sanctioned by Charles II., on his restoration, together with several state papers, and documents of great antiquity.

The public records of Scotland, which Oliver Cromwell seized on, were placed in the tower, where they remained until the restoration, when Charles II., intending to return them to Edinburgh Castle, sent them in a vessel, which was wrecked near Holy Island, and the valuable documents were lost.

The Royal Menagerie in the tower, where our monarchs formerly amused themselves with seeing the combats of wild beasts, is not remarkable either for the number or the rarity of the animals it contains ; and, as a collection of natural history, is unworthy of a great nation, whose fleets and armies would enable them to collect all that is wonderful in nature or art from every clime.

The government of the tower is vested in a constable, a lieutenant, and other subordinate officers. The opening and shutting of the gates, in the morning and evening, is done with great ceremony, and is almost the only circumstance that reminds the inhabitants of London that they have a fortress within their walls regulated by a military government. The warders, who attend at the tower, and wear the livery of the yeomen of the guard, were appointed to their office by Henry VIII. The king, after residing in the tower some months on the death of his father, left fifteen of his body guard, and gave them the name of warders ; and afterwards, in consequence of their attention to the protector, duke of Somerset, when confined there, he procured them the honor of wearing the same livery as the yeomen of the guard.

The Jewel Office.—It is probable that, from the moment the tower became a royal residence, it was the place where the regalia were deposited, though the first evidence on record, of its being used as a jewel office, is an order made in the fourteenth year of Henry III., to the bishop of Carlisle, directing that the four coffers of the king's jewels should be 'laid up in the tower.' From this time the regalia appear to have been kept in the White Tower until about the middle of the seventeenth century, when they were removed to a stone room near the grand store house, which has since been known by the name of the Jewel Office.

The situation of keeper of the regalia was formerly considered an office of great honor and dignity, as well as trust. In the reign of Edward III. John Flete, the first keeper of the jewels, whose name has been preserved, had an allowance of twelve pence per day, which was, in succeeding reigns, gradually increased, so that, in the time of Henry VIII., it was £50 per

annum. The smallness of this salary might induce an opinion that the office was not of much importance, did we not find it held by persons of consideration, among whom was Thomas Cromwell, the favorite and victim of Henry VIII. This officer was formerly styled Master and Treasurer of the Jewel House; and, in addition to the care of the crown jewels in the tower, he had the purchasing and custody of the royal plate—the appointment of the king's goldsmiths and jewellers—the supplying of plate to ambassadors, &c. His emoluments amounted to £1300 a year in the reign of Charles II., although they had then undergone considerable reduction. It was during the time that Mr. Edwards held this office, that colonel Blood made the daring attempt to carry off the crown of England, in which he so nearly succeeded. See BLOOD.

The value of the regalia in the jewel-office in the tower is estimated at £2,000,000 sterling. The most prominent and the most costly article is the new imperial crown, first used on the coronation of his present majesty in 1821. This splendid crown, which is unrivalled in value and elegance, is enclosed in a glass globe, which is made to revolve by some ingenious machinery, invented by Mr. March, the resident officer of the board of works in the tower. By this means, the spectators see every part of it, while six powerful argand lamps are so disposed as to throw upon the jewels every hue their prisms can exhibit.

In the jewel office there are four other crowns, and seven sceptres. One of the sceptres, with a dove on it, was discovered in 1814 behind a part of the old wainscotting of the jewel-house, where it must have remained several years. It is thought to have been the sceptre made for queen Mary, who was not only the queen consort of William III., but also queen regnant conjointly with her husband. Here, also, are the golden orb, which the King holds in his right hand at his coronation; the swords of mercy and of justice; the large golden salt cellar, which forms a model of the white tower; a grand silver font, used at the baptism of the royal family, and the banqueting plate used at the coronation feast; the ampulla, or golden eagle, for the consecrated oil with which the king is anointed, and all the other regalia used at the splendid ceremonial of a coronation. See CORONATION.

The armoury.—Until the last age of chivalric splendor, the sixteenth century, we read of no armouries in Europe. Then Henry VIII., Francis I., Charles V., and Maximilian I., laid the foundations of four of the best in Europe: yet their collections were all modern; and Dr. Meyrick, in his valuable work on the origin of armour, has very satisfactorily proved, 'that although in private families a few suits of earlier date had been preserved in Italy, that of Maximilian, with its steel lamboys, and that of Henry VII., resembling it, are the oldest specimens in Germany and England.' Such a declaration is greatly at variance with all preceding descriptions of the armour in the tower, and most of the pretensions of such collections: hence the Ambras collection, now at Vienna, though containing armour of the same period as the suits in the

tower, has equally with it been asserted to possess specimens of great antiquity, exhibiting the suits pretended to have been worn by the German emperors from the time of Albert I., emperor of the Romans, down to the period when body armour was principally relinquished.

It appears from a survey made by order of Charles II. in October, 1660, that the principal armour now in the tower was then at Greenwich, whence it has subsequently been removed. During the civil distractions of the preceding reign, the armoury in the green gallery, at Greenwich, was despoiled by the soldiers, and what remained was afterwards transferred to the tower. In this survey, which is signed by Sir John Robinson, lieutenant of the tower, and other officers, appointed to make the investigation, there is not the slightest mention of the Spanish armoury, or the thumb-screws, racks, and wire-whips, which now form so attractive a feature in this exhibition; and yet the surveyors give a very minute list of every thing found in the armouries of the tower and Greenwich. The Spanish armoury must, therefore, have been made up subsequent to the reign of Charles II., and its genuineness consequently becomes more than doubtful. In Burghley's State Papers, a lottery of foreign armour, probably that of the Armada, is said to have been drawn in the twenty-ninth year of Elizabeth, and if the instruments of torture, and the Catholic banner, now exhibited, are really spoils of the Armada, they must have been collected at least a century after they were dispersed by the lottery. There is, however, so little reason to believe, that any portion of the armour, called Spanish, is really so, that little faith can be placed in the authenticity of the instruments of torture which the growing enmity to the Roman Catholics would readily ascribe to them. The targets with pistols in them, exhibited as Spanish, were in the tower in the reign of Edward VI., and therefore could not have belonged to the Armada; the pikes, shown as Spanish, were common to the English soldiery; as well as the Spaniards; and the glaives, bills, halberds, &c., which principally form this collection, were used in England in the reign of Henry VIII. But then there is queen Elizabeth, in the very armour, we are told, which she wore when she rode on a steed, richly caparisoned, to review her forces at Tilbury Fort. Unfortunately, however, for the correctness of this statement there is not the slightest evidence of her majesty having worn armour on this memorable occasion; and it farther appears, that the fluted breast-plate, and the *garde-de-reine*, in which her figure is now enshrined, belonged to her father, and that they could not have been worn in a sitting posture; and the armour for her arms is of the time of Charles I. Nor are the other parts of the equestrian exhibition of armour in the tower more correct: the armour attributed to William the Conqueror is of Edward VI.'s time, or of the early part of Elizabeth's reign; the suit worn by Edward I. in the tower is also of the reign of the sixth Edward, with the addition of a *marte de fer*, of the time of James I., placed in his hand. Edward III. wears a suit of white armour of Henry VIII.'s time, and Henry IV. is

encased in another suit of the time of Edward VI. The armour of Henry V., which we are assured *he wore at the battle of Agincourt, is composed of various pieces, some of which were not made until two centuries after this memorable victory*: the upper part of the armour is of the time of Charles I., while the legs, which, like those of old Jacob Tonson, are not fellows, are of the reign of Henry VII. Henry VI. and Edward IV. have also each borrowed a pair of legs from Henry VIII., and a suit of body armour from Charles I.: while Edward V. wears a rich and highly decorated suit, which appears to have been made for that promising youth, Henry, prince of Wales, son of James I. Henry VII., no doubt, wears his own armour, and it is one of the greatest curiosities in the tower, for the lamboys, or puckerd petticoat, is so contrived, as to reach the saddle behind, and then fall on each side. Henry VIII. wears what may be fairly considered his own proper armour,—the legs perhaps excepted. Edward VI. wears a suit, which seems to have been made for prince Henry, son of James I., but, in compliment to the piety of the young king, a variety of scriptural subjects are engraved on it in different compartments. James I., who would not easily have been induced to trust himself in a suit of armour, is encased in one which belonged to the earl of Warwick, about the time of Elizabeth or Mary. King Charles I. wears a rich suit of gilt armour, which was presented to him by the city of London when prince of Wales. His son and successor, Charles II., wears a splendid suit, of the time of Edward VI.; as does William III., while George I. and George II. wear the armour of the time of Henry VIII.; the former having the addition of a Turkish bridle.

Thus, of the seventeen monarchs who appear in armour in the tower, only three wear that of the period in which they lived: and in the small armoury, the figures which represent king John, Henry III., Henry V., and Henry VI., are all in suits of cavaliers' armour, of the time of Charles I., with flaming swords which are of a still later date.

De Courcy, the ancestor of the earls of Kinsale, of whose strength and prowess so many anecdotes are related, wears the armour of a demi-lancer of the time of Edward VI., with a helmet of Henry VII.; John of Gaunt, 'time honoured Lancaster,' wears a gigantic suit of armour, seven feet high, of the time of Henry VIII.; Charles Brandon, duke of Suffolk, and the jester, Will. Somers, wear suits of the time of Charles I. or II.

But although the armour in the tower is thus inappropriately displayed, it is sufficiently rich and varied to admit of a correct arrangement of several perfect suits, and it is much to be wished, that such a classification of it were made.

The tower armoury is highly curious and interesting, not only for these relics of antiquity, but for the ingenious and tasteful manner in which 100,000 stand of modern arms are displayed. The royal train of artillery, capable of dealing destruction on all around, is also an object of wonder and awe; but the curious will probably be more gratified in viewing the state

swords of the Pretender, the shield of the earl of Mar, or the axes with which Anne Boleyn, and the earl of Essex, Elizabeth's favorite, were beheaded: but for the authority of which we will not vouch, since, with respect to Ann Boleyn, Stowe assures us, that her head was severed from her body at one blow with a sword.

Tower Hill.—At what period Tower Hill was first fixed upon as a place for public executions is by no means certain; but it does not appear to have been used as such until long after the fortress had become a state prison; for we find that, in the year 1196, William Fitz Osbert, who had been tried and condemned in the tower, for 'seditiously moving the common people to seek liberty,' was drawn by the heels to the elms at Smithfield, and there hanged. A similar instance occurred in the year 1330, when Roger Mortimer, earl of March, who had been imprisoned in the tower, 'condemned by his peers, and yet never brought before them,' was hanged on the common gallows at Smithfield.

One of the earliest executions on Tower Hill appears to have been that of the accomplished Sir Simon de Burley, the tutor of Richard II., who was sent to the block in the year 1388. From this time the quadrangle and green-yard within the Tower Hill were the places where state-prisoners generally suffered.

In 1495 Sir William Stanley, chamberlain to Henry VII., whom he had faithfully served, was here beheaded for no other crime than that of having said, that 'if he certainly knew Perkin Warbeck was the undoubted son and heir of king Edward IV. he would never fight or bear arms against him.'

Henry VIII. had not long been seated on the throne before the axe on Tower Hill was employed; nor did he suffer it to rust. Had he, however, been guilty of no worse act than that of sending Empson and Dudley to the scaffold, his name and memory had not been stained with guiltless blood. They were beheaded on the 18th of August, 1510, for arbitrary exactions and embezzlement of money; and several of their agents were set in the pillory here with labels on their heads relating their crime.

In the same reign were executed here the duke of Buckingham, sacrificed by cardinal Wolsey; Fisher, bishop of Rochester, for denying the king's supremacy; Sir Thomas More; lord Rochford, the brother of Ann Boleyn, who two days before had suffered within the tower, and four alleged accomplices of the queen's guilt. Several illustrious victims followed in the persons of the marquis of Exeter, the earl of Devonshire, lord Montacute, and Sir Edward Nevil.

Lord Leonard Grey, deputy of Ireland, was executed for having connived at the escape of his nephew, lord Dazey; Thomas lord Cromwell, Thomas Seymour lord high admiral, the protector duke of Somerset, the duke of Suffolk, father of lady Jane Grey, Sir Thomas Wyatt, and Thomas duke of Norfolk, successively perished beneath the axe on Tower Hill.

During the reign of James I. the only execution on Tower Hill was that of Sir Gervas Elwas, lieutenant of the tower, and one of the accomplices in the horrible murder of Sir Thomas

Overbury within its walls. Sir Walter Raleigh did not suffer near the prison, where he had been confined for nearly fourteen years, but was executed in Old Palace-yard. The infamous earl of Castlehaven here met a just punishment; and here perished the earl of Stafford, Sir Alexander Carew, Sir John Hobbam and his son, archbishop Laud, Mr. Love the minister, and captain Brown Bushel, who fell victims of the civil and religious feuds of the times.

Of the regicide judges, on whom Charles II. revenged his father's death, Sir Henry Vane was the only one executed on Tower Hill; but the accomplished earl of Strafford, and the patriotic Algernon Sidney, here paid their debt before nature had demanded it.

The ill-fated duke of Monmouth, when led to the scaffold on Tower Hill, was attended by a very strong guard, on account of his known popularity. The executioner seemed to feel dismayed at his office; for, after giving three blows with his axe, on the neck of the unfortunate duke, who bore them all without moving any thing but his eyes, as if reproaching him, he threw down the fatal weapon, nor did he resume it until the sheriff by threats urged him to go on, and twice again, was his strength exerted ere the head was severed from the body.

The next individual who suffered on Tower Hill was Sir John Fenwick, in 1696, who was detected in a plot to assassinate king William.

Although some of the old maps of London represent a gallows on Tower Hill, and more than one historian relates, that there was one erected there, yet there are considerable doubts of the fact; for we invariably find that even prisoners in the tower, when condemned to be hanged, were either taken to Smithfield or Tyburn; nor was there ever a permanent scaffold here.

The rebellion of 1715 gave a few of the faithful adherents of the house of Stuart to the block: although, considering the extent of the treason, and the daring character of the individuals who were principals in it, no subdued insurrection was ever followed with greater clemency. Two Scottish Peers, who, among several others, had been taken, suffered on Tower Hill, the earl of Derwentwater and lord Kenmure. The earl of Nithsdale, ordered for execution at the same time, escaped from the tower in female apparel, through the excellent management of his wife. Sir Robert Walpole, who has been accused as a corrupt minister, declared, that £60,000 was offered to him if he could save the life of the earl of Derwentwater, but that he refused it. The last executions were lord Balmerino and lord Lovat for the rebellion of 1745, and Charles Ratcliffe, brother to lord Derwentwater, who suffered by himself on Little Tower Hill.

The military defence of London.—As far back as the reign of Alfred, the citizens of London were so imbued with the national spirit, that they were known amongst their fellow countrymen by the name of 'the brave Londoners.' When the patriot king was opposing a great body of the East Anglian Danes, who had thrown off his authority, and landed in the west of England from the north; the English army left London,

accompanied by a body of citizens, attacked the Danes under Hastings who had fortified Bampflete, overpowered the garrison, and carried off the wife and two sons of this celebrated chief.

In the reign of Ethelred the Londoners successfully resisted three attacks by the Danes; and thrice also was Canute repulsed when he laid siege to the city, nor did he ultimately gain possession of it, until, by a compromise with his rival, a division of territory was agreed upon. With equal spirit did the citizens refuse to admit William the Conqueror, when his arms had been victorious over Harold's army, until the clergy and the men of rank set the example of submission. It is true that Domesday Book, the oldest record of military service extant, does not mention the Londoners, but the reason of this is to be found in the peculiar nature of their civic privileges. The citizens did not, like other persons under the feudal system, hold their possessions by the tenure of military service; London was the 'king's own chamber,' where all were free, and all service was spontaneous. But, though not bound to furnish any particular quota of fighting men, the Londoners always mustered in great force, when an enemy was in the field; indeed it would seem from their numerous arrays, and the indiscriminate manner in which they turned out at every call to arms, that in early times every citizen was a soldier. We know that playing at bucklers, and practising feats of arms, was one of the most ancient and favorite amusements of the London apprentices. The *Ludus Trojæ* or Troy game, practised by the Roman youths, so called because it is said to have been derived from the Trojans, was also a favorite exercise with the citizens in the reign of Henry II. 'Every Sunday in Lent,' says Fitzstephen, 'immediately after dinner, it was customary for great crowds of young Londoners mounted on war horses, well trained, to perform the requisite turnings and evolutions, to ride into the fields in distinct bands, armed with shields and headless lances, where they exhibited the representation of battles, and went through a variety of warlike exercises.' He adds, that young noblemen from the king's court, and from the houses of the barons, often joined the citizens in the trial of their skill in arms. Numerous exploits are recorded, which attest the spirit and promptness with which the skill thus acquired was, in maturer life, exerted in the defence of the city and kingdom. During what are called the Barons' wars, in the reigns of Stephen, John, and Henry III., Fitzstephen says, that there went out of the city to a general muster no less than 20,000 horsemen and 60,000 foot; and though unquestionably there must have been included in these numbers many vassals of the noblemen, who had then castles and inns within the city, and of others who had sought the protection of its walls; yet it is clear, from the preponderance which the Londoners invariably gave to the party, whose cause they espoused at this period, that they must have constituted a very considerable portion of the force.

Often did the citizens contend in arms against the power that sought to oppress them in the

reign of Henry III., and on one occasion, Stowe relates, they 'fortified the city with iron chains, drawne overthwarte their streets, munited the cittie, and did marvellous things.'

The manufacture of armour must, at this period, have been very considerable; for when Louis the Dauphin contended for the crown of England against Henry III., in the year 1216, the city of London sent him 600 knights and 60,000 coats of mail.

In the time of Edward II., the queen having been refused admittance into Leeds Castle, Kent, the king called to him 'the commons of Essex and London,' by whose assistance it was speedily reduced; but, that this demand on the Londoners for military service might not be construed into an admission of their ordinary liability to such requisitions, the king, by his letters patent, declared 'that the circumstance should not be prejudicial to them, nor drawn into precedent for time to come.' Another event, which occurred shortly after, places the military independence of the citizens in a still stronger light. In 1326, when the queen had taken part with the barons, the king demanded from the citizens a supply of men and money. The answer they made was, that 'they would not go out of their city to fight, except they might, according to their liberties, return home again the same day before the sun-set.'

During the French wars, in the reign of Edward III., the quota of troops contributed by London was comparatively small. In 1346 they furnished only 100 men at arms, and 500 foot soldiers; and in 1355 twenty-five men at arms and 500 archers. Probably more were not required, for these wars were popular; and, on the triumphal entry of the Black Prince into London with the king of France, we are told that the citizens 'displayed with peculiar exultation, from their windows and balconies, the implements and ornaments of war.' 'On the breaking out of Wat Tyler's rebellion, in the ensuing reign, we have a remarkable instance of the strength in which the citizens could instantly muster, on any emergency. After Wat Tyler had been struck dead by the hand of Sir William Walworth, and while the king was amusing the rebellious multitude, by affecting to fill their leader's place, Walworth rode into the city, calling out aloud for succour for the king, when immediately 1000 well armed men obeyed the summons; and, being led forth in good array, spread such terror among the rebels, that they fled in all directions.

It is a singular fact, that, very shortly after the Londoners had thus distinguished themselves, their courage should for the first time stand impeached. When, in 1385, Charles II. of France made preparations to invade England, Stowe alleges that the Londoners 'trembling like leverets, fearful as mice, seek starting holes to hide themselves in, even as if the citie were now to be taken, and they that in times past boasted they would blow all the Frenchmen out of England, hearing now a vaine rumor of the enemies' coming, they run to the walls, break down the houses adjoining, destroy and lay them flat, and do all things in great fear, not one

Frenchman yet having set foot on ship-board. 'What would they have done,' he adds, 'if the battel had been at hand, and the weapons over their heads?' Froissart is supposed to afford some countenance to Stowe's aspersion, by remarking, that, when the French expedition was abandoned, the citizens, 'with a joy unexpressible, began to regale themselves and friends in a most sumptuous manner.' But is the invasion of our houses and firesides, by a foreign enemy, so little to be cared for, that even brave men should not rejoice at its being relinquished?

During the contest between the rival houses of York and Lancaster, the military defence of the capital became an object of great importance, and appears to have been duly appreciated. When the leaders of each party met in London in 1458, attended by a great number of their followers, in order to attempt a reconciliation, Sir Godfrey Boleyn, the lord mayor, kept watch daily with a guard of 5000 citizens completely armed; while three aldermen, with another body of 2000, continued the watch during the night.

The conduct of the citizens in the subsequent affairs of Jack Cade and Falconbridge, as before related, was such as showed that they had lost nothing of their ancient spirit.

Henry VII., having been very partial to archery in his youth, gave it every encouragement when he ascended the throne, in preference to the cross bow, although he sometimes amused himself with it, as we find by the following memoranda, in an account of his expenditure preserved in the Remembrancer's Office. 'Lost to my lord Morging, at the buttes, 6s. 8d.' and 'paid to Sir Edward Bourough, 13s. 4d.' which the kynge lost at buttes with his cross bow.' From these entries it would appear that the king was not so skilful a bowman as his sons, particularly the eldest, prince Arthur, who frequently exercised with the society of London bowmen at Mile End, and was so expert, that the captain, and every expert shooter, was called by his name.

The military art, and especially the practice of archery, continued to be cultivated as much as ever. At a general muster of 'the most able men between the ages of sixteen and sixty,' which took place twice by order of Henry VIII. in 1532; and again on the 8th of May, 1539, when there appeared no less than 15,000, 'all in bright harness:—' Most of the citizens of any quality or office,' Strype says, 'were clad in white satin or white silk coats, with chains of gold, and some had rich jewels.' The king expressed himself highly pleased with their martial appearance. From this period, archery, so long the pride and glory of the London citizens, fell into disuse, principally, no doubt, from the introduction of muskets. Hollinshed bewails, that in this time, we had 'given over that kind of artillery,' the long bow, in which, in times past, the chief force of England consisted; and bishop Latimer equally laments the change that had taken place. In his sixth sermon, he says, 'The art of shutyng hath been in tymes past much esteemed in this realme, it is a gift of God, and he hath given us to excell all other nations wyth-

all. It hath bene Godde's instrumente whereby he hath gyven us manye victories agaynste oure enemyes.' He then points out the necessity of calling upon the justices, and charging them 'upon their allegiance, that thys singular benefit of God may be practised.'

In the popular insurrection of the Kentish men, under Sir Thomas Wyatt, in the reign of Mary, the queen requested from the city an aid of 500 footmen, well harnessed, to go against the rebels. It was immediately granted, the men were made ready the same night, and on the morrow marched into Kent. It soon appeared, however, that their ardor sprung from another source than attachment to the queen; for after joining the royal forces under the duke of Norfolk, the Londoners went over in a body to the rebels, and their example was followed by more than three parts of the army, not excepting the queen's guard itself. The city, notwithstanding, still held out for her majesty, but probably owing more to its being temporarily placed under the command of lord William Howard, a devoted servant of the queen's, than to the loyalty of the citizens themselves, who participated largely in the discontent which Mary's marriage to Philip of Spain had excited.

In the second year of Elizabeth's reign, there was a muster of the citizens before her majesty, and the French and imperial ambassadors in Greenwich Park; but it seems, from the comparatively small number assembled, to have consisted of some select companies only. There were '1400 men, whereof 800 were pikemen, all in fine corslets, 400 harquebuts in shirts of mail with merins, and 200 halberdiers in almayne rivets; they had to every 100 two whifflers richly appparelled, and twelve wardens of the best companies, riding in coats of black velvet, to conduct them, with drums and fifes, and six ensigns, all in jerkins of white Bruges satin, cut and lined with black sarsnet, with caps, hosen, and scarfs according.'

When, in 1572, Elizabeth began to be disturbed in her government by machinations, foreign and domestic, she sent an order to the lord mayor, sheriffs, and aldermen, recommending to them renewed diligence in training up the young citizens to the use of arms for the defence of the capital; and particularly to the use of musketry, which was now beginning to supersede the bow and arrow. The order was obeyed with so much alacrity, that, within two months after a choice body of 3000 pikemen and gunners, completely armed and disciplined, mustered before the queen in Greenwich Park; and these were independent of the city archers, who were estimated to amount to 4000 more.

The preparation in the ports of Spain of the boasted Armada, which was to effect the conquest of England and the re-establishment of popery, called for still greater exertions on the part of the citizens of London. From a report of the arrangements made for the defence of the kingdom on that occasion, recently compiled from the records in the tower (printed, but not published), it appears, that London then contained 20,696 able householders within the wards, besides 933 strangers fit for service; and that of this number no less than 10,000 were actually embodied.

Although the lords of the council ordered Edmund York, a brave officer, who had served in the Low Countries, to point out the best means of putting the city in a good state of defence, yet the lord mayor had the supreme command and authority to appoint colonels, captains, and other inferior officers under him. 'Such an honor' says York, 'and such a gracious favor, never happened to any people, neither was the like heretofore done unto them.'

York recommended that the city should be divided into sections, containing 1500 men, 'all inhabitants, which shall be either the householder, his sonne, or continued servant.' Every night at six o'clock, five companies of different regiments were to assemble in the Exchange, 'and there stand in battell a quarter of an hour.' After the countersign was given to every officer, says York, 'a prayer for her majesty's estate and kingdom, and the Lord's prayer, shall be said.' Five billets were next to be put into a hat, which the captains were to draw, to determine their respective stations for the night. So much reliance had the queen upon the courage and attachment of the citizens, that she selected 9000 of them to be her body guard. The remaining 1000 were sent to the camp at Tilbury Fort.

The usual place of training the city bands at this period, was the old Artillery Garden or Ground, the site of which is commemorated by the names of several streets and lanes on the east side of Bishopsgate Street, as Artillery Street, Artillery Lane, Fort Street, &c. 500 of the most expert, who had 'experience both abroad and at home,' were selected to drill the rest, and we are told, that 'very sufficient and skillful they were to train and teach common soldiers the managing of their muskets, pikes, and balberds, march, counter-march, and ring.' These masters of the art military formed a company by themselves, of which 'every man by turn bore orderly office, from the corporal to the captain.' Some of these were sent to the camp at Tilbury, to assist in drilling the new levies, and were then known by the name of the captains of the artillery garden. Such was the rise of that respectable body, still subsisting at the present day, the Artillery Company.

The military ardor which the Spanish Armada called forth, was succeeded by a long period of ease. The whole of the city corps were disembodied, and the exercises in the artillery garden entirely discontinued; so that, when the queen wanted an aid of men from the city, to send to the relief of Calais in 1596, she was obliged to resort to the mode of impressment, and that in a way not attempted perhaps either before or since. On the forenoon of Easter Monday, the lord mayor and aldermen received orders to provide instantly, for the queen's service, 1000 able bodied men. The day and hour were conveniently chosen; the churches, as is usual on this festival, were filled; and thither the magistrates immediately repaired with their proper officers, made fast all the doors, and in a few minutes executed the required levy on the assembled congregations. 'The men were forthwith furnished with armour, weapons, and all things necessary,' and marched

off to Dover before night. The system of pressing, though not in the same indecorous manner, was afterwards repeatedly resorted to during Elizabeth's reign.

A material change in the military exercises of the London citizens took place at the close of Elizabeth's reign, with which the use of the sword and buckler seems to have ended. Stowe relates that, in his time, 'the art of defence and use of weapons was taught by professed masters,' and that the young Londoners, after the evening prayer on holidays, were permitted to exercise themselves with their wafers and bucklers before their masters' doors. The wafers here mentioned were swords with the flat part placed in the direction of the edge. Shakspeare and all the writers of his time mention schools for teaching the use of weapons as common in London; but when the alarm of outward danger had been dissipated, and the pusillanimous reign of James had commenced, military exercises were naturally discountenanced by a king, who had an instinctive horror at the sight of a naked sword; and who praised armour, rather because, as he said, it prevented the wearer from hurting others, than for the protection it gave him.

The danger which might arise from such an habitual neglect of military exercises, at length roused some patriotic spirits to exert themselves to revive the ancient trainings in the artillery garden. In 1610 Philip Hudson, lieutenant of the artillery company, and divers other gentlemen and citizens of London, considering the inconveniences which had been suffered by many 'late populous and flourishing neighbour cities, principally by reason of their neglect of that most noble exercise of arms and martial discipline in times of wealth and peace; they, like loving sons to so glorious a city,' undertook, 'at their own private or particular charge, a weekly exercise of arms and military discipline after the modern and best fashion and construction then in use;' and for their better ease and more convenience, 'they erected a strong and well furnished armoury in the said ground, in which are arms of several sorts; and of such extraordinary fashion and goodness for service, as are hard to be matched elsewhere.' Four years after, James I. commanded a general muster of all the horse and foot soldiers throughout England; and such was the progress which the citizens of London had by that time made in their military re-organization, that no fewer than 6000 of them assembled on the occasion. They were commanded by twenty captains, selected of the most active and forward citizens, and unto every one of them were allotted 300 shot and pikes, being, for the most part, all householders bravely furnished; and such of them as were not formerly of the Martial Society, and practice of the Artillery Garden, became then admitted of that warlike company.

Although the reign of James continued to the last undisturbed by war, the artillery company laudably persevered in their exercises. In 1638 the common council passed an order 'that the trained bands should be made perfect in discipline, and that the greatest care should be taken that low and indigent persons do not impose themselves as officers, but that they be selected

from the most respectable gentlemen, and also from those who are capable and expert.'

When the civil wars broke out, in the reign of Charles I., the trained bands of London, as they were then called, espoused the cause of the people, and are universally allowed to have contributed mainly to its ultimate triumph. After Charles made his rash attempt, in 1642, to seize on Pym, Hampden, and the other obnoxious members of the house of commons, whom he had caused to be accused of high treason; and when these champions of liberty took refuge in the city, and the grand committee of parliament itself was obliged to transfer its sittings to Guildhall, the trained bands placed themselves under the command of major general Skipton, for the purpose of protecting them in the exercise of their parliamentary privileges.

The appeal to arms was at length made, and Charles advancing towards London, defeated colonel Hollis's regiment at Brentford, and took possession of that town. Every possible exertion was then made to prevent his entrance into the capital; 'with unspeakable expedition,' says Clarendon, 'the army, under the earl of Essex, was drawn together, and the trained bands of London led out, in their brightest equipage, upon the heath next Brentford, where they had, indeed, a full army of horse and foot, fit to have decided the title of a crown with an equal adversary.' The parliamentary forces did not amount to less than 24,000 men, 'stout, gallant, proper men, as well habited and armed, as were ever seen in any army, and seemed to be in as good courage to fight the enemy.' 'The good wives and others,' says Whitelock, 'mindful of their husbands and friends, sent many cart loads of provisions, and wines, and good things to Turnham Green, with which the soldiers were refreshed and made merry, and the more, when (after a short time) they understood that the king and all his army were retreated.' Next year the citizens not only repaired and strengthened their walls, but erected an outer line of trenches and fortifications, which included the whole of the suburbs from the end of Shoreditch on the east, to Hyde Park Corner and Vauxhall on the west, and from the end of Kent Street, Deptford Road, on the south, to Bloomsbury on the north. Nothing could exceed the ardor with which these fortifications were prosecuted. Thousands of men, women, and children, assisted by the train bands, and headed by several members of the common council, were constantly at work. The different trades went out in a body on alternate days, as appears by the statements in the 'Diurnals,' and other newspapers of the time. One day, between 2000 and 3000 porters gave their labor, another day 4000 or 5000 shoemakers left their gentle craft to assist in the new fortifications; and the tailors, to the number of 6000, lent their willing and unsolicited aid to the same purpose. The fortifications consisted of a strong earthen rampart, planted with bastions and redoubts. The expense of these works was defrayed by a general levy on the inhabitants, and a loan of £60,000 from the city companies.

The king's affairs taking for a time a prosperous turn, and the city of Gloucester, which had de-

clared for the parliament, being hard pressed by his troops, great exertions were made to send the earl of Essex with an army to its relief; and to encourage the recruiting, for this purpose, the London magistracy had recourse to the vigorous measures of ordering, that all shops, within their lines, should 'be shut up, and continue so till Gloucester was relieved.'

The Londoners accordingly, besides furnishing two regiments of their trained bands, sent forth four auxiliary regiments, three of foot and one of horse. The parliamentary army now marched towards Gloucester, but the king, hearing of their approach, raised the siege and advanced to meet them. The hostile forces met at Newbury, and in that sanguinary fight (albeit they were but keepers of shops), gave signal proof of their hereditary resolution and prowess. 'The London trained bands and auxiliary regiments,' says lord Clarendon, 'of whose inexperience of danger or any kind of service, beyond the easy practice of their postures in their artillery garden, men had till then too cheap an estimation, behaved themselves to wonder, and were, in truth, the preservation of that army that day; for they stood as a bulwark and rampire to defend the rest, and, when their wings of horse were scattered and dispersed, kept their ground so steadily, that though prince Rupert himself led up the choice horse to charge them, and endured their storm of small shot, he could make no impression upon their stand of pikes, but was forced to wheel about.' In the subsequent affair at Cheriton Downs, the Londoners acquired fresh laurels. Two of their strongest auxiliary regiments fought under Sir William Waller, on that occasion, and, as Whitelock tells us, 'did very brave service; they drove the enemy from the hedges, which they had lined with musketeers, and gained the passage to a wood, which stood the parliamentary forces in great stead, and shortly after put the enemy to a rout; which was so total, that scarcely ten of them were left together.'

The city shortly after increased the number of troops they had in the field against the king to 8400; four regiments were under the earl of Essex, and three under Sir William Waller.

Although they continued foremost, in the struggle between the crown and the people, the Londoners, when the parliament and the army quarrelled, and Cromwell rose on the bucklers of the latter to supreme power, fell into the back ground, and suffered but too many affronts and hardships at the hands of those whom they had been the principal means of placing in the seat of royalty. The works about the city were ordered to be demolished; the trained bands were discharged; the treasuries of different city companies were robbed, in order to pay arrears due to Cromwell's soldiers; particularly that of the weavers' company, from which £20,000 were carried off; and, when these were found insufficient for the purpose, bands of these satellites were quartered on the city, not only in the inns, but in private houses, till the deficiency was made up.

During the quarrel between the army and the parliament, the services of the London trained bands were frequently called for to suppress tumults: nor were those of a political nature the

most dangerous to the existing government. In April, 1648, a riot was begun in Moorfields, on account of the infraction of the parliamentary ordinance against tippling and gaming on the sabbath, which required all the energy of Fairfax to suppress. The first party of the trained bands sent to quell the tumult were overpowered by the rioters, who seized their arms, drums, and colors, and daringly beat up for recruits. A mob in a populous city is like a rolling snow ball, increasing as it proceeds; and the rioters were soon so formidable as to be enabled to act on the offensive. The prisons of Newgate and Ludgate were surprised during the night; and next day they attempted to seize Whitehall, but were repelled by the soldiers. They, however, were more successful in the city, where they attacked the mansion house, and carried off a piece of artillery, called a drake. Ammunition was obtained from the magazine, in Leadenhall Street, where they made a stand against the only two regiments then in London, nor did they give way until several of them were wounded, and others taken prisoners.

When the question of the restoration came, after the death of Cromwell, to be agitated, the citizens had their revenge. The king's restorer, Monk, found them well disposed to second his views, and, being appointed major general of their forces, he speedily re-embodied both the trained bands and auxiliary regiments, and, at a grand review in Hyde Park, appeared at the head of no fewer than 18,600 'brave Londoners,' a greater force than the city had mustered for some centuries. It was composed of six regiments of trained bands, six auxiliary regiments, and one regiment of horse. The mere demonstration of such a force, on the order of royalty, at this juncture of affairs, was sufficient. The restoration immediately followed.

Very shortly after, the restored monarch issued a commission of lieutenantancy for the city of London, which vested the commissioners with similar powers to those possessed by the lords lieutenant of counties. The city regiments were by them new modelled, and augmented, the foot to 20,000, and the horse to 800.

The insurrection of the fifth-monarchy men, which took place in the following year, is justly regarded in history as an act of frenzy in a deluded few; but it deserves notice here, as a sort of frenzy which could only have happened in a community injured, as we have seen that of London was, to the use of arms. A body of not more than sixty men, but all well armed, sally forth from a meeting house in Swan Alley, Coleman Street, under the guidance of one Venner, their preacher, and a mad colonel of the name of Cox, to proclaim 'King Jesus.' They encounter a party of the trained bands, in the interest of 'king Charles,' led on by Sir Richard Brown, the lord mayor, and put them to the rout. They march triumphantly up and down the city, kill a headborough by way of exercise, and then, learning that a body of horse is coming against them, retire for the night to Caen Wood, near Hampstead. Here they are attacked at break of morn; some of them are taken, and the rest dispersed. But next day they rally, return into the

city, and fight a severe battle in Wood Street, with a body of regular horse and a party of the trained bands; two of their best men are slain, and Venner, the leader, wounded and made prisoner; the remainder, under colonel Cox, retire fighting towards Cripplegate: a party of ten take post in a neighboring ale house, and defend it with such resolution, that it is not carried before seven of them are killed; nor until twenty of the whole number, being at least more than the one-half, and twice as many of their opponents, have apparently bit the dust.

The trained bands, 'of whose inexperience in danger, or of any kind of service beyond the easy practice of the artillery garden,' Clarendon says, 'men had too cheap an estimation,' were long the favorite force of the metropolis; and on every occasion, when their services were called upon, proved themselves worthy of the confidence of their fellow citizens. Previous to the civil war, as appears by a tract in the Harleian MSS., containing an account of their musters in 1643, their force, including auxiliaries, exceeded 18,000 men. This species of force, which was neglected during the protectorate, was remodelled by Charles II., and the trained bands alone augmented to 20,000 men. As the restored government found itself secure, this force was reduced, and may be said to have been almost disorganised, when the rebellion of 1715 induced the government to issue an order for it to muster, and be in readiness to suppress any tumults that might arise. The trained bands were still nominally kept up, although six auxiliary regiments and some troops of horse were reduced.

The rebellion of 1745 again roused the military spirit of the metropolis: the trained bands were kept in readiness, and the militia embodied; two regiments were raised at the expense of the merchants, and corps of volunteers incorporated. The lawyers exchanged their briefs for muskets, and the judges their wigs for helmets; the weavers of Spitalfields laid aside their shuttle and distaff for the pike and the bayonet; and even the managers of the theatres offered to form a corps of 'his majesty's servants,' ready to quit the mimic combats of the stage for the tented field. Large subscriptions were raised for supplying the troops with the necessary clothing and the munitions of war, towards which the corporation of the city gave £1000, and several of the city companies contributed liberally. Even the Quakers so far overcame their religious scruples as to raise a considerable sum for the purchase of woollen waistcoats for the soldiers; and, had the danger been more imminent, it is probable they might have been induced to go farther, and, like the Quakers of America at the commencement of the revolution, have subscribed for gunpowder, under the equivocal denomination of grain, or for muskets, under the name of fire irons. The approach of the rebels to Derby increased these preparations: the city gates were guarded; and a large train of artillery was sent from the tower to a camp formed on Finchley Common, where it was determined to raise the royal standard. This circumstance gave rise to Hogarth's admirable picture, the March to Finchley, for which he sought the royal patronage; but the king, who saw

nothing in the picture but that his soldiers were ridiculed, expressed great displeasure; and the print was dedicated to the king of Prussia.

An age of tranquillity succeeded, and the military force of London was kept up more for parade than service, until the French revolution broke out. As the danger approached, the necessary preparations were made with zeal and alacrity. It was at first proposed, that two regiments of militia should be raised by ballot, and placed under the commission of lieutenantancy; but this mode was found inconvenient; and in 1796 a new act of parliament was passed, authorising the city to raise two regiments of 600 men each, by enlistment, the expense of which was to be defrayed by a small assessment on each ward. Each regiment was commanded by a colonel, lieutenant-colonel, major, ten captains, ten lieutenants, and ten ensigns, all appointed by the great officers of the city, who formed the commission of lieutenantancy. The authority of the crown over the two militia regiments was very limited. His majesty could only order one regiment to march out of the city, and that not further than a distance of twelve miles. The success of the French arms in Italy and Germany, and the threatened invasion of Great Britain, redoubled the military ardor, and volunteer associations were raised in every part of the kingdom. In London they consisted principally of citizens, and other respectable tradesmen, who formed themselves into companies in their respective wards and districts, electing their own officers, finding their own clothing, arms, and accoutrements, and devoting their time and their money to the service of their country. These military preparations were very actively carried on in the year 1798.

The anniversary of the birth of his late majesty was celebrated on the 4th of June, 1799, by one of those spectacles which a free country could alone present. His majesty on that day reviewed 15,000 men, of whom upwards of 8000 were citizen soldiers, who had, from motives of the purest patriotism, formed themselves into military associations, and relinquished for a moment their peaceful occupations, to learn 'the trade of war,' at their own expense, for the purpose of guarding their own and their sovereign's rights, should they have been attempted to be endangered by the threatened invasion. After the troops had gone through their evolutions, much to the satisfaction of his majesty, and the firing was concluded, the whole line waved their caps in the air, and gave three hearty huzzas, which were echoed and re-echoed by upwards of 150,000 persons who attended the review.

The military spirit and patriotism of the city of London had not yet, however, fully developed itself. Every year, every month, and we might say every day, increased the loyal associations of which the nucleus only had as yet been found. In the month of October, 1803, a succession of reviews took place, in which more than 30,000 volunteer troops were reviewed; and this number, large as it was, fell far short of the actual force of the metropolis, which, including a few of the adjacent villages within the bills of mortality where distinct corps had also been formed

amounted to a force of 46,000 men. His royal highness the duke of York, the commander in chief, observed, in his general orders, 'His majesty perceives, with heart-felt satisfaction, that the spirit of loyalty and patriotism, on which the system of the armed volunteers throughout the kingdom was originally founded, had risen with the exigencies of the times; and at that moment formed such a bulwark to the constitution and liberties of the country as will enable us, under the protection of providence, to bid defiance to the unprovoked malice of our enemies, and to hurl back, with becoming indignation, the threats which they have presumed to vent against our independence.' At the peace of 1814 the military force of the metropolis was reduced to the artillery company and the two regiments of militia which had superseded the trained bands.

CHURCHES, PUBLIC BUILDINGS, &c.—We may now advert to the buildings of this great metropolis, and of these, the churches of the establishment, necessarily, take the lead, on account of their magnificence, as well as their antiquity.

The *cathedral of St. Paul's* is the noblest of Protestant churches. Some historians endeavour to prove that it occupies the site of an ancient temple of Diana: but this Sir Christopher Wren discredits; observing that 'having changed all the foundation of old St. Paul's, and upon that occasion rummaged all the ground thereabouts, being very desirous to find some footsteps of such a temple, he could not discover any.' It is not before the time of Augustine we find any trace of a structure here. When he found a patron in Ethelbert, king of Kent, this monarch, in 1619, first founded the cathedral, dedicated it to St. Paul, and endowed it with the manor of Tillingham and other lands. It was of wood; but for the period no mean structure: Dugdale assures us that, in 1675, Erkenwald, then bishop of London, 'bestowed great cost on the fabric thereof, augmenting its revenues very much with his own estate.'

During the heptarchy, this church flourished. Kenred, king of Mercia, declared it to be as free in all its rights as he himself desired to be at the day of judgment. Athelstan endowed it with 106 farms, messuages, &c. Edgar gave it twenty-five mansions, besides a considerable sum in money; and his wife, Eglefleda, two lordships. All these grants were confirmed by the charters of Ethelred and Canute, which solemnly denounce curses on all who dare to violate this place of worship. Edward the Confessor, also, endowed it liberally, so that 'great was the esteem that this cathedral then had.' On the landing of William I. he seized on some of the revenues of St. Paul's; but no sooner was he seated on the throne than he restored them, and confirmed all its privileges.

In 1086 the wooden cathedral was laid in ashes, by a conflagration which destroyed the greater part of the city; but this event made way for a more magnificent building than had ever been raised for the purposes of devotion in this kingdom. To the pious zeal of the bishops, Maurice and De Belmeis, London was chiefly indebted for this new edifice. The latter is said

to have devoted the whole of his revenue to this undertaking. The steeple, which was of timber, was finished in 1221; the quire in 1240; and, in 1283, the cathedral, nearly as it stood in point of magnitude previous to the great fire, was finally completed, with the exception of the pavement, which was not made until the year 1312, when the whole was paved with 'good and firm marble, which cost five-pence the foot.' About this period an exact survey was made of the church; and its dimensions, according to Dugdale, were stupendous.

In length it measured 690 feet; and in breadth 130 feet; the height of the body of the church was 150 feet; and the space of ground comprehended within the walls was three acres and a half, one rood and a half, and six perches. The height of the tower and spire from the level ground was 520 feet: the ball, above the head of the spire, was so large, that it would contain within it ten bushels of corn; the length of the cross, above the ball, or pomel, was fifteen feet; and the traverse of the cross six feet.

Dugdale enumerates no fewer than seventy-six chantry chapels within this sacred fane, and sixty endowed anniversary obits: not fewer than 200 priests are supposed to have been required to perform the various duties of these establishments.

The building was in the Norman style, and is supposed to have presented one of the earliest and finest examples of the use of pointed arches. The decorations within, corresponded in richness and splendor with the magnificence of the exterior. The high altar shone all over with precious stones, and was surrounded with images, 'beautifully wrought.' At the right side of it there was an oil painting of St. Paul, 'placed in a tabernacle of wood,' which is said to have been a masterly performance, having been executed in 1398, at a cost of £12 6s. Near the altar was the splendid shrine of St. Erkenwald, which was for many ages a favorite resort of the pious. Another shrine, nearly as celebrated, was that of Roger Niger, who was made bishop in 1229; Matthew Paris records, that miracles were frequently wrought at it.

Among the uncanonised, but perhaps not less truly eminent personages, to whom monuments were erected in this cathedral, were 'old John of Gaunt, time-honored Lancaster;' the gallant Sydney, author of the *Arcadia*; Dean Colet, the founder of St. Paul's school; and Vandyke, the painter. Here too reposed the ashes of Sir Francis Walsingham, but without a stone to mark the spot. He died so poor that his body was buried by stealth, to prevent its being arrested. The celebration of obsequies for persons of rank once formed a peculiar and a very profitable privilege of St. Paul's. The ambassadors of foreign princes, and many of our nobility, according to Dugdale, the knights of the garter, the lord mayor, and the several companies of London, all attended with great devotion at these ceremonies.

St. Paul's was the place where, in the reign of Edward III., the flagellants, to the number of 120 men and women, exercised their castigations. 'Each day,' says Dr. Lingard, 'at the appointed

hour, they assembled, ranged themselves in two lines, and moved slowly through the streets, scourging their naked shoulders, and chanting a hymn. At a known signal, all, with the exception of the last, threw themselves flat on the ground. He, as he passed by his companions, gave each a lash, and then also lay down. The others followed in succession, till every individual, in his turn, had received a stroke from the whole brotherhood. The citizens gazed and marvelled, pitied and commended; but they ventured no farther.'

After the battle of Bosworth-field, which gave the crown to the earl of Richmond, the king, on arriving in London, rode through the city to the cathedral church of St. Paul (says a MS. in the Lansdown collection, No. 250), where he offered three standards.

On the 6th of April, 1592, the nobles, with the lord mayor and corporation, attended St. Paul's in great state, when Dr. Morton, archbishop of Canterbury, and lord chancellor, addressed them in a long oration, on occasion of the king of Spain having taken Granada from the Moors. *Te Deum* was sung and great rejoicings followed.

Queen Mary seems to have had particular attention paid to her at St. Paul's. On one occasion, when the queen rode through the city to Westminster, as she passed through the churchyard, a Dutchman of the name of Peter stood on the weathercock, holding a streamer in his hand, five yards long, and, waving it, stood some time on one foot, at the same time shaking the other; 'and then,' says Stowe, 'kneeling on his knees, to the great marvail of all the people.' The city gave him twenty-five marks for his 'cost and paines.' On her marriage with Philip of Spain, when the king and queen passed the churchyard, 'a fellow,' says Stowe, 'came slipping upon a cord, as an arrow out of a bow, from Paul's steeple to the ground, and lighted with his head forwards on a sort of feather bed, and after he climbed up the cord again, and did certain feats,' all of which were repeated on the coronation of Edward VI.

Old St. Paul's was the scene, however, of far more important ceremonies. It was here that the pusillanimous king John signed the resignation of his crown and kingdom to the haughty legate of the pope. Here, too, queen Elizabeth publicly returned thanks to the Deity, for the victory over the Spanish armada; and the colors taken from the enemy still stream in triumph, under the dome of the cathedral.

In the reign of Philip and Mary, we find that the cathedral was a place of common resort and thoroughfare; and that, not only porters and carriers of goods, but beasts of burden were suffered to pass through it. The dean and chapter, too, instead of checking this concourse, turned it to their profit, by imposing a toll on each passenger. The abuse at length became so flagrant, that an act of common council was issued to restrain it. Many shops, and houses too, were built against the outer walls of the cathedral; and even a playhouse is said to have been among the erections here.

The Burnynge of Paules Church in London,

an old tract written in the year of our Lord 1561, points out the different places where business of various sorts were carried on. 'The south alley for usury and popery; the north for simony and the horse faire; in the midst, for all kind of bargains, metinges, brawlings, murders, conspiracies; and the font, for ordinary paiement of money, are so well known to all menne, as the beggar knows his dishe.'

The simony and trading in benefices, carried on in St. Paul's, appears to have been long known. Chaucer alludes to them in the prologue to his *Canterbury Tales*, and bishop Hall, in one of his satires, broadly mentions them as notorious. Advertisements were openly posted on the doors for the sale and purchase of benefices, beginning usually with the words *Si quis*, a circumstance thus alluded to by bishop Hall:—

Saw'st thou ever *Si quis* patch'd on Paul's
church door,
To seek some vacant vicarage before?
Who wants a churchman, that can service say,
Read, fast and faire, his monthly homiley,
And wed and bury, and make Christian soules?
Come to the left side alley of Saint Paul's,
Thou servile foole.

The description of the satirical bishop has many illustrations: 'I bought him in Paul's,' say Falstaff, in speaking of Bardolph. Massinger also, in his *City Madam*, thus alludes to it as: 'notorious thieves' sanctuary.

'Dining with duke Humphrey' was applied at this time, to persons who walk about for lack of a dinner to sit down to. 'Are they none of duke Humphrey's furies? Do you think the Devised this plot to get a dinner?' (*Mulco's Midnight*.) That is, one of the aisles of St. Paul's was called duke Humphrey's Walk, from a popular notion, that the good duke Humphrey of Gloucester was buried there; though the fact is, that the duke was buried at St. Alban's, and the monument which the vulgar supposed to be erected to his memory was one placed over the remains of Sir John Beauchamp, son of Gu Beauchamp, earl of Warwick.

We cannot here detail the further history of the old building. Large sums of money were collected under king James I. commission, and considerable quantities of building material actually provided for its repair; but the reign of James elapsed without the work being commenced. The duke of Buckingham is said to have borrowed some of the latter for the erection of the water gate at York House. On the appointment of Laud to the see of London, this prelate exerted himself with great vigor and success in favor of the neglected building, and set on foot a new subscription, which produced in a short time £101,330 4s. 8d. The celebrated Inigo Jones was employed to superintend the repair; but, before any thing material was effected, the great fire came, and reduced it to a heap of ruins.

The subscriptions for building a new cathedral which commenced soon after the fire, amounted in the course of ten years, to £126,000; a new duty was laid on coals for the same purpose which produced £5000 a year; and king Charles I. contributed £1000 annually. Wren was

ordered to prepare designs for the inspection of the king, and, fixing upon one of them, his majesty commanded a model of it in wood to be prepared on a large scale. Of this model, which is suffered to remain in a dilapidated state in an apartment in the cathedral, where it is exhibited, a living architect (Mr. Elmes) says, 'it possesses an originality peculiarly striking; copied from no other building, it exhibits judgment and invention in every turn.'

Excellent as the plan was, it was rejected, on the ground that it differed too much from the preconceived notion of cathedral churches; the secret appears to have been, that it was not adapted to the ceremonies of the Roman Catholic church, which the duke of York hoped to restore, and therefore he used his influence to get the plan rejected. It was with the same view that the duke obtained the addition to the plan that was adopted, of the side oratories, which so much broke in upon the design, that the architect is said to have shed tears when he was compelled to admit them.

The commission for rebuilding the cathedral was issued under the great seal, dated November 12th, 1673. The business of taking down the ruins of the old structure was one of considerable labor and difficulty. To the middle tower, the ruins of which were 200 feet high, a blast of eighteen pounds of gunpowder was applied, under the direction of the architect; and, comparatively small as this force was, it raised the whole angle of the tower, with several adjoining arches; visibly lifting the vast mass, which was not less than 3000 tons in weight, about nine inches, when, tumbling back again suddenly, it dropped into a heap of ruins, but with such a concussion, that the inhabitants in the neighbourhood took it for an earthquake. Sir Christopher also now resorted to that ancient engine of war, the battering-ram; a beam of timber forty feet long, well secured with ferrules, and suspended from a triangle, was vibrated by thirty men for a whole day against a part of the wall without any apparent effect, but on the second day the whole was thrown down.

The first stone of the new cathedral was laid on the 21st of June, 1675, by the great architect himself, who lived to see his son, then only a few months old, thirty-five years afterwards, deposit the highest stone of the lantern on the cupola.

In 1693 the walls of the new choir were finished, and the scaffolding removed; and on the 2d of December, 1697, it was opened for divine service, on occasion of the thanksgiving for the peace of Ryswick. The morning prayer chapel was opened for divine service the 1st of February 1699. It is remarkable that this mighty fabric was begun and finished by one architect, Sir Christopher Wren; one principal mason, Mr. Strong; and during one bishopric, that of Dr. Henry Compton, bishop of London.

The total expense of the building was £736,752 2s. 3d.

The dimensions of this cathedral, compared with that of St. Peter's, are, according to the Parentalia, as follows:—

	St. Pau's.	St. Peter's.
Length within	. 500	669ft.
Greatest breadth	. 223	442
Height 340	432

In the construction of the edifice, the architect was forced to observe the general shape of a cross, and yet it exhibits little or none of the awkwardness of that form of building. By means of an additional transept or arm he has given due breadth to the west end or principal front; the east end terminates in a projecting semicircle; and at the extremities of the principal transept there are also semicircular projections for porticos, while the angles of the cross are occupied with square appendages, which serve as buttresses to a magnificent dome or cupola.

The front of the building on the west presents a grand portico of the Corinthian and Composite orders, surmounted by a spacious pediment, with a lofty tower or steeple of great elegance and richness on each side. In the tympanum, the conversion of St. Paul has been well sculptured in basso relievo, by Birt; on the apex is a colossal statue of St. Paul, and on either hand, at different distances along the summit of this front, are similar statues of St. Peter, St. James, and the four evangelists. The semicircular porticos at each end of the principal transept are of the Corinthian order, and are also crowned by statues of the apostles. The tympanum of that on the north side, exhibits a sculpture of the royal arms and regalia, supported by angels; and that of the other the phoenix rising from the flames, as before mentioned. The side walls of the building present the appearance of a two storied structure; there being two ranges of pilasters all round, one of the Corinthian, and the other of the Composite order; the intervals between which are occupied with windows. The dome or cupola is the most striking feature of the whole edifice. A plain circular basement rises from the roof of the church to the height of twenty feet; above that there is a Corinthian colonnade of thirty-two columns; and every fourth intercolumniation is filled with masonry, so dispersed as to form an ornamental niche or recess, while, at the same time, the projecting buttresses of the cupola are thus concealed. The entablature of the peristyle supports a handsome gallery surrounded with a balustrade. Within this rises an attic story, with pilasters and windows, from the entablature of which springs the exterior dome. Round an aperture on the summit of the dome there is another gallery, from the centre of which ascends an elegant lantern, surrounded with Corinthian columns, and surmounted by a ball and cross richly gilt. When viewed, especially, from any of the heights round the metropolis, such as Hampstead, or Highgate, or Shooter's Hill, its dome has a very noble appearance; though there, perhaps, it is rather to be regarded as a cupola to the vast metropolis itself, than to any single edifice. 'Considered in this light,' as Mr. E. Aikin remarks, 'the coldest critic, the most rigid theorist, could not wish to subtract a particle from its rich exuberance.'

The adoption of the two orders of architecture,

it must be remembered, was a matter not of choice but necessity. The quarries of the Isle of Portland, from which alone the stones for the building could be procured, could not furnish blocks of magnitude enough to enable the architect to raise his series of pillars all of one order; that is, to make the lowest order of the necessary elevation.

On entering the building, there is one discrepancy which strikes a stranger more forcibly than any that can be remarked in the exterior. Contrary to what he has been led to expect, from the division of the walls on the outside, into two stories, he finds no such corresponding division within. Although disappointed, however, he is far from being displeased. The unexpected loftiness of the vaulting, and of the long range of columns and piers which burst on the sight, add still farther to those ideas of vastness and magnificence which the exterior has inspired. Sir Christopher chose the hemispherical manner of vaulting, as being 'demonstrably much lighter' than diagonal cross vaults; and that demonstration we have here before us. 'The whole vault of St. Paul's consists of twenty-four cupolas, cut off semicircular with segments to join to the great arches, one way, and which are cut across the other way with elliptical cylinders to let in the upper lights of the nave; but, in the aisles, the lesser cupolas are both ways cut into semicircular sections, altogether making a graceful geometrical form (distinguished by circular wreaths.)'—*Parentalia*.

The great dome over the central area is supported by eight stupendous piers, four of the arches formed by which open into the side aisles. It has been so constructed as to show a spacious concave every way; and, from the lantern at the top, the light is poured down with admirable effect over the whole, as well as through the great colonnade that encircles its basement. The inside is divided into light compartments, in which there are as many paintings of subjects from scripture, by Sir James Thornhill; but, though originally executed with much animation and relief, the colors are now so faded, that they present to the eye of the observer below only a confused mass of stains. Sir Christopher Wren wished to have beautified the inside with the more durable monument of mosaic work; but in this, as in other instances of correct foresight, he was unhappily over-ruled. The choir is separated from the body of the church by handsome iron railings. Over the entrance to it is the organ gallery, and an organ in it supposed to be one of the finest in the kingdom. It was erected in 1694 by Bernard Schmydt, or Smith, for £2000. On the south side of the choir is a throne for the bishop; on the north another for the lord mayor; and, besides these, there is on each side a long range of stalls. The whole are richly ornamented with carvings. In the chancel, or semicircular recess at the east end, stands the communion table. What is called the altar piece, has four fluted pilasters painted in imitation of lapis lazuli, and is besides ornamented with a profusion of gilding; but its appearance is on the whole insignificant. It is due, however, to the memory of Wren to notice, that he had

other designs for this part of the building than those which have been realised. The pulpit and reading desk are both splendid objects; the former was designed by Mylne, and is richly carved and gilt; and the latter consists entirely of brass gilt, and is very light and airy. In the south end of the western transept there is a chapel for morning prayers, and in the north the consistory; both are divided from the aisles by screens of insulated columns, and ornamental carved work.

In the spaces between the great pilasters of the nave, Sir Christopher Wren has omitted inserting, as is usual, the architrave and frieze of the order, and this apparently for the purpose of raising the summits of the arches above the level of the architrave. We learn from the *Parentalia*, however, that he did not consider this to be any deviation from the strict rules of art; he always insisted that he had the ancients on his side, and would refer to the Temple of Peace, to the great halls of the Baths, for proofs that in large structures of three aisles this is done, and for this reason, that, in such wide inter-colunimations, 'the architrave is not supposed to be from one great column to another, but from the column to the wall of the aisle, so that the end of it only will appear upon the pillar of the inside of the great navis.'

In 1773 Sir Joshua Reynolds made an offer from himself, and a number of other painters of the first eminence, including West, Barry, Cipriani, Kauffman, Dance, &c., to paint various pictures, free of charge, to adorn the naked walls; but the offer, so honorable to them, was declined, on the ground (which, considering the Protestant riots of a later period, cannot be considered as altogether fallacious), that popular clamors would be excited by the idea, that 'popery and the saints were again to be admitted into our churches.' At a later period, a proposition for the introduction of monumental sculptures was attended with more success; and, considering that the same objection scarcely applies to them, it is surprising that it should not have been made earlier.

The first statue erected in St. Paul's was that of our great lexicographer, Dr. Johnson. Since then, about forty other monumental tributes to the illustrious dead of this country have been added; and, being all of white marble, and generally well distributed, they unquestionably contribute greatly to the relief and embellishment of the architecture. The monuments have in themselves, however, little to boast of.

It is due, at the same time, to the artists, to observe, that there is but too much reason to think that they have not always been allowed the free exercise of their own judgments, but have been often obliged to embody the gross conceptions of ignorant committees of superintendence and direction. When the dean and chapter first came to the resolution of admitting monuments into the cathedral, they resolved that no monument should be erected without the design being first approved of by a committee of the Royal Academicians; but it is asserted, that, 'from the influence of some unexplained imperium in imperio, the ultimate decision was not intended to be given to the committee.' A vindicator of

Chantrey from his share in the allegorical mania, says, that the design in which it occurs was made entirely in deference to the powers who sit in judgment on these occasions, and under the certain conviction, that without submission to the prevailing taste his model would have been thrown aside, as he had before repeatedly experienced.—Britton's Illustrations of the Public Buildings of London.

But few of the persons to whom monuments are erected in the cathedral, have been really buried here. Among the number, the first who claims our notice is the great architect of the building, Sir Christopher Wren. Descending to the vaults by a broad flight of steps, you see beneath the south-east window, inscribed on a low tomb, the following simple epitaph: 'Here lies Sir Christopher Wren, Knight, builder of this Cathedral Church of St. Paul, who died in the year of our Lord MDCCXXIII., and of his age XCI.' On the wall, above, there is an additional inscription in Latin, with which the public are more familiar, and which may be thus translated: 'Beneath lies Christopher Wren, the builder of this church, and of this city, who lived upwards of ninety years, not for himself, but for the public good. Reader would'st thou search out his monument? Look around. He died 25th February, 1723, aged ninety-one.'

At the suggestion of the late Mr. Mylne, the architect, it has been repeated on a tablet in front of the organ gallery in the choir; yet even there the effect is incomplete. Considering that Wren was in truth the builder, both 'of this church and this city,' the reader should be enabled, to 'look around' on both, to behold 'his monument.'

In these vaults, also, repose the mortal remains of the immortal Nelson, and of his friend and companion in victory, Lord Collingwood, both of which were deposited here with all those funeral honors which a sorrowing country could bestow. Here too lie interred those eminent masters Reynolds, Barry, and Opie, in contiguous graves; the eloquent and sagacious Loughborough; the learned and pious Dr. Newton, bishop of Bristol; Dr. Boyce, the organist and composer; the eccentric disciple of animal magnetism, Mainan-dot; and a few others of inferior note.

After examining all that is to be seen in the lower part of the cathedral, the visitor has still to make the ascent to the summit, to examine the interior of the vast dome, and to enjoy the magnificent views, which the outside galleries furnish of this vast metropolis. You ascend by a spacious circular stone staircase, to a gallery which encircles the lower part of the interior of the dome, and is called the whispering gallery, from the circumstance, that the lowest whisper breathed against the wall, in any part of this vast circle, may be accurately distinguished by an attentive ear on the very opposite side. The paintings within the dome, you find, even on this nearer inspection, scarcely distinguishable. All the lower parts have perished utterly, and the rest are in a state of rapid obliteration. The subjects were all chosen from the life of St. Paul, as recorded in the Scriptures, from his miraculous conversion near Damascus, to his shipwreck at Melita.

Branching off from the circular staircase, at this place, there are passages which lead to other galleries and chambers over the side aisles. One conducts you to the Library of the chapter, which is immediately over the consistory. The floor of this apartment is a great curiosity, being entirely constructed of small pieces of oak, without either nail or peg, and disposed into various geometrical figures, with the utmost nicety. Above the chimney there is a good half length portrait of the protestant bishop Dr. Compton, who bequeathed the whole of his books to the library, which is not however of much value as a collection. Over the morning prayer chapel, at the opposite end of the transept, is a room called the Trophy Room, from being hung round with various shields and banners used at the ceremony of Lord Nelson's funeral. In this room are kept the rejected model, according to which Sir Christopher Wren first proposed to erect this cathedral, and also the unexecuted model of the altar piece. From the whispering gallery, the visitor ascends to the stone gallery, which surrounds the exterior dome above the colonnade; and from this elevation, when the atmosphere is clear, the view around is magnificent. As the staircase above this becomes very steep, narrow, and dark, not many visitors can prevail on themselves to go higher; and yet there is much to repay both the trouble and apprehension attending the ascent. In the crown of the dome there is a circular opening, from which the superstructure of the cone and lantern, and cross, rise nearly 100 feet higher. Around the exterior base of the cone there is a railed gallery, called the golden gallery, from which you have a more extended, and, on account of the increased diminution of individual objects, a more curious view of the busy world beneath. If your head is steady enough to master the feeling of dizziness which overpowers most people at so great an elevation, and makes them feel that the only pleasure in going up is the pleasure of coming down again, you may even ascend by ladders into the lantern itself, and, from the bull's eye chamber, extend your survey far into the country on every side. Here did a most ingenious and persevering artist, Mr. Thomas Hornor, pass the whole summer of 1821, in taking a panoramic view of this vast metropolis and its environs, which is now publicly exhibited in an edifice erected for the purpose, in the Regent's Park.

When the visitor has reached the bull's eye chamber, it will not cost him much additional exertion of courage to mount into the ball which crowns the lantern. It is six feet two inches in diameter, and capacious enough to contain eight persons with ease. The weight of it is stated to be 5600 lbs. The cross, which is solid, weighs 3360 lbs.

In descending from this lofty perambulation, the visitor, when he reaches the whispering gallery, may return to the lower part of the church by a different staircase from that by which he ascended, called the geometrical staircase. It is, however, seldom used, and is chiefly resorted to by the curious in architectural matters, on account of the singularity and skillfulness of its construction. The stairs go round the concave

in a spiral direction; and the base is a circle inlaid with black and white marble, in the form of a star. The towers or steeples, which have been before described, as forming part of the western front, serve, one as the belfry, and the other as the clock tower. The great bell of St. Paul's, which is of some celebrity, never being tolled except at the deaths and funerals of members of the royal family, or of the bishops and lord mayors of London, when the sound of it is heard at a great distance, is stated to weigh four tons and a quarter. It has these words inscribed on it, Richard Phelps made me, 1716.

In the area before the west front of the cathedral there is a statue of queen Anne, by Bird, on a sculptured pedestal, representing Britannia, Hibernia, America, and France. Neither the statue nor the pedestal does much credit to the artist.

Church of Saint Faith.—In early times, there stood, near the east end of St. Paul's cathedral, a separate church belonging to St. Faith's parish; but it was taken down on the rebuilding of the cathedral, after the fire of 1086, in order to give greater room for the new fabric; and, in place of it, the parishioners of St. Faith's had assigned to them, that part of the crypt or vaults of St. Paul's situated immediately under the choir, which was formed into a distinct place of worship, and called *Ecclesia Sanctæ Fidei in Cryptis*. It became hence a common saying

This church needs no repair at all,
For Faith's defended by St. Paul.

In the reign of Edward VI. the parishioners of St. Faith's removed into another place of worship in the crypt, which had then been suppressed, called Jesus chapel; and the church of St. Faith was occupied by the Stationers' company, as a repository for their goods. After the great fire of London, the parish of St. Faith was united to that of St. Augustine; and, on the rebuilding of the cathedral, there was allotted to the parishioners of St. Faith a portion of the new crypt, for the purpose of interments, as also a large portion of the outer burial ground.

CHURCHES ERECTED PREVIOUSLY TO THE GREAT FIRE.

In London there are not above twenty churches which date their erection prior to the great conflagration of 1666. This fire destroyed eighty-nine churches, besides chapels, and threatened to annihilate every venerable edifice in the metropolis. One of the most ancient of those buildings which remain is the church of St. Peter ad Vincula, in the tower, already described. Several of the others are entitled to a brief notice.

St. John the Baptist.—This church is almost the only remains of the ancient palace of the Savoy, in the Strand, which was built in the year 1245. It does not appear that the chapel suffered by the riots of the Kentish rebels, already noticed, but a considerable part of the palace was demolished, and the whole was repaired in 1509. The roof of this church is very fine, being divided into pannels, on which numerous religious and heraldic devices are carved.

This church, which was very tastefully repaired in 1820, contains several ancient monuments of the Willoughby, Howard, and Compton families, as well as of other persons.

St. Dunstan's in the West.—No church in London was perhaps so well known as St. Dunstan's, in Fleet-street; not certainly on account of its external elegance, but for the equivocal celebrity it has acquired by the two wooden figures placed on a pediment in front, in 1671, representing savages, who indicated the hours and quarters by striking a bell with their clubs. As they were very visible in the street, 'they are,' says an historian, 'more admired by many of the populace on Sundays, than the most elegant preacher from the pulpit within.' Charity induces us to hope better, particularly as Dr. Donne, the celebrated Richard Baxter, and the pious Romaine, were preachers at St. Dunstan's. The old church of St. Dunstan was taken down, and replaced in 1832 by an elegant structure in the Gothic style, from a design by John Shaw.

St. Giles', Cripplegate, is one of the best Gothic buildings in London, and was erected in 1546, on the site of the ancient church, built by Alfune, the first master of Bartholomew Hospital in 1090, and burnt down in the year 1545. It is a light, airy, well-proportioned structure, which will always be attractive to the antiquary and the poet, on account of its being the place where Speed the historian, Fox the martyrologist, and Milton, were interred. Oliver Cromwell and his wife, Elizabeth Boucher, were married in this church.

St. Bartholomew the Great.—This church part of the ancient priory of St. Bartholomew, in Smithfield, owed its foundation to Raherus, 'a witty gentleman, and therefore in his time the king's minstrel,' about the year 1262. Matthew Paris relates a singular rencontre which took place in this priory, when Boniface archbishop of Canterbury, in a visitation, thought fit to go out of his diocese, and visit it. The canons, though willing to receive him as a guest, would not on this occasion acknowledge his authority; whereupon the bishop called the said canons 'English traitors,' and, after striking the sub-prior in the face 'the archbishop,' honest Mathew adds, 'with oaths not to be recited, rent in pieces the rich cape of the sub-prior, and trod it under his feet, and thrust him against a pillar of the chancel with such spiritual violence that he had almost killed him.' The archbishop was, in his turn, knocked down; but his men came to his assistance, and routed the canons, who 'ran bloody and mired and torn, to the bishop of London, to complain.' The church was rebuilt about the year 1410.

St. Bartholomew the Less.—This church, which is entered through Smithfield, appears to be of considerable antiquity, as there are monuments in it of as early a date as the year 1438. The sculpture in the interior, which is in the Saracenic Gothic style, is very antiquated.

St. Helen's, Bishopsgate, so called on account of its being dedicated to the mother of Constantine, was originally a priory of black nuns founded anterior to the reign of Henry III. The church, which is a light Gothic structure, with :

ower, built in 1669, is honored with the remains of Sir Julius Cæsar, Sir Thomas Gresham, Sir John Crosby, Hooke the astronomer, and other worthies. The parsonage was leased out by queen Elizabeth, in lieu of a pension, to captain Nicholas Oseley, who, while in Spain, gave the first intelligence to the English court of the fitting out of the Spanish armada.

St. Andrew Undershaft.—This church, which is situated in Leadenhall Street, is so called on account of a May-pole, or shaft, having formerly been raised here every year on the 1st of May, which was higher than the church-steeple, until Sir Stephen, a bigot of St. Catherine's church, preaching at St. Paul's Cross, called it an idol, when the inhabitants, over whose doors it had been suspended on iron hooks, returned home, and cut it to pieces. This church was rebuilt in the year 1525, at the expense of William Fitzwilliam, the founder of the noble house of Wentworth.

St. Olave, Hart Street, Crutched Friars, is a church which has nothing but its antiquity to recommend it. The first record of it is in 1319, since which time it has neither had external or internal grandeur to boast of; nor does it appear that a single individual of note sleeps within its walls.

Near the tower stood, till 1825, the *Church of St. Catharine's Square*, so called to distinguish it from St. Catharine Cree, already noticed. It formerly belonged to an hospital founded in 1148 by Matilda, consort to king Stephen. The church, which was collegiate, was a neat Gothic building, with several very handsome stalls; an elegant east window, which distributed a flood of light on all around; an octagonal pulpit, which represented, on its sides, the ancient building, and the several gates of the hospital; and an altar, which was the finest specimen of the Gothic style in England. The organ, which was erected in 1778, was fine toned and of great power. This church, after escaping the fangs of Henry VIII. and the Puritans, had nearly fallen a prey to the rioters of 1780, who, headed by a soldier of the name of Macdonald, and two women, were proceeding to demolish it, on the ground that it was built in the times of popery. But some of the members of the London Association arrived in time to save this venerable pile from destruction; and Macdonald and the women, who were afterwards arrested, were executed on Tower Hill. This church was, however, obliged to be taken down in the year 1825, to make room for the new dock, called St. Catharine's Dock.

St. Saviour's, Southwark.—This church, which was originally founded previous to the arrival of the Normans in this country, was successively a house of sisters, a college of priests, and a priory of canons regular, and was supported by a ferry across the river. The church, which was formerly, and is now sometimes, called St. Mary Overy, was rebuilt in the year 1400. John Gower, the poet, the friend of Chaucer, and author of the *Confessio Amantis*, was a liberal benefactor, and was interred within its ancient walls. When the priory had been surrendered to Henry VIII., or rather seized upon by that monarch, the inhabi-

tants of Southwark purchased it, with a charter which constituted the churchwardens a corporation. At a subsequent period this corporation appear to have manifested very little regard for their purchase, and to have actually let a part of it out for sixty years as a common bakehouse.

This church, which is very spacious, with three aisles and a cross aisle, like a cathedral, is of the ancient Gothic order; twenty-six pillars, in two rows, support the roof of the church; and the chancel, and the galleries in the walls of the choir, are adorned with pillars and arches, similar to Westminster Abbey. The tower, which is erected on four very strong pillars, with the spire, is 150 feet high, and contains twelve of the finest bells in Great Britain. It is memorable from its being the place whence Hollar took his views of London.

Gower is not the only poet who has been buried in this church, for here sleep, in one grave, Philip Massinger, and Fletcher. The celebrated cashier of the Bank, Abraham Newland, is also interred in an obscure corner of this church.

The *Church of St. Pancras*, which was built in the fourteenth century, is of small size and rude architecture; it consists of a nave and chancel, in which are several monuments; and no church or church-yard, in or near the metropolis, affords a last home to such a diversity of characters as are buried within its precincts. Jeremy Collier, the non-juror, and Father O'Leary, the amiable friar of the order of St. Francis; Pascal Paoli, the Corsican patriot (who has a monument in Westminster Abbey); Woollet, the engraver; Cavallo, the Neapolitan philosopher; and Chevalier D'Eon, the knight-errant of the last age, have all been buried in the church or church-yard, where a plain square monumental pillar, with a willow tree on each side, bears an inscription which records, that here also lie the remains of the philosophic Mary Wollstonecraft Godwin. The church-yard is remarkable for the great number of Roman Catholics interred in it; and the church was the last in England where mass was performed.

Allhallows, Barking.—This church, which escaped the fire, was built in 1651, at the corner of Seething Lane, Great Tower Street. It formerly belonged to the abbess and convent of Barking in Essex, whence its name is derived. It is a spacious church, and contains a mixture of Tuscan and modern Gothic architecture.

St. Ethelburga is a small church on the east side of Bishopsgate. It is supposed to have been erected in the year 1420; and a charity was founded here in 1436. It is a Gothic building, with a small spire; and, among other monuments, contains one in memory of a person of the name of Williams, who had attended on forty-two lord-mayors, and died in 1583.

St. James's, Duke's Place.—This church, which is very small, and built of brick, was erected in 1622 on the site of the priory of the Holy Trinity, founded by the empress Maud in 1108. As it was the richest priory in England, it was one of the first that was dissolved.

CHURCHES BUILT AFTER THE GREAT FIRE BY
SIR CHRISTOPHER WREN.

This great architect erected fifty new churches, between the years 1668 and 1718, a list of which, chronologically arranged, is subjoined.

St. Olave, Jewry, formerly called *St. Olave*, Upwell; situated in the Old Jewry, and erected after the fire of 1666.

St. Dunstan's in the East, *St. Dunstan's Hill*.—This church was only partially destroyed by the great fire. The body, which remained, has since been rebuilt, in 1820, under the direction of Mr. Laing, who was enabled to preserve the singularly beautiful tower and spire erected by Sir Christopher. The spire is raised on four Gothic arches, and presents a light and airy appearance.

St. Michael's, Wood Street.—So early as the year 1359 the church of *St. Michael's* was liberally endowed: and tradition reports, that the head of James IV. of Scotland was buried here, after the battle of Flodden field. The new church, which is of the Ionic order, was erected in 1669. The old turret has since been altered into a clumsy spire.

St. Stephen's, Walbrook.—This church is more celebrated on the continent than the cathedral of *St. Paul's* or Westminster Abbey.—Although there was a church in this parish so early as the year 1135, yet the site on which the present beautiful edifice is erected was not thus occupied until the year 1429. The first stone of the new church was laid in 1672, and in 1679 it was completed. The interior is allowed to be of the most beautiful and matchless architecture.

St. Mary, Aldermanbury, was erected on the site of an old church, which appears to have stood five centuries and a half, when the fire of London destroyed it. The infamous judge Jefferies was buried in this church.

St. Nicholas, Cole Abbey, Old Fish Street.—A plain stone building, with a square tower.

St. George, Botolph Lane.—A small neat church, of Grecian architecture: indeed, a large church is quite unnecessary, as the parish, according to the census of 1821, only contained thirty-three houses, two of which were uninhabited, and a population of 101 persons.

St. Bartholomew, Bartholomew Lane.—Rebuilt in 1670.

St. Stephen, Coleman Street.—A chapel belonging to the deans of *St. Paul's*; rebuilt in 1670.

St. Michael, Bassishaw, Basinghall Street.—An ancient rectory, which, in 1140, was in the presentation of the prior and canons of *St. Bartholomew's*. The old church, which was taken down in 1460, is said to have been very beautiful. Two centuries after it was rebuilt it was destroyed by the great fire, and succeeded by the present edifice.

St. Michael, Queenhithe.—Built in 1677.

St. Ann and *St. Agnes*, *St. Anne's Lane*.—A plain edifice with a square tower; built in 1685.

St. Mary-at-Hill, Lower Thames Street, was only partially destroyed by the great fire. It is surmounted by a plain square brick tower, built in 1670.

St. Christopher-le-Stock.—This church, which was rebuilt by Sir Christopher Wren, was taken down after the riots of 1780; and its site has since been occupied by the additional buildings to the bank of England.

St. Vedast, Foster Lane: dedicated to a bishop of Arras in 484; rebuilt in 1698.

St. Sepulchre's, Skinner Street.—It is not known when this church was first erected; but there are records of its existence in the middle of the thirteenth century; and it is probable that it is one of the oldest foundations in London. The church that was erected in 1440 was not entirely destroyed by the great fire, but it was almost entirely rebuilt in 1670.

St. Mary Woolnoth, Lombard Street.—Although this church is entered in the MS. of Sir Christopher Wren, yet it was built by his pupil, Nicholas Hawksmoor, probably from some designs by his master, particularly the interior. The Rev. John Newton, the friend of Cowper the poet, was rector of this parish.

St. Mildred's, Poultry, 1676.

St. Bennett Fink, Threadneedle Street, 1673.

St. Mary le Bow, Cheapside.—This church, which is supposed to have been erected in the reign of William I., was the scene of many interesting events. It was unroofed in 1090 by a tempest, and in 1271 a great part of the steeple fell down, when several persons were killed. Five years afterwards, when Fitz-Osbert, commonly called Long Beard, had raised an insurrection, he sought refuge in this church, and fortified it.

When the church had been destroyed, by the fire of 1666, Sir Christopher Wren, who had intended to raise two arches over the pavement, was compelled to erect the edifice to range with the street, when, in digging to the depth of eighteen feet, he found a Roman causeway four feet thick on which he laid the foundation. The principal ornament of this church is its steeple, which combines the five orders of architecture, and is considered as one of the chef-d'œuvres of this master. It is 225 feet high, and is surmounted with a gilt ball and dragon. The inside contains two Corinthian and two semi-pillars in length, against each of which are two pilasters; and it is from those that the arches between the nave and side aisles are turned. Their capitals are foliage, and the arches have cherubim on the key stones. They reach to the great cornice of the order continued round the church, and consequently the architecture and frieze are confined to the columns.

In 1818, a survey having been made of this church, the steeple was deemed unsafe, and it was determined that it should be taken down and rebuilt, which has since been done, and the church otherwise substantially repaired.

St. Michael's, Cornhill.—This church dates its origin beyond the year 1133, when it was presented to the abbot and convent of Evesham. The present church which is justly admired for its beautiful Gothic tower, and the admirable symmetry with which the various orders of architecture are combined, was erected in 1672. Fabian the alderman and historian has a monument in this church.

St. Magnus, London Bridge, 1676.

St. Edmund, Lombard Street, 1690.

St. Lawrence, Jewry.—Edward I. gave the patronage of this church to Baliol College, Oxford, which now possesses it. The church was rebuilt in 1677. It is a handsome building, and the interior has lately been rendered very elegant. A monument of archbishop Tillotson adorns this church.

St. Bride's, Bride Lane, Fleet Street, is another of those churches on which Sir Christopher Wren bestowed the greatest care. The church is a plain but neat structure; but it is in the lofty spire that the taste and skill of the architect are displayed. This spire was much injured by lightning on the 18th of June, 1764, when several large stones were forced from their places, one of which fell through the roof into the north gallery, and another was thrown into a house in Bride Lane. It was, however, soon repaired, though at an expense of £3000. This spire was again struck by lightning in 1805, and, in repairing it, the steeple was somewhat lowered. In 1822—3 this church, which the parishioners guard with just pride, was substantially repaired, and a rich window of stained glass added. Since this period advantage has been taken of a fire to throw open the view of this church from Fleet Street. Among the eminent persons buried, are Samuel Richardson, the author of *Pamela*; Sir Richard Baker, the author of the *Chronicle of the Kings of England*; Pope's *Corinna*, Mrs. Elizabeth Thomas; and Wynken de Worde, the famous printer.

St. Dionis, *Buck Church*, Lime Street, Fenchurch Street, rebuilt 1674-84.

St. James, *Garlick Hill*, rebuilt in 1683.

St. Peter's, Cornhill.—This church is of very ancient foundation, and very richly endowed. The present plain edifice was rebuilt immediately after the great fire. There is a plain monument in this church to the memory of seven children, the whole offspring of James and Mary Woodnason, who were burnt to death in a house in Leadenhall Street, in 1782.

St. Bennet, Paul's Wharf, built in 1181, and rebuilt in 1682. Inigo Jones is said to have been buried in this church, but there is no record of the circumstance.

St. Martin, Ludgate, 1684.

Allhallows the Great, Thames Street, 1683.

St. Swithin's, Cannon Street.—A small but elegant church, built in 1680, on the ruins of one of very ancient foundation. This church is memorable from the celebrated 'London Stone' being placed in front of it.

Christchurch, Newgate Street.—Previous to the dissolution of the monasteries, this was the church of Gray Friars, and one of the most superb conventual houses in the metropolis. It was built in the beginning of the fourteenth century, and was consecrated in 1325. The ancient church, which was burnt down in the fire of London, was of large dimensions, being 300 feet long, eighty-nine broad, and sixty-four feet high. The only part that has been rebuilt is the choir, to which has been added a tower, not remarkable for its exterior grandeur. It is an elegant and commodious church, which is

much frequented on account of the scholars of Christ's Hospital regularly attending divine service here. Weever, in his *Funeral Monuments*, relates that the old church was honored with the sepulture of four queens, nineteen of the nobility, and thirty-five knights.

Allhallows, Bread Street, 1684.

St. Austin's, or *St. Augustine's*, Watling Street, 1695.

St. Anthony's, Budge Row, built by Cartwright, from designs by Wren, 1682.

St. Mildred's, Bread Street, 1683.

St. Bennet, Gracechurch Street, of which there are records as early as the year 1190, was rebuilt in 1685.

St. Mary, Abchurch Lane, 1686.

St. Mary Magdalen, Old Fish Street, 1685.

St. Matthew, Friday Street, rebuilt 1669. Dr. Lewis Bayly, author of the *Practice of Piety*, and afterwards bishop of Bangor, was rector of this church in 1647.

St. Clement's, East Cheap, 1686.

St. Alban's, Wood Street, was originally founded by Athelstan, the Saxon king, who is said to have resided in a house adjoining, and whose name, somewhat corrupted and abridged, is preserved in Addle Street, formerly called King Adel Street. This church was rebuilt in 1631, destroyed by fire in 1666, and the present edifice, of the Gothic order, erected in 1685. It contains a richly ornamented altar piece, and a pulpit finely carved.

St. Margaret Pattens, Rood Lane, rebuilt in 1687. Some carvings in the altar piece of this church are by the celebrated Grinlin Gibbons.

St. Michael's, Crooked Lane.—This church, which was rebuilt in 1688-98, stands in Miles Lane. Sir William Walworth, who killed Wat Tyler, was buried in this church, to which Walter Warden bequeathed the Boar's Head, East Cheap; the identical house in which Falstaff kept his revels, as recorded by Shakspeare.

St. Margaret, Lothbury, an ancient foundation, rebuilt in 1690. It is a plain but neat church, with a handsome exterior, and a font beautifully ornamented with several historical subjects from the Old and New Testaments.

St. Mary Somerset, Upper Thames Street, first erected about the year 1335, and rebuilt in 1695.

Allhallows, Lombard Street.—A church was standing on this site so early as the year 1053; the present edifice was built in 1694.

St. Andrew's Wardrobe, more frequently called *St. Anne's*, Blackfriars, built in 1692. There is a fine monument to the memory of the Rev. W. Romaine in this church, where he preached for many years. It is allowed to be one of Bacon's best performances.

St. Michael Paternoster Royal, College Hill.—A college was founded here by the celebrated Sir Richard Whittington, which has since been converted into alms-houses, for thirteen poor men. A church was standing here so early as the year 1285. It was rebuilt by Sir Richard, who was interred here, and had a splendid monument, which was violated by the sacrilegious cupidity of a priest, named Mountain, who, disappointed of finding money in the tomb,

carried away the leaden coffin in which the body was enclosed.

QUEEN ANNE'S CHURCHES.—A few of these are entitled to notice, which must, however, be brief, although they embrace some of the most interesting specimens of ecclesiastical architecture, from the time of the fire to the commencement of the nineteenth century.

St. Martin's church, *St. Martin's Lane*, built by James Gibbs, between the year 1721 and 1726, is a beautiful edifice, and is now seen to great advantage by the removal of the closely crowded buildings surrounding it, and formation of Trafalgar-square. The west entrance has a very noble portico of Corinthian columns, the entrance to which is by an ascent of a long flight of steps. This church unites the light and picturesque beauty of the modern temple with the sober grandeur and solidity of Grecian architecture, and the spire is light and elegant. On the 1st of June, 1727, Mr. Volante, an Italian, descended head foremost by a rope, with his legs and arms extended, from the top of the steeple of *St. Martin's church*, over the houses in *St. Martin's Lane*, to the farthest side of the Mews, a distance of about 300 yards in half a minute. The crowd was immense, and the young princesses with several of the nobility were in the mews.

St. Paul's, *Covent Garden*, was erected by Inigo Jones, at the expense of the earl of Bedford, who, in giving his directions, said, 'a barn would do.' 'Then,' said Jones, 'you shall have the most magnificent barn in England.' On the 17th of September, 1795, this church was burnt down, but it was rebuilt according to the plans of Jones. It has a noble massy portico, of the Tuscan order, and the interior boasts of great neatness and simplicity. Butler, the admired author of *Hudibras*, Dr. Wolcot, and a continual succession of the children of Thespis, have been buried in the church-yard.

St. Giles's in the Fields.—This church is built on the site of a hospital, founded by Matilda, wife of Henry I. The present building was erected in 1730, the former edifice having become so ruinous as to render it necessary that the whole should be taken down. Over the north-west gate, leading to the church-yard, there is a representation of the Resurrection finely sculptured, which belonged to the old church. Andrew Marvell, the Yorkshire patriot, Sir Roger L'Estrange, and Richard Pendrell, the preserver of Charles II., are buried in this church or church-yard.

St. George's, *Bloomsbury.*—This church was built by Hawksmoor, the pupil of Sir Christopher Wren, and so closely did he calculate the expense that he only exceeded the estimate by £3. It is a singular, but by no means harmonious, compound of the Tuscan and Corinthian orders, with a good portico in the front. The steeple, which is pyramidal, is surmounted by a statue of George I., a circumstance that has been rather happily alluded to, in an epigram which states, that the pope only made Henry VIII. head of the church, but that king George's good people made him head of the steeple.

St. Mary le Strand.—This church does credit

to the taste and skill of Gibbs, who had just returned from Italy when he was called upon to erect it. Though somewhat thwarted in his original design, and urged by the commissioners for building the fifty new churches to spare no pains in beautifying it, whence he has been lavish of ornament, yet it is a superb edifice. On the proclamation of peace, in 1802, a serious accident occurred at this church, when one of the stone urns, which ornament the railing round the roof, fell and killed three persons, wounding several others.

NEW CHURCHES.—Under the head of new churches we include such as have been erected since the commencement of the present century, and these are sufficiently numerous to have given a character to the architecture of the age, did they not 'have no character at all.'

Within little more than a century and a half three great occasions have occurred to the respective architects of the times—the rebuilding of London after the fire of 1666, when England had an architect worthy of so vast a field—the building of fifty churches in the reign of queen Anne; and the numerous and extensive buildings in the metropolis during the last twenty years.

In the year 1818 a commission was appointed by royal patent, pursuant to a previous act of parliament for building, and promoting the building, of additional churches in populous parishes. The commissioners recommended the erection of several churches and chapels in London and its immediate neighbourhood, and no time was lost in carrying the proposed measure into effect. Previous to the parliamentary commission, a chapel of ease had been erected in the New Road, for the parish of Mary-la-bonne, which was afterwards enlarged and raised to the dignity of a parish church; a tower was substituted for a small cupola, a portico with six Corinthian columns added to its front which was extended, and several other alterations made, under the direction of Mr. Hardwicke the architect. The interior is fitted up with an upper and lower gallery, but it is decorated in a style much too gaudy for a place of worship. Mr. West, the historical painter, presented the church with a very fine picture of the Nativity, for an altar piece.

One of the first, and the largest, as well as the most expensive of the churches erected under the parliamentary commission, was that of *St. Pancras*, which was built at the cost of £70,000, by Mr. Inwood. The exterior is formed in imitation of the temple of Erectheus, at Athens, so far as regards its portico of six Ionic columns. The wings are on the model of the Pandrosium, which was attached to the temple of Erectheus, but they are too profusely ornamented. The eastern end is semicircular—though the original, whence the building purports to be copied, is square. The steeple, which is 165 feet high, is an avowed imitation of the temple of the Winds—with this difference, however, that the Athenian temple had no windows, and only four columns, while that of *St. Pancras* new church has fifteen. The interior of this church is tasteful and elegant; above the communion table are six

splendid antique Scagliola columns, with bases and capitals of white statuary marble. The windows are on the Grecian model, and the pulpit and reading desk are formed of the celebrated Fairlop oak.

If economy in the expense, correctness of design, and elegance of execution, are recommendations in a public building, the church of St. Paul, Shadwell, built in the year 1820, under the direction of Mr. John Walters, would stand at the head of modern edifices, since, although it only cost £14,000, yet the building is simply neat and elegantly chaste. The steeple is peculiarly beautiful; and in correctness of design, and in the simple harmony of its several parts, scarcely yields to the most admired object of the kind in the metropolis. Another church, which boasts some degree of neatness, has been erected at Hackney: it is of the Doric order, with a portico and cupola. The interior is fitted up with taste and simplicity, and the altar of Scagliola marble is elegant, though somewhat too profusely ornamented.

Several other churches have been completed, but they add so little credit to the architects and to the age, that the historian who passes them over will do no injury to the individuals, or to the national taste. It appears by the reports of the commissioners, laid before parliament in the years 1821, 1822, and 1823, that it was intended to build twenty-four new churches in the diocese of London, several of which were in progress.

DISSENTERS' CHAPELS.—In a country where every person may worship his Creator according to the dictates of his own conscience, chapels and meeting houses are necessarily numerous, and increase in proportion to the growth of the metropolis. In London there are six Jewish synagogues, the chief of which is in Duke's place—six meeting houses of the Quakers or Friends; in one of these, in White Hart Court, Gracechurch Street, which was burnt down in 1721, the great founder of the sect, George Fox, as well as the no less celebrated William Penn, preached. There are fifteen Roman Catholic chapels; one of these erected in Moorfields is remarkable for the elegance of its interior. Nineteen Foreign Protestant churches and chapels accommodate those who have embraced the reformed religion, and wish to attend divine worship in their respective languages. In one of these, the Dutch chapel in Austin Friars, several autograph letters of Calvin and other celebrated reformers are preserved.

The chapels of the Whitfieldian and Wesleyan methodists, and the various classes of protestant dissenters, exceed 160 in number, and are continually increasing. Many of these are remarkable for the popularity of the present, or the recollection of former eminent ministers. A building in Zoar Street, Borough, now used as a national school-room, is the place where John Bunyan preached, when in town; and such was his celebrity, that a few hours notice was sufficient to fill the chapel when he mounted the pulpit, even at seven o'clock in the dark mornings of winter. The chapel in Bury Street, St. Mary Axe, was the place where Dr.

Watts officiated; and New Court meeting, in Carey Street, among other distinguished pastors, has had the eccentric nonconformist Daniel Burgess, who preached with an hour glass by his side, and his no less celebrated or eccentric successor, Thomas Bradbury. The methodist chapel in the City Road was erected by John Wesley; and the Tabernacle, at a short distance from it, was built by George Whitfield. Here these celebrated and pious men promulgated their respective tenets, with the zeal of apostles, and the confidence of martyrs. Providence chapel Gray's Inn Lane, was built by the well-known William Huntington. This singular man, in a sermon which he preached soon after the destruction of Drury Lane and Covent Garden theatres in 1808 or 1809, congratulated his audience that 'two of the devil's temples had been burnt down;' when, a few weeks after, his own chapel fell a prey to the flames. He was soon, however, enabled by subscription to build a much larger edifice in Gray's Inn Lane. Simplicity and neatness are the general characteristics of the dissenting chapels.

We now come to the chief specimens of civil and municipal architecture, and here the *Mansion House*, as the abode of supreme city authority, takes the lead. It was not until July 1734 that the common council came to the resolution of appropriating the fines, paid into the chamber for not serving the office of sheriff, to the purpose of erecting a suitable mansion house, for the special use of the lord mayor for the time being. At this period there was not less than £18,000 in the chamberlain's hands, which had been derived in this easy way; and it was ordered, that this sum should in the mean time be invested in the three per cent. annuities, and that the growing interest thereon should be added to the capital every year, till the money was required for the proposed building. Previously to this, his own mansion, or the hall of some of the large companies hired for the purpose, was the residence of his lordship.

The site fixed upon was that anciently occupied by the stocks market, a structure for which the city was indebted to the liberality of Henry de Walleis, who was lord mayor from 1281 to 1285. It had been selected as a market place, because of its being in the midst of the city; and was now on the same account thought the best site that could be chosen for the residence of the chief magistrate. Although the corner stone was laid on the 25th of October, 1739, the building was not completed till the year 1753, in the mayoralty of Sir Crisp Gascoyne, who was the first chief magistrate that made it his residence. This delay was principally occasioned by its being found necessary to raise the whole structure upon piles. The total expense of the erection, including the purchase money of the old buildings, was £42,638 18s. 8d.

The mansion house, built from a design by Mr. George Dance, is a spacious and stately edifice, of rather heavy aspect. A bold flight of steps leads to a fine portico in front, composed of Corinthian columns, which spring lightly from a massy rustic basement, and are surmounted by a pediment; the tympanum of which exhibits a

piece of sculpture in alto relievo, by Taylor, emblematic of the dignity and opulence of the city of London. The general body of the building presents two tiers of lofty windows, and over these an attic story surmounted by a balustrade; the cornices are rich and deep, and supported by Corinthian pilasters. Were nothing more presented to the eye than the parts we have now described, the edifice, though lowly situated and too closely surrounded with buildings, could not fail to be pronounced elegant and complete; but, viewing it from the front, we behold, heaped as it were on the roof, and stretching crossways along the front, an ark-like pile of building, which throws an air of clumsy incongruity over the whole. Originally, there was a corresponding erection or hump towards the back of the building, but it was taken down a few years ago. Its companion cannot follow it too soon.

The interior is laid out with taste and judgment. Entering by the great door, you pass through a spacious saloon into what is called the Egyptian hall (for what reason, however, it would require Egyptian cunning to divine, for there is nothing of that character about it), a magnificent banquetting room, about ninety feet long from east to west (occupying the entire width of the house), and sixty broad, with a lofty concave roof displayed into compartments and richly ornamented. At the sides of the saloon there are also a justice room, a sword bearer's room, and a very handsome room called Wilkes's parlour. The area above the roof of the Egyptian hall being left open, the apartments of the upper stories form a surrounding quadrangle, with galleries of communication. The principal of these apartments are the hall room, which is about the same length as the Egyptian hall, but considerably narrower; a withdrawing room, and chief bed room provided with a splendid state bed.

The *Guildhall*, or common hall of the corporation, is situated at the upper end of King Street, Cheapside.

In 1411, during the mayoralty of Sir Thomas Knolles, the foundation of this edifice was laid; but only the great hall was at that time completed. Other parts of the building were added at subsequent periods of the fifteenth and sixteenth centuries, as the liberality of companies or individuals induced them to advance the means. At the great fire of 1666 the whole of the interior and outer offices were destroyed; but the walls were of such remarkable solidity, that they survived the fury of the raging element. The renovation of the interior was completed within three years after the fire, and at an expense of not more than £3000. It underwent a considerable repair about the beginning of the eighteenth century; again in 1780, when it received its present façade, and lastly in 1814.

The ancient front of the building appears, from the accounts and drawings of it, to have been in a style of considerable richness and grandeur. Some traces of its style may yet be seen in the interior of the present porch, the only part that has been preserved in its ancient state. The old front was ornamented by some remarkable fine statues. Engravings of some of them

may be consulted in Carter's *Ancient Sculpture and Painting*.

The present façade exhibits a tasteless jumble of the pointed, Grecian, and Oriental styles of architecture; parts multiplied to infinitude, and combined without the least relationship. On a pannel over the porch are the arms of the city (as represented in our first page), with the motto beneath them, *Domine Dirige Nos*, as suitable an inscription for a place of popular deliberation as could have been well selected.

The porch conducts us into what is called the great hall. It is 154 feet in length, and fifty-two in breadth; two magnificent windows of painted glass, at the east and west ends, diffuse over the whole a strong but mellowed light; and on each side are clusters of tall columns with gorgeous capitals, surmounted by a corresponding range of double piers, supporting a roof fifty-five feet high. From 6000 to 7000 persons may be contained within this hall, and on some important occasions the numbers we have seen assembled in it could not be less. The floor is of stone, furnished originally by the executors of the celebrated Whittington. The roof is supposed, with great probability, to have consisted, previously to the fire, of open-worked timber, similar to the roof of Westminster hall; it is now flat, and divided into large pannels.

At the east end of the hall there is an enclosed platform several feet higher than the pavement, and surrounded with a pannelled wainscoting, which is set apart for the accommodation of the lord mayor, aldermen, sheriffs, and other principal members of the corporation, at the meetings of the livery, and serves as a hustings at all elections. The more the great window over this platform is examined, the more it will be found deserving of admiration. Its divisions and subdivisions are all in the best harmony; their ornamental garniture light and elegant. In the compartments of painted glass there are well executed representations of the royal arms and supporters, and the stars and jewels of the Orders of the Garter, Bath, Thistle and St. Patrick.

Passing down the hall, the attention is attracted to a number of statues and pictures which occupy the spaces between the clusters of columns on each side, and call many interesting and appropriate recollections to the mind.

The first is a monument to the memory of the celebrated Beckford, who was lord mayor in 1763, and 1770. This magistrate is represented in the erect attitude in which he addressed to the king his celebrated reply, now known to have been written by Mr. Horne Tooke.

In another compartment, on the same side of the hall, is a still more splendid monument, to the memory of the earl of Chatham: executed by Bacon, who was paid the very handsome sum of 3000 guineas for his labor.

The sculptor has shown a remarkable degree of judgment in presenting us with a monumental groupe, which contradicts, as far as it possibly can, the notions of political economy conveyed by the inscription. The illustrious senator is exhibited in a Roman costume, standing upon a rock; his left hand rests on the helm of state; his right is energetically placed on the shoulder

of Commerce, who is presented to his protection by a female, whose mural crown bespeaks her the representative of the city of London; Britannia, reposing on her lion, occupies the foreground, and near her are four infants, emblematic of the four quarters of the world, pouring into her lap the cornucopia of Plenty. No demons, nor furies, nor dogs of war, figure here; four infants denote, as truly as expressively, that it is by peace and amity among all the nations of the earth that the horn of plenty is most certain of pouring its treasures into the lap of England.

Opposite to lord Chatham's monument, on the other side of the hall, is one to the memory of his son William Pitt, by Bubb; the sculpture not so good, the inscription better. The attitude of Mr. Pitt is appropriately oratorical; but, viewed with relation to the surrounding objects, it is an abstract conception, not well harmonized. From the turn given to the head, the face of the son seems as if purposely averted from that of his sire, which frowns on him from the opposite side in all its characteristic sternness.

At the lower end of the hall, on the north side, there is a monumental trophy to the immortal Nelson:—a huge heap of allegory, with a small profile of the great hero in the middle; only rescued from contempt by the admirable inscription from the pen of Richard Brinsley Sheridan.

We come now to the statues of those two high and renowned personages, Gog and Magog, which are situated at the foot of the hall, at the sides of the great western window. Each measures above fourteen feet high; and, being elevated on an octagon stone column, presents a right gigantic appearance. Which is Gog and which Magog, antiquarians have not yet been able to determine, though many and indefatigable their researches into this curious matter have been. The points of similarity between them, however, are so numerous, that we presume no great injustice can be done to either, should he chance to be called by his brother's name. Both are very huge and mishapen; have their brows encircled with wreaths of laurel, and their feet bound in sandals; they have long flowing beards, and still longer flowing sashes; both have been alike indebted to the bedauber of pink and blue, and green and yellow; each has a spear or pole in his hand, and a sword by his side; nor could any thing be more kin-like than the pensive dignity with which they look down on the emmet gazers beneath them. Who these worthies were, and why statues of them should have been placed in the Guildhall of the corporation of London, are two points about which the learned have long been divided in opinion. The author of a curious little work in 2 vols. 64mo., entitled, *The Gigantic History of the two famous Giants in Guildhall, London, 1741* (third edition), following the most respected authorities, assures us, that one represents Corinæus, a giant of Trojan descent, who came over with Brutus, the great grandson of Eneas, and won this country from the hands of

trance into London, these giants figured conspicuously in the pageant exhibited on the occasion at London Bridge; and they have occasionally travelled before or behind a royal or civic dignity since. Mr. Hone, whose researches have thrown much light on the history of these ancient relics, assures us, from personal examination, that 'they are made of wood, and hollow within, but too substantially built for the purpose of being [often] either carried or drawn, or any way exhibited in a pageant.' The construction of them he has also pretty clearly traced to the year 1707, and to a train-band captain of the city, of the name of Saunders, who received £70 for the pair.

In 1706 queen Anne made a present to the city, to be put up in this hall, of twenty-six standards, sixty-three colors, and a kettle-drum, all trophies of the memorable victory of Ramillies: but these have all disappeared. 'Had any other than a cobweb sweeper decided their fate,' says a spirited writer, 'not one of them would have been removed while a single tatter remained.'

Opposite to the porch of this hall there is a flight of steps which leads to a number of separate chambers, appropriated to the lord mayor and aldermen, the common council, the courts of the lord mayor and common pleas, the court of king's bench, and the chamberlain. The common council court is well worthy of a particular visit.

Somerset House, in the Strand, is the most spacious and the most elegant building in the metropolis, appropriated to public offices. It occupies the site of an extensive palace, which was erected about the year 1549, by Edward Seymour, duke of Somerset, who despoiled several churches and chapels in order to furnish materials for the structure.

This palace was occasionally occupied by queen Elizabeth, Anne of Denmark queen of James I., the consort of Charles II., and several queens dowager; and it has also sometimes been appropriated as a residence for foreign ambassadors. It appears to have been splendidly fitted up and furnished, for the period, and even when the building was taken down, about half a century ago, many vestiges of a royal residence were found. The original palace had received considerable additions by Inigo Jones, but even these were compelled to give way to modern improvement, when, in 1774, it was determined to erect a large suite of government offices on this spot. Sir William Chambers was selected as the architect, and although the economical spirit of the government, rather than the want of money, when it was undertaken, prevented him from completing his design, yet the building is such as to do credit to himself, and to the age in which he lived. It consists of a spacious quadrangle; the south front, on the banks of the river, has a very fine terrace, raised fifty feet above the bed of the river, and fifty feet broad, on arches of massive rustic work; the centre arch, or water-gate, is ornamented with a colossal mask of the Thames in alto relievo. The whole building is nearly 800 feet long, and 340 feet wide; the quadrangular court is 340 feet long, and 210 feet wide. The north and south fronts of the

Those mightie people born of giants' brood,
That did possess this ocean-bounded land;
and the other Gogmagog, the last of the British giants. When Philip and Mary made their ca-

quadrangle are formed by massive buildings of rustic work. The centre of the south side is ornamented with an arcade of four columns, with two pilasters on each side; on the columns rests a pediment, in the tympanum of which is a basso relievo, representing the arms of the royal navy, supported by a sea nymph. On the corners of the pediments are military trophies, and above the columns are very elegant vases. The east and west are nearly similar, but not so profusely ornamented. The front in the Strand is only 135 feet long. It consists of a rustic basement, formed of nine arches, three of which in the centre, are open, and form the entrance into the quadrangle. The three arches on each side of the entrance are filled with windows of the Doric order, and adorned with pilasters, pediments, and entablatures. On the key-stones of the arches, Ocean, and eight of his principal tributary streams, are exhibited in emblematic masks, in alto relievo. The basement is surmounted by ten lofty Corinthian columns (comprising two floors) on pedestals, with regular entablatures; the lower windows are surrounded with plain architraves, but the upper ones have a balustrade in front, and are ornamented with Ionic pillars, pediments, and entablatures. The three central windows have large tablets, covering part of the architrave and frieze, on which, in basso relievo, are medallions of their late majesties, as well as of their son, our present sovereign. The attic extends over three intercolumniations, and is divided into three parts by four colossal statues, placed over the columns of the order, emblematic of Justice, Truth, Valor, and Moderation. The whole is surmounted with a group, consisting of the arms of the British Empire, supported on one side by the genius of England, and on the other by Fame. The vestibule, which forms the only entrance, is closed at night by iron gates. It is decorated with columns of the Doric order. Over the side doors in the vestibule, leading to the Royal Academy and the Society of Antiquaries, are two busts, Ly Walton: that over the academy entrance represents Michael Angelo Buonarrotti, and the other is a bust of Sir Isaac Newton.

The principal public office in Somerset House is that of the receiver-general for stamps, one of the least oppressive and most prolific sources of revenue, yielding upwards of £6,000,000 annually. Here also are the tax and navy offices, the offices for the lottery, the duchy of Cornwall, the privy seal, the surveyor of crown lands, the victualling office, the signet office, and several others, in which several hundreds of clerks are employed.

We now conduct the reader to the *Royal Exchange*.—The place where the merchants of London commonly met for the transaction of business, for some centuries, was in Lombard Street, in which the Lombard Jews, from whom the street derives its name, and who were originally the bankers of all Europe, resided. Here too they probably kept their benches or banks.

At length, in 1534, Sir Richard Gresham (for Pennant is more than partial in giving the honor of the suggestion to his countryman, Clough), who was agent for Henry VIII., at Antwerp, and

had been much struck with the advantages attending the bourse or exchange of that place, prevailed with his royal master to send a letter to the mayor and commonalty of London, recommending to them to erect a similar building on part of their manor of Leadenhall. The court of common council, however, were of opinion that such a removal of the seat of business would be impracticable, and the scheme was therefore dropped.

Sir Richard was succeeded in the Antwerp agency, and in his public spirit, by his son, Sir Thomas Gresham, who, in 1564, proposed to the corporation, that, if they would procure a central and commodious site for an exchange, he would himself be at the cost of its erection. The corporation met the proposal in a spirit of equal liberality, and immediately purchased eighty houses, forming two little alleys leading from Cornhill into Threadneedle Street, which they pulled down, and then assigned the space on which they stood to Sir Thomas, for the erection of his proposed exchange.

On the 7th of June, 1566, the foundation of this edifice was laid, and with such activity did Sir Thomas proceed, that it was wholly completed before the November of the following year.

About two years after the building had been opened queen Elizabeth signified her intention of paying it a visit; but so many of the shops still remained unoccupied, that Sir Thomas found it necessary, two days before the promised visit, to go round among the shop-keepers, and beseech them 'to furnish and adorn with wares and wax lights as many shoppes as they either could or would, and they should have all those so furnished rent free for that year.'—Stowe. Her majesty was so much pleased at the appearance of the edifice, that she commanded that instead of the foreign name bourse, by which the citizens had begun to call it, it should be styled in plain English *The Royal Exchange*.

With those enlightened and humane views which the mercantile profession is known so often to inspire, Gresham now determined that whatever revenue might arise from the establishment should be devoted to the support of a free literary institution, to be denominated *Gresham College*, and to the sick and poor of the city. He executed a deed, by which he assigned for ever to the corporation of London and the Mercers' Company, in a joint trust, a dwelling-house which he possessed in Broad Street, for the accommodation of seven gratis lectures on divinity, astronomy, geometry, music, law, medicine, and rhetoric; and the whole produce of the Exchange buildings, for the payment, in the first place, of the salaries of the lecturers and other expenses of the college; and, secondly, of certain annual sums to different hospitals, prisons, and almshouses.

In the great fire of 1666 the *Royal Exchange* was among the many proud fabrics which that calamity reduced to ashes. 'What quick work,' says an eye-witness (the Rev. Samuel Rolle), can sin and fire make! How did that strong building vanish as of a sudden, as if it had been but an apparition! How quickly was it taken down, as if it had been but a slight tent, the

cords whereof are presently loosened, and the stakes removed. So fell that noble structure condemned by craft and covetousness, and overlaid with pride and prodigality.

When this lamentable disaster took place, the funds in the hands of Sir Thomas Gresham's trustees amounted to no more than £234 8s. 2d.; but, with a spirit beyond all praise, they resolved on making up from their own resources whatever might be the sum of money necessary for rebuilding the Exchange, in a style which might do honor to the age, and still farther honor to the name of Gresham. The king gave his cordial co-operation to the undertaking; and by an exertion of the royal authority, which deserves no place among the sins of the house of Stuart, so controlled the erection of new houses on the contiguous grounds, as to enable the trustees to give to the approaches of the new exchange a breadth and openness which the original one by no means possessed. His majesty, his brother the duke of York (afterwards James II.), and prince Rupert, went personally at different times and laid the foundation stones of the principal pillars of the building.

On the 28th of September, 1669, it was finally completed, and opened to the merchants, who had in the interval been accommodated with Gresham College as a place of meeting. The total cost of the building was £58,962, which the city corporation and the Mercers' Company defrayed equally between them. In the front of the building, immediately over the grand entrance, the following inscription commemorates the events we have been relating:—

HOC GRESHAMII PERISTYLIIUM,
GENTIIUM COMMERCII SACRUM,
FLAMMIS EXTINGUIT, 1666,
AUGUSTUS E CINERE RESURREXIT, 1669,
WILLM^o TURNERO, MILITE, PRÆTORE.

The plan of the new exchange is similar to that of the ancient one; and both took that of Antwerp for their model. An open area, 144 feet long by 117 broad, is enclosed by a quadrangle of lofty stone buildings, with a broad piazza inside and outside, except on the east and west sides of the exterior. The principal entrance is by an arched gateway at Cornhill, of magnificent proportions, and surmounted by a tower, 178 feet high, which has a clock in the middle story, and terminates in a cupola and globe with a gilt grasshopper (the crest of the Gresham family) as a vane. On the north or opposite side of the quadrangle there is another arched gateway of nearly equal dimensions. The interior area is neatly paved with small square Turkey stones, said to have been the gift of a Turkey merchant; and is divided, as well as the surrounding piazza, into what are called walks, to each of which the merchants of some particular nation, or branch of business, are in the habit of resorting, so that, though all the world may be said to meet on the exchange of London, you may always know where to find, at once, the person with whom you have business to transact.

In the centre of the area there is a good statue of Charles II. by Spiller, set up in place of a former one by Quellin of Antwerp; and in

niches of the surrounding buildings there are statues of most of our other monarchs from the time of Edward I. to George III. The statues of all the earlier sovereigns, as far as Charles II., are from the chisel of Gabriel Cibber; those of George I. and II. were done by Rysbrach, and that of George III. by Wilton. Some have been much injured by time; and whatever merit any of them may possess, as pieces of sculpture, it is sadly obscured by the sable shrouds in which our sea-coal atmosphere has enveloped them. In two niches under the piazza there are statues of the great founder of the building, Sir Thomas Gresham, and of Sir John Barnard, another eminent citizen, whose merit as a merchant, a magistrate, and a faithful representative of the city in parliament, his fellow citizens have thus sought to commemorate.

The interior of the exchange buildings, both above and below, was originally intended to be occupied as a bazaar, and it was so for a considerable period. The piazzas, both on the inside and outside, were lined with shops, and so also was the upper gallery. 'Robin Conscience,' in his progress through court, city, and country, 1683, tells us that after visiting the merchants on the area, where he got much abused for intruding himself, he

Did walk upstairs, where on a row,
Brave shops of ware did make a show,
Most sumptuous.

The whole of the shops have now, however, been entirely removed, except those of the exterior basement of the quadrangle. The upper part of the buildings, to which there is access by two spacious flights of steps under the north and south fronts, are occupied by different public companies, such as Lloyd's, the Royal Exchange Assurance, Merchant Seamen's, &c., and by private merchants and underwriters of respectability. The architecture of the exchange is of a mixed character; it is chiefly of the Corinthian order, and therefore not without considerable elegance; but the taste for ornament, which led to its adoption, has in many parts of the building run into profusion. The interior area is open to the public from eight in the morning till four in the afternoon, at which time precisely the gates are shut.

The Bank of England. For the origin of this all-important establishment, see our article *BANK*. The business of the bank of England was carried on at Grocers' Hall until the year 1734, although the increase of the establishment had long rendered larger premises desirable. At length, in 1732, it was determined to erect a new building of sufficient magnitude, and the site chosen was the house and garden of Sir John Houblon, the first governor of the company, in Threadneedle Street. The original building has since received so many additions, that it becomes more difficult to trace the architectural than the commercial growth of the establishment. The first edifice, which formed but a small portion of the vast fabric which now constitutes the bank of England, was raised under the direction, and according to the designs, of Mr. George Sampson, and was opened for business on the 1st of June, 1734.

This building was soon found insufficient for the increasing business of the company; and, some adjoining houses and ground having been obtained, wings were added under the direction of Sir Robert Taylor. In 1788 Mr. Soane succeeded as architect to the bank, and to him is the present building indebted for its principal ornaments, particularly the rotunda. He has recently added what may justly be considered the most splendid portion of this noble edifice. This consists of a new wing at the east end of the bank; the elevation forms a colonnade of six fluted Corinthian columns, which connect two pavilions; the columns do not form a portico, being barely insulated from the wall. The entablature, which is surmounted with a very fine parapet, has its frieze enriched with Vitruvian fret. The whole possesses much novelty, boldness, and elegant effect. The building altogether occupies an area of nearly four acres. The centre of the south front, erected by Sampson, is eighty feet long, and is of the Ionic order. The two wings added by Sir Robert Taylor were copied from a building by Bramante in the Belvidere gardens at Rome, and, although neat, did not harmonize with the centre. The north and west fronts have been erected by Mr. Soane, who in this, as well as in several other parts of the bank, has indulged in his favorite attachment to the Grecian architecture, which he has introduced in the purest style.

It is, however, in the interior of the bank that the skill of the architect is displayed to the greatest advantage. The rotunda, where the money-changers daily assemble to traffic in real or fictitious stock, is a fine octagonal room, fifty-seven feet in diameter, and covered by a dome; the whole building being of stone. It was erected in 1795, under the direction of Mr. Soane. The court-room, the pay-hall, the offices for the several kinds of stock, the hall, the apartments for the accommodation of the governor, the directors, and the cashiers, with the various offices requisite for the accommodation of 1100 clerks, who are now employed in the bank, are all admirably suited for the purposes for which they are constructed, and nothing can exceed the order and regularity with which the business is conducted.

Over the hall of the bank there is a curious clock, which, by communicating rods, indicates the march of time in sixteen distinct offices, where dial plates are placed; thus obviating the inconvenience which might arise in the transacting of business in the funds by the variation of different clocks. The affairs of the bank are managed by a governor, deputy-governor, and twenty-four directors, who are chosen annually.

The *Stock Exchange* is in Capel Court, once the residence of Sir William Capel, lord mayor in 1504. The first stone of this edifice was laid on the 18th of May, 1801, and the funds were raised by subscription: the plate which has been placed in the first stone bears an inscription, which after ages may consider as a questionable proof of national prosperity. Of national good faith it is certainly an indisputable memorial. It states that the public funded debt was then upwards of £500,000,000. There is nothing in the

building itself to excite particular attention, although it is conveniently and handsomely fitted up; but there is no place in the world where money transactions are carried on to such an extent: an assertion which will scarcely be doubted by those who consider the fluctuations which must occur in a funded property of £800,000,000 sterling.

In the stock exchange great pains are taken to exclude improper persons; and no one is allowed to transact business unless admitted a member by ballot. Four days a week the commissioners for the redemption of the national debt attend to purchase stock.

A singular custom, worthy only of the cupidity and intolerance of a barbarous age, is connected with this house. The number of Jew brokers admitted is limited to twelve, and these only on condition of purchasing the privilege by a liberal gratuity to the lord mayor for the time being. During the mayoralty of Wilkes, one of the Jew brokers was taken seriously ill, and his lordship is said to have calculated pretty openly on the advantage he would derive from filling up the expected vacancy. The son of the broker, meeting the lord mayor, reproached him with wishing his father's death. 'My dear fellow,' said Wilkes, with that sarcastic humor which was peculiar to him, 'you are completely in error, for I would rather all the Jew-brokers were dead than your father.'

Lloyd's Coffee-House is over the northern piazza of the royal exchange, and is the centre of British commerce—the point where it concentrates, and whence it diverges over the globe. A bank post-bill does not obtain a readier currency than an article of intelligence from Lloyd's, and to name this house as an authority is quite decisive with every person who knows the means of information it possesses, and its accuracy. It is also the great mart for maritime insurance.

The East India House is in Leadenhall Street, and here the directors hold their courts, and the chief business of the Company is transacted. It is a spacious building, a portion of which was built in 1726, but was not enlarged to its present dimensions until the year 1799. It cannot boast of much architectural neatness, although the front is crowded with ornaments. It consists of a portico, with six fluted Ionic columns, and two wings; the latter, which are extremely plain, are surmounted by a neat balustrade. The interior is fitted up in a manner which combines elegance and convenience: several of the rooms are very spacious. The museum is rich in oriental curiosities, as the library is in Asiatic literature: in the former are numerous trophies of British conquests in India. The library is frequently visited by oriental scholars from the continent, who are admitted by the directors with a liberality and a facility that shows a strong contrast to the unbending obstinacy with which public buildings are too frequently closed to the public in the metropolis.

The Post Office.—Posts appear to have been established in England so early as the reign of Richard III., but they must then have been an object of comparatively little importance; and the first mention we find of a post-master, in

England, is in the year 1581, when Sir Thomas Randolph, an able diplomatist, who had been employed in no less than eighteen distinct embassies, filled the office. On the union of Scotland with England, in 1710, a general post-office was established by act of parliament, which included not only Great Britain and Ireland, but our West Indian and American colonies. This extension increased the revenue of the post-office to £111,461.

The most remarkable event in the history of the post-office is the plan first suggested by Mr. Palmer, in 1784, of sending the letters by the coaches, instead of the old custom of transmitting them by post-boys on horseback. From this moment the prosperity of the post-office commenced; and the revenue which, after the progress of nearly two centuries, in 1783 only produced £146,400 annually, thirty years afterwards yielded a net revenue of nearly £1,700,000. Nor was it only in increasing the revenue that Mr. Palmer's plan was beneficial; for, to use the words of the parliamentary committee on the subject, 'at the same time that the revenue is augmented, answers are returned to letters in half the time, and with a degree of punctuality never experienced before: the expense is at a less rate per mile than upon the old plan; and, when the plan had been so far carried into effect that the mail-coaches had travelled above 40,000,000 of miles, 'not a single robbery had been committed, or a passenger insulted.'

The post-office consists of three branches; the general or inland, the foreign, and the two-penny post-offices. The general post-office is necessarily the most extensive and the most important, and some idea may be formed of the number of letters that pass through it, when it is known that the amount of postage on the letters delivered in London from this office sometimes exceeds £2500 in a single morning. Numerous as the letters are, such is the admirable arrangement that the whole business of the day is done in about six hours. On the day that a committee of the house of commons attended at the general post-office, to examine the details of the business, the number of letters amounted to 44,000, the whole of which were sorted and charged, by 105 persons, in the space of forty-five minutes. As auxiliaries to the general post-office, there are sixty receiving-houses, which are kept open until five o'clock every day.

The business of the foreign post-office, the inland letter-carrier's office for newspapers, and the ship letter-office in Abchurch Lane, is conducted in a similar manner, with a difference as to the days on which letters are made up, and the hours of attendance, as on foreign post days the office is open for receiving letters until twelve o'clock at night.

The two principal offices for the two-penny post are in St. Martin's-le-grand and Gerard Street; there are also upwards of 120 receiving-houses in various parts of the metropolis, which are continually adding to their number as new buildings are erected. The number of letters circulating in a population of 1,250,000 may readily be conceived to be immense; but there is one day in the year in which they are increased beyond any

thing that imagination could calculate—this is St. Valentine's-day; it appears by the official returns, that on the 14th of February, 1821, the number of letters which passed through the two-penny post-office in London exceeded the usual daily average by 200,000!

The late situation of the general post office in Lombard Street, though possessing the advantage of being in a central situation, was inconvenient for business so extensive; and more than ten years ago it was determined to erect a new office on a larger scale, and more worthy of this great city, on the site of St. Martin's-le-Grand. The first money raised was expended in purchasing the leases of the houses, and, for some time after they were removed, the ground remained unoccupied. The edifice is now completed; and, for purity of architectural design, may vie with the finest specimens in the Greek school.

The *Excise Office*, established in 1643, was formerly kept in the Old Jewry, and afterwards transferred to Broad Street, where a spacious and plain, but by no means inelegant building, was erected on the site of Gresham College and alms-houses in the year 1768. In this office the superior and local business of the excise is transacted by nine commissioners, with numerous officers and clerks under them. The gross amount of the excise in the year 1820 was £31,714,935 10s. 9d., of which a sum of £3,992,687 0s. 6½d. was paid in drawbacks, discount, and charges of management, leaving a net revenue to the country of £28,622,248 10s. 2½d.

The *Mint* is a very elegant building of modern date, which has been erected on Tower Hill, for the purpose of coining and issuing all monies, so necessary to the commercial intercourse of every civilised nation.

The business is conducted by a master and worker, who has a salary of £3000 a year, a deputy master and worker, comptrollers, assay masters, and a number of other officers, whose aggregate salaries, including that of the master, amount to upwards of £12,000 a year. The salaries of the officers, which are now liberal, were formerly very low, making every allowance for the times: in the reigns of Henry III., and Edward III., the warden's salary was two shillings a day; in the reign of Henry VI. it was only two shillings and sixpence, and the engraver had only £20 a year; now the warden has upward of £400, and the engraver £500 per annum.

The new mint on Tower Hill, designed by Mr. Smirke, and erected under his directions, is one of the most elegant structures in the eastern division of the metropolis. The building is of pure Grecian architecture, combining a modest grandeur with the convenience of being admirably suited to business. In the interior the arrangements are so complete as to exhibit one of the most remarkable proofs of the advanced state of the fine and mechanical arts to be met with in any part of the kingdom.

Corn Exchange.—The business of a corn broker, or factor, is one of modern growth and doubtful utility. Formerly the farmers of Kent and Essex used to send their grain up the river,

and attend a sort of market at Bear Quay; but, about the middle of the last century, when grain was cheap, the farmers often returned home without selling their grain. Those from Essex chiefly used the Bull Inn, Whitechapel; and the landlord, who was of an enterprising spirit, proposed that the samples, with the prices, should be left with him, in order that he might try to dispose of the grain in their absence. This man, whose name was Johnson, and who was originally the boots of the inn, soon got so much business in this way, that he opened an office at Bear Quay as a corn-factor, and amassed a fortune. The business of corn-factors afterwards increased so much, that they erected a market in Mark Lane, which is called the corn exchange. The building, with which two coffee-houses are connected, is of the Doric order; and the quadrangle, where the samples of grain are exhibited, is capacious. The brokers at first wished to render the corn exchange a private market; but, on an application to parliament, it was thrown open. Auxiliary to this market is a much neater though smaller structure, called the new Exchange for Corn and Seed.

The Coal Exchange.—Coals appear to have been first used in London about the year 1307; but the smoke was supposed to corrupt the air so much, that in 1373 the use of them was prohibited by a royal proclamation: the quantity now consumed is immense, although in the metropolis they are subject to an impost, from which nearly every other part of England is exempt. The first duty on coals was 1s. per chaldron, which was imposed, immediately after the great fire, in order to raise wharfs along the river. In 1670 an additional duty of 2s. per chaldron was laid on all coals entering the port of London, for the purpose of rebuilding churches, &c.; and those duties, though for a specific purpose and a limited period, have been increased until they amount to 9s. 4d. per chaldron. Legislative enactments have frequently been deemed necessary in order to regulate the coal trade, and others are still called for. In 1804 it was resolved to erect a regular market for vending coals, and premises in Thames Street were purchased for the purpose, where the present coal exchange, which contains a handsome front and a neat rotunda, was erected. Since the extensive application of steam-engines in factories, and the introduction of gas, the consumption of coals in London has been much increased. In 1801 the quantity imported into the port of London was 884,339 chaldrons; and in 1823 it was nearly double, being 1,437,951, the duty on which amounted to £670,717 2s. 8d.

Garramny's and the *Auction Mart* are other public commercial resorts of immense business, but of little architectural importance.

The Inns of Court are important adjuncts to the metropolis. Fortescue inclines to the opinion, that they were called so at first, not because the persons resident there followed the profession of the law, but simply from their being the inns, hospitals, or hotels, where young men of family and other persons attached to the court were wont to reside.

Among the very ancient inns, of which there is no longer any trace, one called Chester inn is

said to have been situated on the spot where Somerset House now stands; a second at Dowgate; a third in Paternoster Row; and a fourth somewhere still nearer St. Paul's cathedral, which in the days of its profanation was the great place of business for lawyers. Each practitioner had his own pillar in the cathedral, where he took his stand at stated hours of the day, with a pen and paper book, ready to receive the instructions of clients. So perfectly, indeed, was the practice recognised, that on the making of a sergeant, it was usual for the whole body of sergeants to walk in their robes to St. Paul's, to invest their new brother with his particular pillar of business.

The number of these inns of court appears in the reign of Henry III. to have been so much on the increase, that it was thought necessary to restrain them by proclamation. Some which now exist were however erected after this prohibition. The number remaining is thirteen, nine of which are within, and five without the liberties of the city, and all (we believe) extra parochial.

The inns were anciently of three classes; two of these might properly have been designated the outer and inner; the third bore the name of Serjeants' Inn. The outer were called Inns of Chancery, from their being places of elementary instruction, where young men were taught the nature of chancery writs, which were then considered as developing the first principles of law. Such were Clifford's, Thavie's, Barnard's, Staple's, Clement's, Lyon's, New Inn, and some other inns now extinct. In the reign of Henry VI. there were ten of these lesser inns, each of which contained not less than 100 students. When persons had made some progress at these inns, they were then admitted into the superior or inner courts, where they perfected their degrees. Of these courts there were four, namely, the Inner and Middle Temple, Gray's Inn, and Lincoln's Inn, which still retain the pre-eminence they originally possessed. At the period of which we have spoken none of these inns of court had less than 200 members.

The Serjeants' Inns, of which formerly there were three, were of a still higher order than any of the others, being occupied solely by the lawyers who had been advanced to the dignity of the coif, including the judges, who, though promoted to the bench, still style every serjeant their 'brother.' One of these, which was situated about the middle of Fleet Street, was held on a lease from the dean and chapter of York; and on the expiry of the lease it was not thought proper to renew it. The place, though now differently occupied, still retains the name. Another inn, for the use of serjeants only, was situated in Scroop's court, Holborn, near St. Andrew's church. The only Serjeants' Inn, at the present day, is situated at the foot of Chancery Lane.

College of Doctors of Law.—The doctors of the civil, canon, and maritime laws, practising in the ecclesiastical and admiralty courts, have a college of their own, situated in Knight Rider Street, usually called Doctors' Commons, from their communing together in a collegiate manner, as in the inns of court. At first the doctors resided in a mean house near Paternoster Row,

which is now a tavern, known by the name of the Queen's Arms. Afterwards Dr. Henry Harvey, dean of the arches, purchased an old stone structure in Knight Rider Street, held on lease by lord Mountjoy, from the dean and chapter of St. Paul's, and fitted it up for the accommodation of the fraternity. Here they resided till its destruction by the great fire; when they removed to Essex House, which they occupied till 1672, when the present commodious buildings were erected.

As yet, the members, though professionally associated together, were not legally incorporated; nor was it till 1768 that an act for this purpose was obtained.

The college has a handsome hall, where the different courts in which its members officiate hold their sittings. The doctors or advocates sit on the same bench with the judge; and each has a particular seat assigned to him on his admission, which he always keeps.

The principal ecclesiastical court is the *Court of Arches*, said to be so called from its having been anciently held in the crypt of Bow church, which was originally built upon the arches. The thirteen parishes in London, and laie peculiars of the archbishop of Canterbury thale under the immediate jurisdiction of the oing of this court, who is hence styled the *deci are coaches*. The *Prerogative Court* is guardian of the various rights of succession to property. It has a registry attached to it, in which all original wills are deposited: and grants letters of administration to executors and next of kin. The *Office of Faculties and Dispensations* empowers any one to do that which in law he could not otherwise do; as, for instance, to marry without the publication of banns, to succeed a father in an ecclesiastical benefice, &c. The *Court of Delegates* is the highest of all the ecclesiastical courts of the province of Canterbury. Appeals lie to it from any of the other courts, and the decisions are generally considered final. The king has it in his power, indeed, to grant a commission of review under the broad seal, but this is rarely exercised. The *Court of Admiralty* takes cognizance of all offences on the high seas, questions relating to seamen's wages, right of salvage, &c. It was erected in the reign of king Edward III. and was originally held in Southwark. When the causes before it relate to offences committed at sea, it does not hold its sittings here, but at the sessions house in the Old Bailey; and any barrister at common law may then plead before it. The doctors of law have an excellent library attached to their college.

The Rolls.—The master of the rolls is ex officio lord of a liberty of itself, exempt from the power of the sheriff of Middlesex, and of every other officer, except with leave of the master. Here he has a splendid house to reside in, from which he can pass into the court where he officiates, as from one room into another; and behind it there is a large garden, where, in the midst of a crowded city, he may enjoy something of the pleasures of rural retirement. Here also he has a chapel of his own, the minister of which is of his nomination.

The chapel is an ancient structure, of a mixed character, and is supposed to have been designed

by Inigo Jones. It contains several monuments to the memory of persons who have filled the office of master; one by Torregiano, in honor of Dr. Young, who died in 1616, is particularly admired.

In 1717 Sir Joseph Jekyll, on being appointed master, found the houses belonging to the liberty in so ruinous a condition, that he was induced to rebuild no less than thirty-nine of them at his own expense; although, by an act of parliament, the master is restrained from granting leases for a longer period than forty-one years. The cost of these erections was not less than £30,000.

The total amount of the rents of houses in the liberty of the rolls, as charged to the poor rates some years ago, was £7282.

We now turn to the *charitable erections* of this great city. *Institutions.*—In the metropolis there are thirty-nine principal religious societies formed for the purpose of disseminating religious instruction to every nation and to every people. Some idea of the extent of the pious benevolence of England—for, it is proper to acknowledge that the whole sum is not collected in London, though principally so—may be formed from the following statement of the receipts of the religious charities in the year 1822:—

	£	s.	d.
British and Foreign Bible society	97,062	11	9
Society for promoting Christian Knowledge	57,566	19	5
Church Missionary society	35,000	0	0
Wesleyan Missionary society	31,748	0	0
London Missionary society	31,266	1	11
Moravian Missionary society (in London)	2,691	8	3
Home Missionary society	4,311	1	9
Society for the Conversion of Jews	11,400	9	10
Religious Tract society	8,854	9	4
Church of England Tract society	636	8	8
Female Penitentiary society	3,219	4	0
Society for the Relief of Pious Clergymen	2,282	8	2
Prayer Book and Homily society	2,082	9	6
British and Foreign School society	2,053	16	11
Naval and Military Bible society	1,929	2	9
Sunday School Union society	1,746	19	2
Continental society	1,536	7	2
African Institution	1,134	2	1
Society for promoting Religious Knowledge among the Poor	825	15	7
Society for Encouragement of Female Servants	819	18	6
Merchant Seamen's Bible society	648	10	2
Sunday School society	540	4	6
Society for Building Churches and Chapels, total from commencement	61,913	3	10
Ditto, annual subscriptions	630	14	0
Hibernian society	8,984	13	6
Hibernian Bible society	4,343	0	11
Irish Religious Book and Tract society	3,750	7	7
Irish Evangelical society	2,275	2	3
Sunday School society for Ireland	1,883	17	0
Irish Baptist society	1,771	0	0
Irish Society of London	403	6	7
	£385,302	8	7

Nor does this sum, large as it is, include all the money collected for religious charities, as there are various other societies, which, like tributary streams, flow into the ocean of benevolence. In a preceding year some of the institutions produced more money than in the year 1822, particularly the Bible society, the receipts of which, in the year 1821, amounted to £103,802 17s. 1d.

There are twenty-four hospitals for the sick, the lame, for children, for the cure of particular complaints, as diseases of the eye, or the ear, &c.;—numerous alms-houses for the maintenance of the aged, and upwards of thirty dispensaries for the gratuitous supply of medicine and medical aid to the poor, 60,000 of whom are thus annually relieved. In justice to the medical profession it ought also to be said, that not only several apothecaries, but even physicians and surgeons of the highest rank, give advice gratuitously to the poor once or twice a week. Reserving for a distinct notice some of the most prominent of the London charities, it may be necessary to give a cursory view of the beneficial influence and effects of others.

Of all the institutions in London, there is not one more humane or more useful than the *Society for the Discharge and Relief of Persons imprisoned for Small Debts*, which was established in 1772, principally through the means of the unfortunate Dr. Dodd.—Within the first fifteen months after this society was formed, 986 prisoners were liberated through its means; and the number discharged and relieved in 1818, from various prisons in London and the country (for its benefits are not confined to the metropolis), was 1138 persons, who had 823 wives, and 2187 children. The sum with which so much good was achieved is comparatively trifling; the average expense of the liberation of each prisoner, including every incidental expenditure relating to the charity, being only £2 17s. 2½d.

The *Westminster Hospital*, or public infirmary, which was established in 1719, was the first institution of the kind in England, and may be considered as the parent of all the subscription hospitals in the kingdom. Since its formation it has afforded comfort and relief to more than 174,000 of the sick and afflicted poor.

The *City Dispensary*, in Grocers' Hall Court, Poultry, is an institution of the utmost usefulness. Since its establishment, in 1789, 138,302 patients have been admitted. Of these 136,442 have been cured or relieved, 393 discharged for irregularity, and only 1467 died: 50,346 persons have been attended at their own habitations, and several thousands relieved without the formality of a letter of recommendation. The number of persons who receive medical or surgical assistance from this institution, every year, is nearly 5000.

The *National Vaccine Establishment* is another institution of extensive utility; many diseases have their thousands of victims every year, but the small pox had its tens of thousands. What an alteration is there now, not only in the human countenance, but in the aggregate duration of human life, which has been increased more than two-years by vaccination alone! It appears by

the last report of the vaccine establishment, that, within the five years ending in 1823, 34,275 persons have been vaccinated in London; and the total number vaccinated in Great Britain during the same period was 327,521 persons.

The *Royal Humane Society* was instituted in 1774, for the recovery of persons apparently drowned or dead, by diffusing a knowledge of the best means to be resorted to in such cases, and by rewarding with honorary medals such individuals as have exerted themselves to save the life of a fellow creature. One of these medals, which may be compared to the most honorable reward the Romans could bestow—the corona civica,—was given to the emperor Alexander of Russia, who was instrumental in saving the life of a peasant, and who was more honored by this mark of distinction, than if 'stuck o'er with garters and hung round with strings.' The society has twenty receiving houses in the metropolis, where persons are in attendance with the necessary apparatus to be employed. Since the commencement of this establishment, it has been the means of saving the lives of 5500 persons, who were ^{which} ~~apparently~~ dead; and more than 21,000 persons, ^{by} ~~who~~ rewarded for their exertions in ^{judging} ~~of~~ the ^{of} ~~the~~ shipwreck.

The out similar to that of the Royal Humane Society, have been formed in various parts of Great Britain; and the example is already adopting in most of the nations of Europe.

The *Royal Universal Dispensary for Children*, which is open, in cases of danger, to a first application for relief without recommendation, was instituted in the year 1816; and since ~~that~~ ^{the} time 60,000 children have been attended, ~~only one~~ ⁱⁿ ~~in~~ ^{sixty} of whom died. Since this dispensary was instituted, the number of children in London, under ten years of age, that have died, is 5000 less than in the preceding seven years.

The *Royal Infirmary for Diseases of the Eye*, though an infant establishment, has preserved the sight of thousands. It appears from the report of this institution, in 1822, that since the opening of the charity in 1805, 32,400 poor persons have received the benefit of the charity: and of this number (which is upwards of 2000 annually) 30,250 have been discharged, cured, and relieved; and 888 deemed incurable. During the same period 1252 operations, for the removal of the cataract, had been performed, 1174 of which terminated successfully, although of this number of cases 122 persons had been born blind.

There are fourteen hospitals in London, expressly appropriated to females during a period, when, of all others, they most require assistance. Some of these are for attending married women, at their own habitations, gratuitously; others for affording them pecuniary relief, or the loan of linen, &c.: and a third class of hospitals is for admitting in-door patients. The City of London Lying-in Hospital, in the City Road, which is perhaps the largest of these establishments, was founded in 1750, and Dr. Sherlock was one of its earliest patrons. From this period, to the year 1809, 24 902 poor married women were

assisted, and 25,196 children born within the walls of the hospital. A singular instance of the advantage of having all the departments of a public institution filled with persons duly qualified for their office occurs in the history of this charity.

The *British Lying-in Hospital*, in Brownlow Street, was instituted in 1749, and a remarkable instance of the advancement of medical science is exhibited in the records of this charity. During the first ten years after its establishment one woman in forty-two died; and, in the fifth ten years, only one in 288. In the first ten years one child in every fifteen died, but in the fifth ten years the number of deaths was reduced to one in seventy-seven, and afterwards to one in ninety-two.

The *Strangers' Friend Society* was formed for the purpose of relieving the distressed. The principles on which this truly charitable institution is founded are the most benevolent and disinterested. Neither country nor religion is considered as an obstacle to its relief; and, in carrying on this work of mercy, 300 visitors are employed 'to enquire the wretched out,' whether living in garrets or cellars, and well do they discharge this painful and laborious duty, without any other reward than that which arises from the consciousness of doing good.

Such are a few of what are considered the minor benevolent institutions of the metropolis—to do justice to their history would require limits much more extensive than we can assign to them.

Alms-Houses.—Independent of the charitable institutions of the several corporate bodies of the city of London, they are the guardians or trustees of several other charities.

There are in London 110 different foundations of alms-houses, in which upwards of 1500 persons of both sexes are comfortably maintained, in a degree of comparative independence. The Drapers' Company, whose charitable donations are upwards of £4000 a year, have alms-houses which contain 113 persons, either founded by themselves, or by individuals who have appointed them guardians; and among the charities, the administration of which is vested in the Drapers' Company, is 'queen Elizabeth's College,' at Greenwich, which was founded for twenty-four persons, in 1576, by William Lambarde, the author of the *Perambulation of Kent*, and is said to be the first hospital which was founded by a protestant. In the parish registry of Greenwich, there is a singular instance of marriage and longevity connected with these alms-houses. It states, that on the 18th of November, 1685, John Cooper, alms-man, in queen Elizabeth's College, aged 108, was married to Margaret Thomas, of Charlton, aged eighty, by leave of the governors of the drapers.

Bridewell Hospital.—The recollection of Mendicity almost involuntarily associates itself with Bridewell, since the latter was one of the first institutions formed with a view to relieve and suppress it. The site on which this hospital is built was anciently occupied by a royal palace, which must have been built long anterior to the time of William the Conqueror, as during the

reign of that monarch it was so much dilapidated that he gave some of its materials towards the rebuilding of St. Paul's. Henry I. despoiled it for the same purpose; but the palace still remained, and was long a royal residence. Cardinal Wolsey, who built as well as occupied royal palaces, resided here in 1552; and, when the emperor Charles announced his intention of visiting England, Henry VIII., with a celerity unusual in those days, had it taken down and rebuilt for that sovereign's reception, in the course of six weeks. For some reason, which is not recorded, his imperial majesty did not reside in the palace, and it was appropriated to the officers of his suite.

Although historians relate that the palace was rebuilt in a magnificent manner, yet this seems doubtful, as in the succeeding reign bishop Ridley, in a letter to Sir William Cecil, secretary to Edward IV., describes it as a wide, large, empty house, 'that would wonderfully well serve to lodge Christ in, if he might find such good friends in the court to procure in his cause.' The pious bishop says, many lie in the streets 'both hungry, naked, and cold,' that the citizens were willing to refresh them, but they lacked lodging; and he adds, as a climax to the misery he paints, that 'in some one house, I dare say, they are fain to lodge three families under one roof!'

The king granted the petition, and the house from that time has been employed 'for the correction and punishment of idle vagrant people, and for setting them to work, that they might, in an honest way, take pains to get their own livelihood.' Bridewell is one of the royal hospitals which Edward VI. endowed with 700 marks of land, formerly belonging to the Savoy, which had been suppressed. It is at present used as a house of correction for the dissolute, as a refuge for the destitute, and as a manufactory for the industrious.

St. Bartholomew's Hospital.—Five hospitals in London are termed royal on account of their having been founded or endowed by English sovereigns; these are St. Bartholomew's, St. Thomas's, Bethlehem, Bridewell, and Christ's Hospital. St. Bartholomew's, in West Smithfield, may claim as a benevolent institution an antiquity of more than seven centuries, it having been originally founded in 1102, by Raherus, who is said to have been a minstrel to Henry I. and established a priory of black canons near it. The endowment which was for 'brethren and sisters, sick persons, and pregnant women,' was £305, and it received several additional bequests, which were given previous to the time of Henry VIII., who, while he suppressed the monastery, preserved the hospital, and gave 500 marks a year to it, on condition that the city should give an equal sum. The citizens repaired the ruinous houses the monarch had bequeathed, at an expense of £1000, and provided the means of receiving 100 persons into the hospital so early as the reign of Edward VI., who incorporated it. The expenses of the hospital at this period amounted to £795 a year; the king's endowment, after the repairs made by the city, produced the 500 marks,—a similar sum was

given by the corporation, and the deficit was raised by the citizens. No sooner did the funds admit of an increase of patients, than it was made so, that in the year 1660 the hospital maintained upwards of 300 sick or lame persons at an expense of £2000 a year. The hospital fortunately escaped the dreadful conflagration of 1660, although several houses constituting a portion of its revenues were destroyed, but they were almost immediately rebuilt by the citizens, and then became more productive than ever. Thus the hospital continued until the year 1730, when it was deemed necessary to rebuild the whole by a subscription raised for the purpose.

The building forms a quadrangle, with an inner court of considerable dimensions. The principal entrance in Smithfield, erected in 1702, is of the Doric order of architecture, and consists of a large arch, surmounted by a statue of its nominal founder, Henry VIII. The royal arms, and two figures representing sickness and lameness, also ornament the front. The interior of the hospital is spacious and well arranged. The hall, which is large, contains several paintings, particularly one, representing St. Bartholomew holding the knife by which he was flayed alive, a portrait of Henry VIII., and another of Dr. Ratcliff, who was a great benefactor to the hospital. The staircase is indebted to the gratuitous pencil of Hogarth, who has enriched it with a picture of the cripple at the pool of Bethesda, and another of the good Samaritan, as well as other paintings, in return for which he was elected a governor. St. Bartholomew's Hospital, which formerly had two auxiliary establishments, in Kingsland Road, and Kent Street, in Southwark, is open to accidents at all times, and there is considerable facility given to the admission of patients, who receive the best medical and surgical advice. The number of in-patients is about 5000, and that of out-patients nearly 6000 annually.

St. Thomas's Hospital, in Southwark, devoted to the same objects as that of St. Bartholomew, under the same government, that of the lord mayor and aldermen, or a select portion of them, owes its royal foundation to the same prince, and extends relief to the same extent; the number of poor admitted as in or out door patients in 1820 being 11,451.

This hospital owes its origin to two similar charities, founded in the early part of the thirteenth century—a hospital built in 1207, by the canons of the priory of St. Mary-over-Rhe, and an almonry or alms-house, erected by Richard Prior of Bermondsey, for the reception of indigent children, and necessitous proselytes. In the year 1538 it was surrendered to the crown; and in 1551, when the mayor and citizens purchased the manor of Southwark of Edward VI. for the sum of £647 2s. 1d., they repaired and enlarged the hospital, so as to render it capable of receiving 260 poor, sick, and helpless objects.

In 1693 it was deemed necessary to rebuild the hospital, which was done in three quadrangles by subscription. The benevolent Thomas Guy built three of the wards at his own expense, and Thomas Frederic, esq., one of the governors,

built three others. Another quadrangular court with several wards and offices, was added in 1732, which increased the number of wards to nineteen, containing nearly 500 beds. Sir Robert Clayton, who was lord mayor in 1680, was a great benefactor to this excellent charity.

Though not honored with the appellation of 'royal,' the foundation of *Guy's Hospital* was an act of more princely liberality than either of the preceding. It is one of the most munificent gifts that an individual ever presented to the public; and although it may be contended, that Guy (see that article), gave his money in public charity out of pique, yet the whole life of this man was such a scene of continued beneficence, that it is fair to presume he would, under any circumstances, have appropriated a considerable portion of his fortune to works of charity. It has been seen by his munificence to St. Thomas's Hospital, that he was an individual by no means of ordinary benevolence; nor was the hospital, which bears his name, an act of posthumous charity, but, on the contrary, erected during his life, at an expense of £18,793 16s. 1d., although he did not live to see it finished. The foundation was laid in 1722, and two years afterwards Mr. Guy died, having endowed the hospital with the vast sum of £219,499 0s. 4d.; he also left a perpetual annuity of £400 a year to Christ's Hospital, and £1000 for discharging such poor prisoners as could be released at an expense of £5, by which above 600 persons were set at liberty; nor was Guy unmindful of the claims of kindred, for he bequeathed annuities for life to them of £870, and legacies to the amount of £75,589. *Guy's Hospital*, which possesses no architectural claims to particular notice, consists of a centre and two wings, which includes thirteen wards. The number of in and out patients admitted annually, varies from between 4000 and 5000.

The governors of the hospital are incorporated, and, by an act passed in the year 1808, it is joined with the royal hospitals, the Foundling, the Universities, and Colleges of Eton, Winchester, and Westminster, in the clause of exemption from the tax on servants.

Bethlem Hospital was not originally in Moorfields, but was formed out of a priory on the site of the street in the ward of Bishopsgate, now called Old Bethlem, built by Simon Fitzmary, a sheriff of London, in the year 1247. Three centuries afterwards, Henry VIII. granted the lands and revenues of the priory to the corporation of London, for the reception and maintenance of lunatics. The number of these unfortunates increasing considerably, a more spacious building became requisite, when the corporation appropriated a plot of ground in Moorfields for the purpose, and a new building was erected in 1676 by subscription, at an expense of £17,000, to which two wings were added in 1733.

The hospital becoming ruinous, and its removal consequently desirable, in order to make the projected improvements in Moorfields, it was determined to erect a more magnificent building for the purpose, on the site of the Dog and Duck Tavern, in George's Fields. The building, which was begun in 1812, and com-

pleted within a short period, is a very magnificent structure, extending, the centre and wings included, to the length of 580 feet in front. The centre has an Ionic portico of six columns; and the building is surmounted by a neat dome. The hospital was designed by Mr. Lewis, and cost upwards of £95,000.

It appears from a return made by the physicians of this hospital to the governor, in January 1822, that the number of patients in the hospital was 346; of whom 210 were deemed curable; seventy-seven incurable, and fifty-nine criminals who were to be confined for life, among whom were Margaret Nicholson and Hadfield, the two individuals who attempted to assassinate his late majesty.

Bethlem Hospital does credit to the talents of the architect, and is an ornament to this part of the metropolis. The two celebrated statues of raving and melancholy madness, by Caius Ciber, which formerly stood on each side of the gates in the hospital in Moorfields, are now placed in the hall.

St. Luke's Hospital.—So early as the year 1731, in consequence of the insufficiency of Bethlem Hospital to contain the lunatics for whom admission was sought, a few benevolent individuals resolved on erecting a new asylum for their accommodation. A house was first built on the north side of Upper Moorfields, and opened for the reception of patients; but it was soon found not to meet the number of deserving applications, and in 1786 a more extensive building was erected at the corner of Old Street, at an expense of £55,000. It is a large and well-built edifice, extending nearly 500 feet in length; and is capable of holding upwards of 300 patients. In the vicinity of London are several private asylums for lunatics, on a larger scale than either Bethlem or St. Luke's; and, although some of them are respectable and well managed, yet there is strong reason to believe that there are others of a very different character. But this subject is at length before a committee of the house of commons.

Foundling Hospital.—In London, the proposal for a foundling hospital, which originated in the reign of queen Anne, and was strongly recommended by Addison, in the *Spectator*, was suffered to slumber for many years; nor was it until the year 1739 that captain Thomas Coram, who spent the whole of his fortune in the benevolent object, on presenting a memorial to his majesty, signed by twenty-one ladies of the first rank, and several noblemen and gentlemen, obtained a royal charter for its incorporation.

As the hospital was to be raised and supported by subscriptions, and a large sum was necessary in order to commence the charity on a scale sufficiently extensive, some time was necessary in order to raise the requisite funds. In 1740 the committee appointed to carry the measure into effect purchased fifty-six acres of land of the earl of Salisbury, on the northern side of Ormond Street, and extending to Gray's Inn, for the trifling sum of £7000: out of which the earl liberally gave £500 to the charity. On the 16th of September, 1742, the first stone of the new building was laid; benefactions continuing to

flow in, a chapel was built, to which Handel gave an organ, and the benefit of his oratorio of the Messiah; and, as he conducted the performance himself, he, in the course of a few years, produced to the charity £6,700.

Liberal as the subscriptions were, they did not keep pace with the demands on the hospital, which, before the end of the year 1752, had received 1040 infants, of whom 559 were then under its protection. Four years afterwards parliament voted a sum of £10,000 in aid of this charity, declaring that the enabling the hospital to receive all the children that should be offered was the only method to render the charity of lasting and general utility. The 2d of June was fixed for the general reception, and on that day 117 children were received; and the number increased so rapidly, that, before the 31st of December in the following year, the number amounted to 5510, and in 1760 to 6000. The indiscriminate admission of children, under a certain age, was found attended by an evil consequence, and in 1760 the law which authorised it was repealed.

Parliamentary aid still continued to be given to the hospital, until the improvement of its revenues, by letting ground on building leases, no longer rendered this necessary. The annual receipts of the hospital now amount to upwards of £13,000 a year, a sum which is considered as sufficient to maintain 500 children.

The foundling hospital is built of brick, and consists of two wings, with a chapel in the centre; the gardens and playground for the children are very large, and the situation is altogether as healthy as could be found in the heart of so large and so populous a city as London.

The Asylum, and London Orphan Asylum.—The foundling hospital is limited to the reception of infants—the asylum for female orphans at Lambeth, and the London orphan asylum for boys and girls, have been founded for the reception of destitute children, who are admitted at a more advanced age. Those of the Lambeth asylum, which originated with Sir John Fielding, between the age of nine and twelve; and, at the London orphan asylum, from seven to ten. They are both excellent institutions. The children are educated and industriously employed, until sufficiently old to be apprenticed out, when the utmost care is taken that they are provided with suitable situations.

Magdalen Hospital.—This excellent institution was commenced principally through the exertions of the Rev. Dr. Dingley, Henry Fielding, esq., and the unfortunate Dr. Dodd.

Since the institution of this society, on the 10th of August, 1748, to the 3d of January, 1822, 4986 young women who had strayed from the paths of virtue have been admitted, of whom 2343 have been restored to their friends, or placed in service; and it is an invariable rule, that no female shall be discharged unless at her own desire, or for misconduct, until means have been provided by which she may obtain an honest livelihood.

Since the Magdalen, which is situated in Blackfriars' Road, was instituted, two auxiliary societies have been formed in London; the Fe-

male Penitentiary at Pentonville, which was instituted in 1807, and the *Guardian Society*, for the preservation of the public morals, which, though an infant society, has admitted 681 females into the asylum in St. George's in the East, of whom 170 have been placed in service, 166 restored to their friends, and thirty-six sent to their respective parishes.

Asylum for the Deaf and Dumb.—It appears from medical enquirers on the subject, that in every country one person in less than 3000 is born deaf, and consequently grows up dumb. In France, an institution, under the venerable abbé l'Épée, had long been formed for the instruction of persons in such a state of mental destitution with the happiest effects, but it was not until the year 1792 that a similar establishment was formed in London.

The attention of the British public was first called to the deaf and dumb, by the Rev. John Townsend, and through his exertions an institution formed for their relief; and since the establishment of the deaf and dumb asylum in Kent Road, between 500 and 600 children have been instructed in writing, arithmetic, and the principles of religion. They have also been taught some useful manual occupation, by which, when they leave the asylum, they can earn a livelihood.

School for the Indigent Blind.—Several bequests have been made by benevolent individuals in London for the relief of the blind. Mr. Came, the gentleman who left annuities for the deaf and dumb, placed at the disposal of the Cordwainer's Company a fund for the relief of the blind; and Mr. Hetherington also left a large sum 'for the relief of blind persons of sober life and conversation, not receiving alms, nor being common beggars, nor having any annuity or income of £20, and resident in England.' To this fund, which is vested in Christ's Hospital, other benefactors have contributed, so as to enable the trustees to relieve 450 persons with an annuity of £10 each: another humane individual bequeathed annuities of the same sum to 175 blind persons, which are distributed by the Paper-stainers' Company.

The law of the school for the indigent blind, established in St. George's Fields in 1799, is to instruct persons, thus deprived of one of Heaven's best blessings, in a trade by which they may be able to provide for their existence. The establishment contains about sixty persons, who are employed in the manufacture of baskets, mats, thread, lines, &c., in which they can earn upwards of £600 a year, and thus afford a very essential return to the charity for the benefits they receive.

Philanthropic Reform Societies.—The investigations which of late years have taken place, on the subject of the criminal laws, have led to the establishment of several institutions in London, with the view of correcting offences by other modes than those of direct punishment; and for giving instruction to the most debased. The society for the improvement of Prison Discipline has in a few years effected a moral reform in our gaols, and established order and decency where vice reigned uncontrolled. The institution has also been instrumental in rescuing a

great number of juvenile offenders from the haunts of crime, and of preventing many distressed youths from resorting to criminal practices for support.

The *Philanthropic Society*, in St. George's Fields, was established in 1788, for the reform of discharged juvenile offenders, and the offspring of criminals, by providing them with suitable employment, and training them to habits of virtue and industry. Nearly 200 children of both sexes are admitted into this excellent institution, and instructed—the boys in printing, book-binding, shoe-making, &c., and the girls in needle-work, and other duties, to qualify them for household situations.

Another institution, of a similar nature to the preceding, is the *Refuge for the Destitute*. Although the object of this establishment is the reformation of juvenile offenders, of whom it is calculated there are 8000 in London, yet adults are sometimes admitted to its benefits: they are almost all criminals, who have either been recommended by the judges on their trial, or by the magistrates; or are so young, that it would be improper to inflict upon them the punishments annexed by law to their offences. In the early period of the institution, out of 131 that were admitted, forty-six proved incorrigible; but a better system of instruction and discipline has been adopted; and it appears, by evidence given before a committee of the house of commons, that nine-tenths of the criminals admitted are restored useful members to society.

Marine Society.—This excellent society, for fitting out boys for sea service, and affording an asylum to destitute sailors, was established in 1756. A ship is moored off Deptford for the reception of the boys, who are clothed, fed, instructed, and qualified for sea service; and so extensive have been the benefits of this charity, which was incorporated in 1792, that, since its establishment in 1756, 33,171 boys have been fitted out; and the number of men and boys who have been clothed and relieved by the institution is 72,531. The boys, who have the advantage of the instruction of the Marine Society's School, are invariably the best sailors, whether employed in the navy, the East India Company's service, or in merchant ships.

Institutions devoted to the general promotion of literature in London are not numerous. At the west end of the town is the *Royal Institution*, formed for the purpose of promoting science, and no establishment was ever better patronised in the outset, or more successful in its progress. It was first projected by count Rumford, in the year 1799, for the purpose of teaching, by courses of philosophical lectures and experiments, the principles of science, and their application to the improvement of arts and manufactures as well as the common conveniences of life. The society now possesses a valuable scientific apparatus, by means of which Sir Humphrey Davy made those experiments on the nature and properties of flame, which led to the discovery of the safety lamp; the library of the institution, though not large, is very valuable; and the courses of lectures which are annually delivered on science and literature are well attended.

Royal Society of Literature.—Towards the close of the year 1820, it was suggested to his majesty, that a society of literature, somewhat similar to the French Academy of Belles Lettres, might prove advantageous to the country; the king immediately expressed his approbation, and authorised the establishment of such a society under his immediate patronage. The objects of this institution are, to extend and unite the general interests of literature, to reward literary merit by patronage, to excite literary talent by premium, and to promote literary education, by bestowing exhibitions at the universities and public schools in cases of distinguished merit.

The patronage of his majesty has not been nominal; for, with that munificence which is a leading feature in his character, he has assigned to it a sum of 1000 guineas annually, to be divided among the associates distinguished for their learning, who are to contribute, within the year after their election, a literary essay to be printed in the Society's Memoirs of Literature.

London Institution.—Though commerce, like arts, is a jealous mistress, and requires almost undivided attention, yet the London merchants have not been so absorbed in the pursuit of gain as to neglect those refinements which have ever been attendant on commercial prosperity. In the year 1805 a number of gentlemen connected with the city associated together, for the purpose of forming an institution, calculated to promote science, literature, and the arts. The number of subscribers was limited to 1000; and the shares seventy-five guineas each; the subscription list was soon filled, and the institution opened with a good library in January, 1806, in a house, which formerly belonged to Sir Robert Clayton, in the Old Jewry; the library was afterwards removed to King's Arms Yard, Coleman Street, where it remained until a new and magnificent building was erected for the institution in Moorfields, under the direction of Mr. Wm. Brooks, the architect. This building is 108 feet in length, with two wings of sixteen feet each; the centre has a handsome portico, with pillars of the Tuscan and Corinthian orders, surmounted by a neat pediment. The interior arrangement is admirable; on the ground floor, in addition to the entrance halls, there are separate reading rooms for newspapers, magazines, and reviews, as well as for meetings of the committee, &c., and a noble staircase leads to the library on the first floor, which is ninety-seven feet long by forty-two wide; and the lecture room is sixty-three feet by forty-four. The library consists of a very extensive collection of modern works, and is particularly rich in topography; several courses of lectures on a variety of subjects are annually delivered, and in general are well attended.

The *Russel Institution*, in Coram Street, embraces the same objects on a smaller scale.

The *Red Cross Street Library* was founded by Dr. Daniel Williams, a dissenting minister, who dying in 1715—16, left it for the use of the ministers of his own persuasion. The library has been since considerably increased, and now contains nearly 17,000 volumes, comprising many valuable works on theology. Several interesting portraits of the nonconformist ministers and

curious manuscripts have since been added, to which persons are admitted under certain limitations, on procuring an order from one of the trustees.

Sion College, London Wall, is both a charitable and a literary institution. It was originally a hospital for blind paupers; and, after passing through various hands, was purchased for the purpose of erecting Sion College, for the use of the London clergy, who were incorporated by Charles I. The purchase was made in consequence of the will of Dr. Thomas White, vicar of St. Dunstan's in the West, who left £3000 for the purpose. The library was the gift of the Rev. John Simpson, rector of St. Olave's, Hart Street, one of Dr. White's executors; but it was afterwards considerably increased, both before and after the fire of London, which destroyed a considerable number of the books.

The *College of Physicians* was established in the reign of Henry VIII., when the number of members was limited to thirty. Charles II. increased the number to forty, and James II. extended it to eighty. The first charter was granted by Henry VIII. in the tenth year of his reign, in order, as the preamble states, to restrain the boldness of some wicked people, who all profess physic more for their own covetousness than out of any good conscience, when many inconveniences may arise to the ignorant, credulous, and common sort. This charter was ratified by an act of parliament four years afterwards, which enacted, that 'no person of the said political body and commonalty be suffered to exercise physic, but only those persons that be profound, sad, and discreet, roundly learned and deeply studied in physic.'

Towards the close of the seventeenth century the College of Physicians established three dispensaries, in many parts of London, for the purpose of supplying the poor with drugs at a low rate. Two physicians also attended at each of these dispensaries, in order to give advice to the poor gratis; but these benevolent views do not appear to have been long continued.

The College of Physicians was first held in Knight-riding Street, afterwards in Amen Corner; and, when the latter house was destroyed by the fire of 1666, they purchased some ground to the west of Warwick Lane, where Sir Christopher Wren erected an extensive building in Warwick Square; here the meetings of the society continue to be held, although a new college in Pall Mall East is one of the recent improvements of the metropolis.

Royal College of Surgeons.—Although the surgeons obtained an act of parliament in 1745, to separate from the Barbers' Company, with which they had been incorporated from the reign of Henry VIII., yet it was not until the year 1800 that they obtained a new charter, erecting them into a distinct college. The business of the new society was for some time carried on in the Old Bailey; but a new hall, of the Ionic order, has since been erected, on the south side of Lincoln's Inn Fields, which is enriched with a valuable museum, library, &c. Among its treasures is the extensive collection of the celebrated John Hunter.

Veterinary College.—Until of late years the art of farriery was left to the most ignorant and vulgar class of society, who, unacquainted with the principles of the science, or the properties of medicine, followed the mode of treatment which had been traditionally handed down to them, without any attempt at improvement, or enquiry how far it was proper. In 1791 a college for farriery was erected at the bottom of Gray's Inn Lane. The great object of this institution is, to form a school of veterinary science, in which the anatomical structure of quadrupeds of all kinds, horses, cattle, sheep, dogs, and the diseases to which they are subject, and the remedies proper to be applied, may be investigated and regularly taught. Parliament has frequently afforded liberal support, in order to prosecute this object. The building consists of a theatre for lectures and anatomy; a school, where from thirty to forty pupils are instructed in the veterinary art; and stables for sixty horses.

EDUCATION.—Independent of endowed schools, the parish schools, the Sunday schools, and those on the system of Bell and Lancaster, there are upwards of 4000 private schools in the metropolis and its immediate vicinity. The number of children educated in the last class, though not easily ascertained, can scarcely be less than 100,000.

According to a return, made to parliament in 1819, the proportion of scholars who are educated gratuitously, and those who pay for their instruction, in the several schools in Middlesex (which may be a fair estimate for London, as Southwark is not included), is 16,130, of whom 480 pay; the number educated in the unendowed schools is 24,289, of whom 6742 pay. The total number educated in the endowed and unendowed schools is 36,419, of whom 32,196 are educated gratuitously. In addition to the great number of poor children that are thus educated gratuitously, there are between 40,000 and 50,000 more, who are taught in the Sunday schools, which belong to almost every church and chapel, of whatever denomination, in the metropolis. The teachers of the Sunday schools, who amount to between 4000 and 5000, are all gratuitous, and very assiduous in their attendance.

Westminster School is certainly the first in point of rank in the metropolis. It is supposed to have been founded towards the close of the eleventh century, and to have been one of the public schools alluded to by Fitzstephen. It appears, however, to have declined; since Elizabeth restored or refounded it, in the year 1590, for the education of forty boys, who, in her honor, were called Queen's Scholars. From this period the school has been distinguished for its masters. See WESTMINSTER.

Christ's Hospital.—The foundation of Christ's Hospital was the last act of Edward VI.'s charity. It was only two days before his death that he signed the charter of incorporation for this school, when, with a sort of prophetic consciousness of its future benefits, he exclaimed, 'Lord, I yield thee most hearty thanks that thou hast given me life thus long to finish this work, to the glory of thy name.' It was erected 'for the

education and maintenance of the poor children of decayed merchants and tradesmen of the city of London,' on the site of a convent of Gray Friars, which had been annihilated by Henry VIII. Dobbs, the benevolent lord mayor, and the pious bishop Ridley, were among the earliest patrons of the hospital, and had no inconsiderable share in its formation.

So active also were the citizens in seconding the views of the monarch, that in less than six months the whole monastery of Gray Friars was converted into a hospital, capable of accommodating 340 boys. From this time the school has been continually increasing both in size and importance, so that the 340 scholars have been augmented to the number of 1150. The establishment will now accommodate 1156 children, including eighty girls who are provided for, without any expense to their parents or friends, and furnished with every thing necessary to forward their education. In the year 1809 there were only 1065 children upon the foundation, of whom sixty-five were girls. Of the 1000 boys, 161 were presented by companies, parishes, &c., 498 were sons of freemen, 239 were sons of non-freemen, and 102 sons of clergymen. The hospital was at first particularly intended for orphans; and, although their state of destitution is no longer an indispensable qualification, yet it is a strong recommendation; so that, of the 1000 boys in the school in 1809, there were 360 who were either orphans or had lost one of their parents. About a third part of the children, including all the girls, are educated at an auxiliary branch of Christ's Hospital, at Hertford, whence the boys, when sufficiently advanced in their studies, are transferred to London.

In 1672 Charles II. founded the mathematical school, for the instruction of forty boys in navigation, endowing the hospital at the same time with a sum of £1000 a year, for seven years. This school has seven exhibitions for Cambridge, and one for Oxford, in every seven years.

The government of Christ's Hospital, or the Blue Coat School, as it is more familiarly called, is vested in the lord mayor and aldermen, and twelve common-council-men chosen by lot; benefactors to the amount of £400 are also governors. There are four schools, for grammar, writing, mathematics, and drawing; the boys admitted to the mathematical school are compelled to go to sea, and, when their education is finished, they are placed with commanders of vessels by the governors, and equipped for their situation at the expense of the hospital.

The *Charter House*, situated on the north side of the square to which it gives its name, occupies the site of an ancient monastery for Carthusian monks, called the Grand Chartreux. It was part of the estate of the hospital of St. John of Jerusalem. Sir Walter de Manny, of Hainault, one of those gallant knights who served in the wars of Edward III., and one of the first that were honored with the order of the garter, and Michael de Northburgh, bishop of London, built and endowed the priory for twenty-four monks, in the year 1361. The monastery was suppressed in 1538; notwithstanding the obstinate resistance of the monks.

After the dissolution, the house passed into the hands of the Howard family, who resided at the house; and James I., on entering his new capital, on the 1st of May, 1604, paid his visit here to lord Thomas Howard, who entertained his majesty and suite for four days. Seven years afterwards lord Howard, who had been created earl of Suffolk, sold this estate, for the sum of £13,000, to Thomas Sutton, esq., citizen, and girdler, the founder of the present noble establishment. This he effected at the outlay of £20,000, independent of an endowment of £4493 19s. 10d. per annum. Mr. Sutton intended to preside as master of the hospital, but he died on the 12th of December 1611, six months after he had obtained the charter for its incorporation. The benevolent intentions of the founder were followed by the governors, who, in 1613, made an order, that no one should be admitted into the hospital, but only 'such poor persons as can bring good testimony of their good behaviour, and soundness in religion,' and 'no children whose parents have any estate in lands to leave unto them, but only the children of poor men that want means to bring them up.'

During the civil wars Cromwell was elected governor, and attended several of the meetings; since that period no event has occurred to injure this extensive charity. The number of scholars educated is seventy-three; of whom forty-four are on the foundation, and twenty-nine students at the universities, with an allowance of £20 per annum for eight years. Boys who give no promise of getting a living by their education, are put out apprentices, and have each a sum of £40 on leaving the school. Eighty pensioners are maintained on the endowment, who live in handsome apartments, and have all the necessaries of life provided for them; in order to enable them to clothe themselves, they have each an allowance of £14 a year, and a gown. The hospital is managed by a master and sixteen governors.

The charter house, though a venerable pile, has few vestiges of the ancient conventual building: the chapel is built principally of brick, and lined with wainscot; it has two aisles with Gothic windows; two of these, in the north wall, contain the arms of Mr. Sutton, in painted glass. There are several monuments in the chapel, particularly the tomb of the founder, which was erected at the expense of £400. The old court room is of the age of Elizabeth, and contains a profusion of coloring; the hall is spacious, and the apartments for the master convenient. The grounds, which are large, and well laid out, afford a fine promenade, though not one to which the public have access: and extensive additions are now making to the buildings of the establishment.

St. Paul's School was founded by Dr. John Colet, the eloquent dean of St. Paul's cathedral. So early as the reign of Henry I. there was a school here, and indeed it appears to have been an appendage to every cathedral; for, at a general council held at Rome in 1176, it was decreed that, 'every cathedral church should have its school-master to teach poor scholars and others, as had been accustomed, and that no man should take any reward for license to teach.'

Upon the foundation of this ancient school, dean Colet erected the present seminary, in 1509, for the education of 153 boys. He for this purpose conveyed the whole of his estate in London to the Mercers' Company, to whom he left the perpetual care of the school, and, when asked the reason of committing such trust to them, he observed, 'that there was no absolute certainty in human affairs; but, for his mind, he found less corruption in such a body of citizens than in any other order or body of mankind.' The company have always managed this fund most unexceptionably.

The rules for the government of the school, which are very minute, were drawn up by the dean himself, who directed that in the grammar school, there should be a high master, chosen by the warden and assistants in the Mercers' Company; he was to be 'a man hole in body, honest and virtuous, and learned in good and cleane Latin, literature, and also in Greke, as such may be gotten.' If a priest, he was to be one who had 'no benefice with cure, and no service that may let the due business in the schole.' Although dean Colet only lived ten years after he had founded the school, yet he had the satisfaction of receiving the congratulations of Sir Thomas More on its prosperity.

The only charge is 1s. on the admission of each scholar. After a classical education, on the foundation, the Mercers' Company have an indefinite number of exhibitions, of £50 a year to each, to either of the universities. In addition to the original fund of the dean, the school has had also several bequests of considerable amount, and a donation of £16,000 three per cents., by viscount Camden, for exhibitions of £100 a year each, at Trinity College, Cambridge.

The original school was destroyed by the great fire, and was rebuilt by the Mercers' Company; but the latter structure has given way to the mouldering hand of time, and is succeeded by a more elegant and more convenient building.

St. Paul's school has ranked among its scholars, Camden the antiquary, Milton the poet, the great duke of Marlborough, the philosophic earl of Orrey, Strype, the editor of Stowe's London, Dr. Edmund Halley, the celebrated astronomer; and several other distinguished persons.

Merchant Taylors' School is one of the most eminent seminaries of education in England. It was founded by the company in 1561, on a spot of ground on the east side of Suffolk Lane, Thames Street, formerly called the Manor of the Rose, belonging to the duke of Buckingham. The statutes of this institution provide that 100 boys shall be taught here at 5s. per quarter, fifty at 2s. 6d. per quarter, and 100 or upwards for nothing. The number on the establishment is seldom less than 300. The boys are instructed by a master and three ushers, in Latin, Greek, Hebrew, and other branches of useful and polite learning.

Sir Thomas White, who was a member of this company, and lord mayor in 1553, anxious to make still further provision for the youth educated at this establishment, founded St. John's College, Oxford, the scholarships of which are regularly supplied from merchant taylors' school.

A grand public examination of the scholars is held for the purpose every year, by the president and Fellows of St. John's College.

In order to provide exhibitions for the more intelligent of the unsuccessful candidates for these scholarships, an anniversary feast was begun in 1698, by gentlemen who had been educated at the school, which has, with a short interruption, been continued to the present time.

The London University and the King's College are entitled to a place in the enumeration of established schools, although of recent formation. The first comprises a handsome building in Gower-street, the second is held in a wing of Somerset House. Both were founded by subscriptions.

PRISONS. *The King's Bench.*—Besides the four principal prisons in the metropolis for debtors—the King's Bench, Fleet, Whitecross-street, and Marshalsea (the latter of which is of a mixed character), there are others belonging to minor courts, and numerous lock-up houses, which are a sort of purgatory through which the debtor passes to prison, unless he either settles with his creditor, or agrees to remain in the custody of the sheriff, which he can only do at a ruinous expense.

The king's bench prison, Southwark, is principally appropriated to the confinement of debtors, although persons convicted of libels and misdemeanors are sometimes confined here, as was the case with lord Cochrane, who contrived, however, to scale the walls, and take his seat in the house of commons.

At what time a prison for the court of king's bench was first erected in Southwark is unknown; but it was formerly customary for the court to be held in different places, and the prisoners to be confined in the nearest gaol. That there has been a prison on or near this spot, for some centuries, we learn from Stowe, who states that, in the reign of Elizabeth, several persons died there of what was called 'the sickness of the house,' which was occasioned by a large number of prisoners being confined in very small apartments.

The king's bench prison, which is surrounded by a lofty wall, contains 200 rooms, in which upwards of 500 persons have been confined at one time. Prisoners, who can give the necessary security, are permitted, during term, to go out for one day, and others may purchase the privilege, in a certain limited district, without the walls, which rules are denominated the rules of the king's bench; they include a space of nearly a mile square; it is not always, however, that the debtor restricts himself to these limits; for, when an application was made, some years ago, to the lord chief justice of the court, that the rules should be extended, he replied, that they were extensive enough, for that, to his knowledge, they reached to the West Indies. The emolument of the marshal of the king's bench prison, as appears by the Report of the Parliamentary Committee in 1815, amounted to £3590 a year, of which £872 arose from the sale of beer in the prison, and £2823 from the rules.

Fleet Prison.—The earliest record we have of the *Prisona de la Fleet*, as it was then called, is in the year 1169, although it is probable that it is of greater antiquity. The Fleet was at this

period, and for some centuries after, used as a state prison. It was long the receptacle for victims of the court of star chamber, and, when that odious court was abolished, was appropriated to debtors and persons committed for contempt of the court of chancery. In the riots of 1780 the prison of Fleet was almost wholly demolished. It has since been rebuilt, and protected in Fleet Market by a high wall. It consists of four stories of 180 feet each, containing 109 rooms, and is calculated, says a very recent historian of London, 'to hold comfortably 250 persons.'

The most serious evil formerly attending this prison was the facility with which illicit marriages might be performed here. Complaints having reached parliament, a committee of enquiry was appointed, who, on investigating the subject, ascertained on evidence that, from the 19th October, 1704, to 12th February, 1705,—2954 marriages were celebrated in this way in the Fleet, without either license or certificate of banns, besides others that were known to be omitted. Twenty or thirty couple were sometimes joined in one day, and their names concealed by private marks, if they chose to pay an extra fee. Pennant, at a later period, confirms this account of the daring manner in which the nefarious traffic was carried on. He says, in walking by the prison, in his youth, he has been often accosted with 'Sir, will you please to walk in and be married?' and he states that painted signs, containing a male and female hand conjoined, with the inscription, 'Marriages performed within,' were common along the building. A dirty fellow, outside, generally conducted you to the parson, a Bardolph looking fellow, in a tattered night-gown, who, if he could not obtain more, would marry a couple for a glass of gin or a roll of tobacco, though he has sometimes been known to marry twenty or thirty couple at from 10s. to £1 each. This glaring abuse was only put an end to by the marriage act in 1753.

Marshalsea Prison.—The court of marshalsea was at first instituted for determining the causes of the king's menial servants, and was under the control of the knight marshal of the household. It now has a jurisdiction extending twelve miles round Whitehall (the city of London excepted), for actions, debts, damages, and trespasses. The prison is appropriated to pirates and debtors; but it is small, inconvenient, and unhealthy, on account of the crowded state it frequently is in. A benevolent debtor, a Mr. Allnutt, who was for some time a prisoner in the marshalsea, had a large estate bequeathed to him during his confinement. He had learned sympathy by his sufferings; and, feeling for others' woes, left £100 a year for the discharge of poor debtors from this prison, by which means, every year, many obtain their liberation. The average number of debtors in this prison is stated, in the Parliamentary Report of 1815, to be about sixty.

Whitecross Street Prison.—When so much humanity has of late years been manifested by the legislature, in mitigating the severity of the laws against debtors, it is much to be regretted that the last prison erected for their confinement should unfortunately be of a very opposite description. The committee of the house of

commons appointed in 1815, to enquire into the state of the prisons of the metropolis, say 'they have much to regret, that those who have had the management of this building should have suffered a prison to be undertaken upon a plan so little likely to answer its object.' Whitecross Street is calculated to hold 400 prisoners, who are separated into different wards, accordingly as they are city or county prisoners.

Newgate.—So early as the year 1218 Newgate (so called from its being later built than the rest) was used as a prison, and continued as such until finally removed in 1777; but, although the gate was frequently rebuilt, yet there seems to have been no attempt at improving the apartments; and, so late as the year 1750, a pestilential disorder, called the gaol fever, broke out among the prisoners, owing to so great a number being confined in so small a space; the infection extended from the gaol to the sessions house, when Sir Samuel Pennant, lord mayor, alderman Sir Daniel Lambert, the chief justice of the court of common pleas, Sir Thomas Abney, Mr. Baron Clerk, Mr. Cox, under sheriff, several barristers, and nearly the whole of the jury, and several spectators, fell victims to this pestilential disease. Notwithstanding this melancholy event, twenty years elapsed before the first stone of a new prison was laid by alderman Beckford; and scarcely was the building finished, when the whole of the interior was demolished, during the disgraceful riots of 1780. To repair the damage that was done in a few days by those 'lords of misrule,' a London mob, £30,000 was necessary, which was chiefly supplied by parliament.

Newgate is now a massy and somewhat superb building, and perhaps the exterior appearance of no structure ever better corresponded with the purpose for which it is intended; there is a sort of gloomy grandeur and terror-striking uniformity in its outer walls, which would at once point it out as the abode of crime or misery. The interior of the prison is equally suitable to its objects; the cells for condemned malefactors are dark as the grave itself; and such is their impression, even on the most hardened, that Mr. Howard says, 'I was told by those who attended me, that criminals who had affected an air of boldness during their trial, and appeared quite unconcerned at the pronouncing sentence upon them, were struck with horror, and shed tears when brought to these darksome solitary abodes.'

Since the debtors have been removed to the new prison, in Whitecross Street, there is a better opportunity of classifying the prisoners; but they are still too numerous to enable the keeper to do this effectually: the average number of prisoners in Newgate is 420.

Adjoining the prison is the *Sessions House*, where there is a gaol delivery eight times a year, and yet the prisoners are so numerous that each session generally continues a fortnight or three weeks.

Giltspur-Street Compter, Newgate, was built according to a plan suggested by the benevolent Howard. It is confined solely to the city of London, and is a prison for offenders before trial, and a house of correction for such as have

been convicted and sentenced to various terms of imprisonment, of from one month to two years. It is also used for persons committed for assaults, night charges, disorderly persons, vagrants, and prisoners remanded for future examination; and numerous indeed are the persons who run the gauntlet of at least one night's lodging in Giltspur Street Compter; as it appears by the evidence of Mr. Teague, the keeper, that from the 1st of January, to the 31st of December, 1818, inclusive, 4581 persons were committed to this prison, of whom 1176 were for felonies, 637 for assaults, 1721 for misdemeanors, and 1407 as vagabonds.

Cold Bath Fields.—This prison, which is called the house of correction for the county of Middlesex, was, like Giltspur compter, built on the suggestions of Mr. Howard, though it is to be doubted, whether his benevolent objects have been realized.

It contains nearly 300 sleeping cells, and even these are sometimes found insufficient; so that barracks of wood, in each of which from fifteen to thirty persons sleep, are erected in the yard. In the year 1818, 3902 persons were committed to this prison, of whom 748 were females: and the average number of prisoners is about 400. The prison is almost entirely used as a house of correction; the prisoners were employed in picking old rope for oakum, until the year 1823, when a tread-mill capable of working 320 individuals was introduced. The annual expense of maintaining this prison is about £7000.

Clerkenwell Prison.—Bridewell was anciently not only the prison for the city, but for Middlesex also, and all offenders were sent there by the justices; but, says an old historian, 'These miscreants so increased that Bridewell could not contain them, nor employ them, neither were the governors willing to receive them.' It was therefore, in the year 1615, found necessary to build a new prison, and Clerkenwell was fixed upon as the spot. The building which, together with the ground, cost £2500 was defrayed by the justices and the inhabitants. The governors of Bridewell gave £500, which was principally expended in furnishing the prison. Previous to the erecting this prison there had been a sort of large watch-house called the cage, which was taken down in 1614.

The present Clerkenwell prison, which is nearly on the site of the old one, is a sort of auxiliary to Newgate, and includes prisoners waiting the Old Bailey sessions, who are always removed to Newgate on the Thursday previous to their commencement—others for petty larcenies who are detained for the Middlesex sessions, and prisoners committed for re-examination. The prison is capable of holding 350 prisoners, and, in the year 1818, 4012 persons were committed to the new prison Clerkenwell.

Tothill-fields Bridewell.—Upwards of 3000 persons are annually committed to this prison, and the average number of inmates is about 100, who for a day room have only one apartment, which measures no more than twelve feet by twelve and a half. This prison is wretchedly deficient in size and means of classification, and the place where it stands is unhealthy.

The *Borough Compter* is equally defective in point of classification, as prisoners of all ages, and of every grade in crime, are compelled to herd together.

The *Surrey County gaol*, in Horsemonger Lane, was built in 1781, and is appropriated to the confinement of debtors as well as felons. Adjoining to the prison is the sessions house, where all misdemeanors are tried, and the assizes for the county are sometimes held. On the top of this prison colonel Despard and his associates were executed in 1803.

The *Club Houses* belong to the west end of the town: we can only here find room for a brief notice of one or two of our older London taverns. No prince, or even knight, is now found to indulge in open revels, as prince Hal and Falstaff, and all 'the merry men of Eastcheap,' did at the Boar's Head; nor would our Raleighs, our Shakspeares, our Ben Jonsons, Beaumonts, Fletchers, or Seldens (had we any such) pass their evenings in taverns in Aldersgate Street, Fleet Street, or Cornhill, as the worthies we have just named, were in the habit of doing. Yet while it is remembered that Shakspeare, Ben Jonson, Beaumont, and others of their contemporaries used to assemble at the Mermaid tavern, Cornhill, and that under Sir Walter Raleigh an intellectual and convivial society of the spirits of the age was formed, called the Mermaid club, which, says Mr. Gifford, 'combined more talent and genius, perhaps, than ever met together, before or since, an interest will be attached to these spots.' Beaumont in a poetic epistle, from the country to Jonson, has described the 'wit combats,' as Fuller calls them, which in those days took place at the Mermaid tavern.

Ben Jonson was a great frequenter also of the Devil Tavern, by Temple Bar (now occupied by Child's Place), and the Swan Tavern, near Charing Cross. 'Rare Ben' appears to have owed much of his inspiration to sack and canary: in a MS. preserved at Du'wich, and said to be his journal, he ascribes the failure of some of his pieces to the death of the 'honest Ralph,' when he appears to have left the house; for, says he, 'I and my boys drink bad wine at the Devil.' This, however, was not always the case; for in another memorandum he says, 'The first speech in my Catiline, spoken to Sylla's ghost, was writ after I had parted with my friends at the Devil Tavern; I had drank well that night, and had brave notions.'

At a later period we find the men of genius mixing together at a tavern, many allusions to which are made in the *Spectator*, the *Tatler*, and other essays of the early part of the last century. Sir Richard Steele was fond of a tavern, and however ridiculous his uxoriousness may, and must appear, yet we have always thought a passage of one of his letters to his wife, written from a tavern, particularly expressive, when he assures her that he will be with her, not in half or a quarter of an hour, but 'within half a bottle of wine.'

The Kit Cat Club, 'the patriots who saved Britain,' as Horace Walpole designates them, originally met at the house of a pastry cook, in Shire Lane; yet they soon enabled Christopher

Cat, their host, to accommodate them better at the Fountain in the Strand, where their principal meetings were held.

A more ancient tavern, however, than any of these, was the Tabard, in the Borough (now the Talbot) the place whence Chaucer's pilgrims set out.

The taverns of the present day can scarcely boast of any literary associations; and although professor Porson frequented a house in the neighbourhood of Covent Garden, which now displays his portrait, it was rather to indulge his unfortunate propensities unrestrained than to seek society.

The first Theatres.—When dramatic representations ceased to be founded on religious subjects, they were no longer performed in churches, as was the case sometimes with the mysteries and moralities, and playhouses became necessary. The convenient form of the inns (still preserved in many of them) in London, with an open area in the centre, and a gallery on each side of the quadrangle, presented itself as a theatre ready made, with the exception of the stage: this was easily raised, either in the centre or on one side of the court, and thus many of our early dramatic pieces were performed. Even the first theatres were but a very slight improvement, for the area or pit was generally exposed to the air.

The first company of players that received the sanction of a patent was that of James Burbidge and others, the servants of the earl of Leicester, to whom queen Elizabeth granted a patent in 1574.

It appears from Stowe that the first players were 'ingenious tradesmen and gentlemen's servants,' who united in a company of themselves 'to learn interludes, to expose vice, or to represent the noble actions of our ancestors;' but that in process of time it became an occupation, when the players publicly 'uttered popular and seditious matters, and shameful speeches; and, these plays being commonly acted on Sundays and festivals, the churches were forsaken, and the playhouses thronged.'

When the first London theatre was built, or where it was actually situated, seems doubtful; but, early in the reign of Elizabeth, the Curtain, the Red Bull, and the Globe theatres, were all flourishing. Pennant was so anxious to identify Shakspeare with the Globe Theatre, that in a map he has given, purporting to be a plan of London and Westminster in the year 1563, he has introduced the singular anachronism of 'Shakspeare's play-house,' although the immortal bard was not born until the following year,—nor the Globe Theatre built on the site of an amphitheatre for bear-baiting in Bankside, Southwark, until the year 1596, 1598. The Globe was burnt down on St. Peter's day, the 29th of June 1613. The fire originated, according to Winwood, with the mimic discharges in Shakspeare's play of Henry VIII., when the rushes of the roof caught fire; and he adds, that the attention of the audience was so much engaged with the actors, that they did not notice it.

Near the Globe in Southwark, which seems to have been the first refuge of the regular drama,

were the Swan and the Rose, two very early theatres, and they appear to have been very attractive, if the assertion of Taylor, the water poet, can be relied on, that 'about the year 1596, the players began to play on the Bankside, and leave playing in London and Middlesex for the most part.' There were also either then, or soon after, six other theatres on the Middlesex side of the Thames.

If the Globe was rendered memorable by Shakspeare's connexion with it, the Curtain Theatre near Shoreditch, the name of which is preserved in the Curtain Road, had a similar distinction, by its being the place where 'rare Ben Jonson' acted, before he obtained celebrity as an author; yet the Curtain Theatre never appears to have flourished, although it had as an actor, Dick Tarlton, one of the best comedians of the time of Elizabeth. We can only further name the Red Bull in Clerkenwell, the Fortune, Barbican, the Blackfriars and the Whitefriars, as early play houses.

The first theatre in *Drury Lane* was a cockpit, which, hoisting a phoenix for a sign, was sometimes called by that name; it was not, however, until after the restoration of Charles II. that a house suitable for the accommodation of the public was erected. It soon shared the too common fate of the London theatres, and was burnt down in 1671; and three years afterwards it was rebuilt under the direction of that great architect, Sir Christopher Wren. This fabric, which was of considerable dimensions, and excellent in its internal arrangements, remained undisturbed until the year 1791, when it was determined to take it down and rebuild it on a scale better adapted to the increased population, and more refined taste of the age. In building the new theatre, in 1793, the architecture fell into an opposite extreme; the house was so enlarged in its dimensions as to be a theatre for spectators rather than hearers; and as the audience lost all those advantages which a convenient distance from the speaker gave in seeing the expression of his countenance, and hearing the varied modulations of his voice, the love of spectacle, which had already manifested itself, began to predominate.

As so many theatres had been destroyed by fire, it was determined to take every precaution against such a calamity in future. An iron curtain, which resisted the force of a sledge hammer, was constructed, so as to let down in a moment of danger, and separate the audience from the stage, while a reservoir was formed on the top of the house, filled with water sufficient, as the epilogue spoken at the opening of the theatre, by Miss Farren, gave assurance, to 'drown the audience in a minute.' On the first night the iron curtain was let down, and the stage was filled with water, on which a man rowed round with a boat; the managers boasted of their reservoirs,

A firm reliance,
Whose streams set conflagration at defiance.

But these were 'luckless words,' a 'bootless boast;' for, fifteen years afterwards, the whole fabric was burnt to the ground. This calamity

occurred on the 24th of February, 1809, and so rapid were the flames, that, although the fire did not break out until 11 o'clock at night, the immense edifice was reduced to a pile of ruins in less than three hours.

So various and so conflicting were the interests in the property of the theatre, that it was long before they could be reconciled; at length it was determined to rebuild it on a somewhat diminished, but more magnificent scale, and Mr. B. Wyatt was appointed architect for the purpose. From his plan, and under his direction, the present edifice was raised, and opened to the public on the 10th of October, 1812.

The rebuilding the interior of the theatre cost upwards of £14,000, and was executed in the short period of two months. It is due to the proprietors to state, that every alteration, while it adds something to the comfort of the audience, renders the ornamental decorations more chaste and elegant, and it is difficult to conceive a more beautiful structure in its interior than Drury Lane Theatre. The grand entrance, in Brydges Street, is through a spacious hall into a rotunda of great beauty; two noble staircases lead to the boxes, and to a saloon eighty-six feet in length, the walls of which are nearly covered with looking-glasses: the lobbies are spacious, and the house, which is lighted with gas, is well aired and ventilated. The exterior of the theatre is plain, but by no means inelegant. To the front, which is of the Doric order, a portico, surmounted by a statue of Shakspeare, was added in 1820, which is infinitely beneath the dignity of so noble a structure. Both the theatres of Drury Lane and Covent Garden enjoy the privilege of a royal patent, which authorises them to act dramas of every description, from tragedy, comedy, farce, operas, ballads, or spectacles of every class, provided they have previously been submitted to, and authorised by, the lord chamberlain.

In its general management, in the character of the performance, and in the periods at which the house is opened and closed every season, *Covent Garden Theatre* resembles that of Drury Lane; and while there is an honorable rivalry in the elegance of their respective structures, in the spirit with which new pieces are produced, or new actors of eminence are obtained, the proprietors are mutually accommodating to each other.

Covent Garden Theatre possesses a patent, originally granted to Sir William Davenant, and under which successive companies acted at the theatres in Dorset Street and Lincoln's Inn Fields; nor was it until 1733 that a theatre was built in Bow Street, Covent Garden, when Mr. Rich, who had formerly had the direction of Drury Lane Theatre, and afterwards that of Lincoln's Inn fields, removed to the new theatre, over which he presided until the year 1761, having been for fifty years the manager of a company under the patent granted by Charles II. In 1767 Mr. Harris, a young man who had not attained his twenty-first year, became a principal proprietor of this theatre, a considerable share of which remains in his family. Various improvements were made in the interior of this

theatre, and in 1792 Mr. Harris expended £25,000 upon it, when the prices of admission were raised. For some years Drury Lane had an advantage over Covent Garden, in possessing the talents of Mrs. Siddons, and her brother John Philip Kemble, who did so much to rescue the stage from the ridiculous and barbarous costume which had hitherto disgraced it; but in the year 1800 this company gained a great accession of strength in the person of George Frederick Cooke, whose debut on a humbler stage has already been noticed, and whose talents and dissipation made him so long an object of public admiration and regret.

On the 2d of September, 1808, this theatre, with all that it contained, was completely burnt to the ground,—and so rapid were the flames, that they threatened destruction to the whole neighbourhood, several houses caught fire, and were reduced to ruins, and the walls of the theatre falling twenty persons were killed. No time was lost in rebuilding this theatre, the first stone of which was laid on the 31st of December, 1808, by his present majesty, then prince of Wales. In ten months this immense edifice was finished, and opened to the public on the 18th of September, 1809, when a new danger threatened the proprietors, who, having built the theatre at an expense of £150,000, sought an indemnity, by raising the price of admission. This was warmly resisted by the public; and for more than a month the theatre was a scene of continued riot and confusion, which is known by the name of the ‘O. P. (old prices) war.’ At length a compromise was effected; but the injury done to the theatre, and the loss sustained from other causes, was long felt by the proprietors. This theatre, like that of Drury Lane, is continually receiving some new alteration or improvement in its interior, which is at once elegant and convenient.

King’s Theatre, Haymarket.—The opera had become so popular early in the last century, that a theatre was built for it in the Haymarket by Sir John Vanburgh, the architect. It was raised by thirty persons of rank, principally of the whig party, if we may judge by their inscribing the first stone with the words ‘Little Whig,’ in compliment to lady Sunderland, a celebrated beauty of the day. The money subscribed was £100 each, and the theatre opened on the 9th of April, 1705, with an Italian opera, which was far from being successful; it, however, continued under various managers, and with doubtful success, until the year 1720, when a sum of £50,000 was raised by subscription to support the Italian opera, which has ever since ranked as one of the favorite amusements of the fashionable world.

The Opera House was burnt down on the 17th of June, 1789; and on the 3d of April, in the following year, the first stone of the present structure was laid, by the earl of Buckinghamshire, with numerous inscriptions, one of which, ‘Prævalebit justitia,’ is excessively common place, and more applicable to a court of law, than a theatre erected for singers and dancers. Although the interior of the ‘king’s theatre,’ as it was now called, is well constructed, yet in its external ap-

pearance it was one of the most gloomy and clumsy buildings of the metropolis, until, in the recent improvements in this part of the town, a fine colonnade was added to the fronts in Pall Mall and the Haymarket, and the whole exterior remodelled, covered with stucco, and embellished with a relievo, by Mr. Budd.

The interior of the king’s theatre is magnificent and extensive. It contains 172 boxes, of which sixty-eight are said to be private property.

The little theatre in the Haymarket, as this house was called, to distinguish it from the opera-house, has long possessed an uninterrupted and extensive share of public favor. This theatre owes its rise to a speculating mechanic of the name of Potter; it was first raised in 1720, without any specific object beyond that of leasing it to the French players, as the foreign players and singers were then called, be their country what it might. It was opened on the 29th of December in that year. Foote had the old theatre taken down, and a new one built; but whether this was an improvement or not may be fairly doubted, as a more disagreeable or inconvenient structure can scarcely be conceived than the late theatre, opened in May, 1767. In nothing was the house more disadvantageously constructed than in the entrances, which were extremely narrow; a melancholy proof of this occurred on the 3d of February, 1794, when, his majesty having bespoken the play, the rush to the pit on the opening of the doors was so great, that fifteen persons were killed, and more than twenty others dreadfully injured. It has been severally under the management of Foote, the two Colmans, and Thomas Dibdin, all gentlemen of such talents, and so intimately acquainted with the detail of a theatre, as to ensure its success.

In 1821 the old theatre was taken down, and a neat, as well as a more commodious building was erected, from designs by Mr. Nash. In the front is a portico, supported by six columns: above the portico are nine circular columns, which are ornamented and connected with the entablature. The interior of the theatre, though it is not very conveniently arranged for comfort, is creditable to the artist, particularly the boxes, which are capable of little improvement.

English Opera House.—The Lyceum, or, as it has since been called, the English opera house, in the Strand, was opened in June, 1809. It did not at first meet with the patronage to which so laudable an attempt was entitled, and the plan has since been extended so as to include farcical burlettas and serious melo-dramas, as well as operas.

The lyceum was rebuilt a few years ago under the directions of Mr. Beazely, an architect whose talents in this line have been successfully exercised on several occasions in London, as well as in Dublin; and a neat portico was afterwards erected in the front.

This theatre was destroyed by fire in the month of March, 1830.

The *Surrey Theatre*, in Blackfriars’ Road, formerly called the Royal Circus, was built about the year 1779, for burlettas and equestrian exercises.

and was for some time under the direction of the British Tyrteus, Charles Dibdin. In 1805 it was burnt down, but was immediately rebuilt. It has recently been remodelled in the interior, and is one of the largest and most elegant of the minor theatres.

Astley's Royal Amphitheatre, Westminster Bridge (for it will not easily lose its name, although Astley is no more, and he is succeeded by Mr. Davis), was first opened about the year 1767 as a riding-school by Mr. Peter Astley, who had served in the army, and was a remarkably good horseman. The skill he displayed in managing the noblest of all quadrupeds attracted public attention, and Mr. Astley thought he might turn it to advantage by receiving money as an exhibition. An information was soon lodged against him, when, fortunately for him, his late majesty was riding over Westminster Bridge on a spirited horse, which proved restive and unmanageable even by the king, who was an excellent horseman. Mr. Astley happened to see him come up, and soon convinced his majesty of his skill in the managing of horses; the result was, that Mr. Astley got rid of the information, and in a few days obtained a license. The amphitheatre is now principally celebrated for its equestrian spectacles and gymnastic exercises.

The *Cobourg Theatre*, in Waterloo Bridge Road, which indicates its recent origin by its name, is an elegant little theatre, and was built in 1817. It is more remarkable for the beauty of the scenery than the merits of the dramas produced, or the talents of the actors.

Sadler's Wells Theatre was long celebrated for its Naumachia, which it exhibited by means of having a large current of water to flow under the stage. The real water, so long its greatest attraction, is now very seldom resorted to; and melo-dramas, burlettas, and pantomimes, are the favorite performances: in the latter description of pieces, Sadler's Wells theatre had, for many years, the benefit of Grimaldi's talents as clown. A dreadful occurrence took place at this theatre on the 15th of October, 1807, when some person, from mere wantonness, it is supposed, called out 'a fight,' which was mistaken for the word 'fire.' In vain did the manager come forward to assure the audience of the mistake,—they rushed from the gallery with dread impetuosity; and many, finding the avenues blocked up, leaped into the pit; in consequence of which, eighteen persons were killed, and several others wounded. The managers granted free benefits to the relatives of the deceased.

The *Adelphi Theatre*, formerly the Sans Pareil, in the Strand, and the *Olympic Theatre*, in Wych Street, erected by Mr. Astley in 1806, are small, but neat theatres, where burlettas and pantomimes are performed; and such are generally the amusements of the *West London Theatre*, in Tottenham Street, Tottenham Court Road, although it has occasionally been used for French subscription plays.

The *Royalty*, or *East London Theatre*, in Well Street, Wellclose Square, presented many amusing scenes during the war, of real, and not of mimic life, on account of the company by which it was frequented being principally sailors.

This theatre was built in 1787, with a view of performing the regular drama, which it was supposed the magistrates of the Tower Hamlets, in whose precincts it was, could authorize. Mr. John Palmer tried the experiment, which was only permitted one night. The performances were then confined to pantomimes and pantomimic burlettas, and that very rigidly. It was burnt in 1826; and a new theatre, erected from designs by Mr. Whitwell, fell to the ground shortly after its completion.

Royal Academy of Music.—Numerous as the literary and scientific institutions in the metropolis are, and highly conducive as they have been in promoting the objects for which they were established, one was yet wanting devoted exclusively to music. Such an institution has recently been formed under the immediate patronage of his majesty; and, though yet in its infancy, it promises to rank with the most flourishing institutions in the country. The object of the institution, which was founded in 1822, is 'to promote the cultivation of the science of music, and afford facilities for attaining perfection in it, by assisting in the general instruction of the natives of this country, and thus enabling those who pursue this delightful branch of the fine arts to enter into competition with, and rival the natives of other countries, and to provide for themselves the means of an honorable and comfortable livelihood.'

In order to attain these objects, a number of pupils, male and female, proportioned to the funds of the institution, are admitted, between the ages of ten and fifteen, and instructed by the best masters. The students pass an examination to ascertain if they possess a decided aptitude or disposition for music, before they can be admitted as candidates, and the election takes place by ballot; the subscribers voting according to the amount of their contributions. Each student, on being admitted, pays fifteen guineas to the funds, and ten guineas annually; but the fees of the children of professors of music are somewhat modified.

The noble mansion lately occupied by the earl of Carnarvon, in Tenterden Street, Hanover Square, has been fitted up for the purposes of the Academy. The rooms are of large dimensions, two of them being upwards of seventy feet each in length, and the other apartments afford every convenience. The professors, selected to superintend this establishment, are gentlemen of acknowledged talent.

Concerts.—So great is the love of music among the British nobility, or so liberal is their patronage of its professors, that the mansions of several noblemen are not only thrown open to their friends, whom they entertain with a concert, but they permit eminent musicians to take a benefit at their houses, which they cause to be fitted up for the purpose—a compliment not paid to any other class of individuals.

Independent of these concerts, and of those given by subscription at taverns and public rooms, there are several buildings in London devoted almost exclusively to musical entertainments; and numerous associations formed to promote the science. The Argyle Rooms, in

Regent Street, which were rebuilt in a splendid manner in 1818, were the first, but these have lately been destroyed by fire. They consisted of a grand concert-room, fitted up with an orchestra at one extremity, and boxes at the other, a ball-room of large dimensions, a drawing-room, and ante-room, and other apartments. These rooms were let for balls, concerts, and masquerades; and here the Royal Harmonic Institution, which is as much of a trading as a scientific association, was established. This society, which is managed by musical professors, gives lectures, publishes musical works, and purchases and disposes of harps, piano fortes, and other musical instruments. The *Philharmonic Society* was established in 1813. Other minor, but meritorious musical societies, we have not room to particularise.

PUBLIC GARDENS.—Vauxhall is the only one of those once popular places that retains its original character, the others having either entirely disappeared, and their sites been occupied by buildings, or they have sunk into common tea-gardens, where the humbler classes of society relax on a Sunday evening in summer, and indulge themselves with a glass of ‘home-brewed ale,’ or their wives and families with a cup of tea.

The most celebrated of the modern public gardens was Ranelagh, near Chelsea, once the seat of a nobleman of that name. On his death, in 1733, the estate was sold, and fell into the hands of some speculative gentlemen, who determined on forming it into a place of public amusement, similar to Vauxhall, which had just risen into popularity. In the fitting up the gardens, a magnificent rotunda was erected, 150 feet in diameter, in which was an orchestra, with numerous boxes and seats for the audience. The entertainments principally consisted of vocal and instrumental music. The rotunda was opened with a public breakfast in April 1742, which was followed by a concert. The inhabitants of London are, however, too much occupied to assemble in sufficient numbers for entertainments in the day, and the morning concerts at Ranelagh were soon relinquished for evening amusements. For some years the tide of fashion set strong in favor of Ranelagh, which was one of the most attractive resorts of the gay world; but afterwards, ceasing to be popular, the proprietors, in 1803, rased the building to the ground and sold the materials. The price of admission was half-a-crown.

Mary-la-Bonne Gardens occupied the site of Manchester Square; they were not formed into a place of regular amusement until the year 1737, when Mr. Gough the proprietor, who had before kept them gratuitously open, charged a shilling to each person, who in return received a ticket, which enabled him to have victuals or liquor to the full amount of the money paid on entering the gardens. Charles Dibdin and Charles Bannister made their debut, when youths, in *Mary-la-Bonne Gardens*, where very splendid fêtes were frequently given, particularly on the birth-day of his late majesty. Fire-works, and a representation of Mount Etna, were among the amusements. A sort of fair was once held in the gar-

dens, which were on that occasion fitted up with numerous shops and booths.

Islington was long celebrated for its public gardens; for, in addition to White Conduit House, and Bagnigge Wells, now mere tea-gardens, there were the New Tunbridge Wells, or Islington Spa, and Sadler’s Wells, which have been erroneously confounded as the same by most of the London local historians. The Islington Spa, a spring of chalybeate water, now in a small garden in Lloyd’s Row, near the New River Head, was discovered about the year 1690, and was opened to the poor gratis, provided they did not go out of mere curiosity, but with a certificate from a surgeon or an apothecary. A few years afterwards, as we learn by an advertisement of the year 1700, there was ‘music for dancing all day long every Monday and Thursday during the summer season,’ but, with a due regard to public morals, no masks were admitted. In 1733 the Islington Spa rose to the very height of popularity. Their royal highnesses the princesses Amelia and Caroline, having been recommended the use of chalybeate waters, repaired to Islington daily during the season of that year. Their example was soon followed by the nobility and gentry to such an extent, that the proprietor frequently took £30 in a single morning.

White Conduit House, where the humbler class of the inhabitants lie, merry-hearted, on a Sunday, is one of the most celebrated of all the tea-gardens in the neighbourhood of London, numerous as they are. The house takes its name from an old stone conduit, erected in the year 1641, which supplied the charter-house with water through a leaden pipe. The garden of White Conduit House is very spacious, and a neighbouring field was formerly attached to it as a cricket-ground, where a club of noblemen and gentlemen assembled to practise that game. This house was some years ago occupied by a Mr. Christopher Bartholomew, a gentleman whose unconquerable passion for gaming in the lottery reduced him to beggary, notwithstanding he was at one time worth £50,000, and had several lucky hits, one of which he celebrated by a fête champêtre in these gardens, ‘to commemorate the smiles of fortune,’ as the tickets of admission expressed it; it was, however, no wonder that he was ruined, as he sometimes spent 2000 guineas a day in insurance in the lottery, selling his stacks of hay or any thing to raise the money. The last thirteen years of his life were passed in great poverty, yet still his passion never forsook him; and when towards the close of his life he got about £600 by a new adventure in the lottery, and had purchased an annuity with the money, he sold it again to indulge in his fatal propensity.

There are several other tea-gardens much frequented on Sundays, but they appear rapidly declining in popularity; and Bagnigge Wells, once the residence of the celebrated favorite of Charles II., Nell Gwynne, is by no means respectably attended.

On the Surrey side of the Thames was formerly the Bermondsey Spa, in Grange Road Bermondsey. The spring, which was chalybeate, was discovered in 1770; but, some years previous

to this time, Mr. Thomas Keyse, the proprietor of the gardens, a self-taught artist, rendered them attractive by exhibiting a collection of his own paintings, principally subjects of still life, which possessed considerable merit. Keyse afterwards obtained a license for opening his gardens with musical entertainments during the summer season. Burlettas were also sometimes performed on small temporary stages, erected in the garden. Fire-works were occasionally introduced; and one season Mr. Keyse constructed an immense model, which covered four acres of ground, of Gibraltar, in order to represent the memorable siege of that place in 1782. The height of the rock was upwards of fifty feet, and the exhibition was as popular as it was creditable to the mechanical ingenuity of Mr. Keyse, but his talents were almost thrown away from the unfavorable situation in which they were exerted.

Independent of the public gardens in the immediate environs of the metropolis, attempts have been made to introduce them at some distance from town; and in the year 1742 Ruckholt House, Layton, Essex, which is said to have been once the mansion of queen Elizabeth, was opened by Mr. Barton, the proprietor, with public breakfasts, weekly concerts, and occasional orations, but the distance from town was unfavorable, and the entertainments were not continued more than four years.

Several of the taverns near London have large gardens, which are much frequented in the summer season, although they possess no attractions beyond the sale of refreshments.

Modern improvements.—If during a war, unexampled in its duration, and in the expense at which it was sustained, the British metropolis continued not merely to add house to house, but street to street, and to increase in magnificence, it was to be expected that, 'the piping time of peace' would give a new impulse to improvement. Such, indeed, is the case; and with the exception of the west end of the town, where Hyde Park seems to say, 'hitherto shalt thou go, and no farther,' we see London stretching out its Briarean arms in every direction, swallowing up every villa in its environs, and making them a part of the great capital. Islington has long been connected with London, which still, unsatiated, stretches northward. Somers' Town has no other division from the rest of the metropolis than a road, and Kentish Town, and Camden Town, will soon be closely connected with it. Hackney can scarcely be called a distinct village; and eastward we find a chain of buildings erecting, which will soon unite the adjacent villas with 'enlarged and still increasing London;' if we turn to the south we shall find the buildings increasing so rapidly, that Greenwich road will soon become one continued street.

Nor is it in the environs of London only that the spirit of improvement has gone forth, since it pervades almost every part of the metropolis. Within a few years Moorfields has been changed from a barren field to a neat circus; the Bank has been enlarged; the only private house remaining, built by Sir Christopher Wren, formerly the civic palace, restored in a style appropriate to its original grandeur, and numerous

other improvements in hand, and in contemplation. At the west end of the metropolis, the change is still more manifest. Charing Cross the only memorial of the affection of Edward I. for his beloved Eleanor, remaining in London, still retains its form, as does the equestrian statue of Charles I., cast by Le Sœur, but the alterations in the immediate neighbourhood are immense. Where the royal stables formerly stood (the Mews) splendid buildings are arising, and the church of St. Martin's in the fields will no longer remain like a candle hid under a bushel. Scotland Yard (so called from the kings of Scotland having a palace there, when they visited London) is now occupied by a fine street stretching towards the river, and the cathedral of St. Paul's can now be viewed from the admiralty.

Regent Street, which extends from Carlton House to Portland Place, though of varied architecture, some of which is not in good taste, is still a noble street, and leads to one of the greatest ornaments of the metropolis, the Regent's Park, around which noble terraces are springing up, as if by magic. This park, which is very spacious, is beautifully laid out; the grounds exhibiting a charming variety of lawns, lakes, shrubberies, &c. Such are a few of the improvements which have taken place under the auspices of George IV.; and if it cannot be said of his majesty, as of the Roman emperor, that he found a city of brick, and left one of marble, it cannot be denied that, while he has sustained the national honor abroad, he has done more to patronize literature, to advance the fine arts, and to improve the metropolis, than any sovereign that ever wielded the British sceptre; and should providence spare his majesty to complete his designs, and preserve the peace of Europe, we may anticipate that England will continue to be the first country, and London the first city, in the world: and in the last words of Paolo Sarpi, in speaking of his native Venice, we shall say of London, *Esto perpetua*!

PART IV.

GOVERNMENT OF THE CITY OF LONDON.

The office of *lord mayor*, as we have seen, was first recognised about the commencement of the thirteenth century.

According to the charter of king John the right of electing the mayor was vested in the citizens at large. After the common council was established, they appear for a time to have usurped the place of the general body of freemen; but, returning to a juster sense of the rights of their constituents, they passed, in 1475, a declaratory act of council, by which the election to the office was declared to belong to the mayor, aldermen, and common council, and the masters, wardens, and liverymen of the city companies, or, in other words, to the citizens at large, according to the fair acceptance of the terms, and thus it has ever since continued.

This right of election was accompanied with the discretionary power of continuing the same individual in office from year to year; the first lord mayor, Henry Fitz Alwyn, continued in office twenty-three years. The qualifications for

the office of lord mayor are, that the nominee shall be free of one of the twelve principal city companies; have served the office of sheriff (whence the saying, that such an one will be mayor before he is sheriff, meaning deridingly that he is not fit to be either); and be at the time of election an alderman of one of the wards of the city.

The election takes place on Michaelmas day, at a court of hustings held in the Guildhall, under the presidency of the sheriffs. All the aldermen who have not passed the chair, but have served the office of sheriff, are proposed successively in the order of their seniority, and the livery testify, by a show of hands, the degree of favor in which each is held. The sheriffs make a return to the court of aldermen, of the two members of their body, who have united the greatest number of suffrages; and it remains with that court to determine on which of the two the election has fallen. The candidates are not, however, absolutely bound by the show of hands, for it is open to any of them or their friends to demand a poll; a privilege which has, of late years, been frequently exercised.

The lord mayor, though elected by the citizens, must be approved by the king, or as has been invariably the case since Henry III., in the 7th of his charters to the city, permitted the alternative, by the lord chancellor on his majesty's behalf. Although the crown, however, does possess this veto, there is no instance of its having exercised it since the revolution.

The royal approbation having been obtained, the mayor elect, on the 8th of November, takes the oath of faithful administration, in presence of the citizens assembled in the Guildhall; and next day he is finally installed into office, by the barons of exchequer at Westminster.

The titles of right honorable, and lord, are generally believed to have been first given to the mayor of London by Edward III. in the last year of his reign, when a general subsidy was levied, in which individuals were assessed according to their rank and condition in life. The chief magistrate of London was, on this occasion, styled the Right Honorable the Lord Mayor.

The prerogatives of this office are of great extent and importance. As the sovereign's immediate representative, the lord mayor takes precedence of every other subject within the limits of the city. At a grand entertainment given about 1463, by the sergeants at law, at Ely House, Holborn, the lord treasurer, baron Ruthven, refusing to yield the most honorable place at table to the lord mayor, his lordship instantly withdrew, followed by the aldermen, sheriffs, and all the other citizens present on the occasion.

The monarch is, in England, but the first magistrate of a free people, elected by the people; and on his demise the lord mayor of London, as the greatest functionary next to the king, whose power is derived from the same source—as the acknowledged representative of a larger portion of the national will than any other officer of the state—takes the first place in the privy council, until the new sovereign is proclaimed, and, at his coronation, acts as chief butler.

As civil governor of the city, the lord mayor is the supreme head, without whose concurrence no act of the corporation is valid. He is, moreover, within the limits of the city and liberties, perpetual coroner and escheator, and chief justice in all commissions for trial of felony and gaol delivery. He is also judge of all courts of ward-mote for the election of aldermen; conservator of the river Thames and Medway; and perpetual commissioner in all affairs relating to the river Lea. In the military government of the city, his lordship is first commissioner of the lieutenantancy, which is invested with similar powers to those possessed by the lord lieutenants of counties.

The costume of the lord mayor is of a splendor becoming one filling so many high and dignified functions. His constant badge of office is a double chain of gold, or rich collar of SS, with a costly jewel appendant. On state occasions he is habited in a knotted gown, like that of the lord chancellor, or in one of crimson velvet. His more usual vesture is, in winter, a cloth scarlet gown with velvet hood; and, in summer, one of mazarine blue silk; both richly furred. In all processions where he is officially present the city's sword and mace are carried before him. By a grant of Edward III. the mace is permitted to be of gold or silver, a distinction conferred, we believe, on no city of England besides, except the archiepiscopal city of York. When on foot, his lordship's train is supported by a page. When he rides, it is in a state coach, of large dimensions and gorgeous appointments; richly carved and gilt; exhibiting in the pannels a variety of emblematic pictures, and drawn by four horses.

The person of the lord mayor is said to have been formerly held sacred and inviolable, but the instance chiefly relied on by historians scarcely warrants such an inference. It appears that, in the year 1399, Thomas Haunsart and John le Brewere, having forcibly resisted the mayor and sheriffs, in their endeavours to suppress a riot, were apprehended, tried at Guildhall, condemned to die, and beheaded in Cheapside; but it is much more probable that they were convicted for aiding and abetting the riot, than for any personal contempt of the chief magistrate.

A more unequivocal proof of the respect in which the chief magistrate's person was anciently held occurred in 1479, when Richard Hyfield was fined £50 for presuming to kneel too close to his lordship at St. Erkenwald's shrine!

The lord mayor is allowed a numerous suite of officers, for the support of his state and dignity; a chaplain, remembrancer, sword bearer, huntsman (called the common hunt), serjeant carvers, serjeants of the chamber, &c. In former times he had also his poet laureate and merry andrew, to assist in the productions of pageants on great occasions; but since these shows have gone out of fashion, neither poetry nor foolery appears to be any longer in request in city halls. On the list of lord mayor's laureates we meet with no less a name than that of Rare Ben; yet so unworthily had his merits been appreciated that, in a letter of that bard's which is still extant, he complains of the corporation for withdrawing

from him their 'chandlery pension for verjuice and mustard.' The pension, however, was not quite so chandlery, for it amounted to £33 6s. 8d. a sum which may at least stand comparison with what has been at any time allowed other laureates of higher degree. It was much more than was allowed even to the king's laureate in Ben Jonson's days; for, till 1630, the pension was but 100 marks, without a sip of the canary.

Previous to the fifteenth century, the lord mayor used to proceed by land to Westminster, to be sworn into office by the king, or, as latterly ordered, by the barons of exchequer; but in 1453 Sir John Norman introduced the custom of going by water. That he meant this aquatic excursion to serve as an emblem of the lord mayor's sovereignty over the Thames, in the same manner as the dukes of Venice used to wed the ocean, though sometimes averred by city poets, we dare not historically affirm; yet it is certain, that the mariners of the Thames felt so highly the honor conferred on their favorite element by Sir John, that they composed a song of triumph on the occasion, in which he thus figures as the hero:—

Row thy boat, Norman,
Row to thy Lemman, &c.

Meaning by 'lemman,' as it would seem, his fair one or bride the Thames.

In 1501 Sir John Shaw revived the custom of riding to Westminster Hall; and, for about two centuries, equestrian cavalcades were the fashion. In the reign of queen Anne the long-neglected barges were recalled into use, and ever since the procession has been by water. In recent times there was an instance of a lord mayor choosing to return by land; but such deviations, unless resorted to occasionally, for the purpose of showing the mere existence of the right, are not perhaps to be commended.

After this species of spectacle had fallen almost for more than half a century into disuse, the common council were all at once seized with a returning fondness for it; and in 1760 came to a resolution, recommending that pageants should be again exhibited for the entertainment of their majesties on lord mayor's day. The recommendation does not appear, however, to have been carried into effect, nor can it well be a subject of regret, that the city magistrates found then, as they have ever since done, more rational methods of manifesting their wealth and spirit.

The manner of celebrating the lord mayor's day at present is still sufficiently splendid to make it an object of attraction to the multitude. About noon, the lord mayor elect, the past lord mayor, the aldermen, sheriffs, and other official dignitaries, after attending divine service at the parish church of St. Lawrence Jewry, proceed in their carriages from the Guildhall to the Three Crane Stairs, where they embark on board a magnificent state barge, provided for the use of the chief magistrate; and being joined by the different city companies, in barges of their own, and all more or less gorgeous, the aquatic procession moves forward to Westminster, with bands of music playing, and flags and pendants flying from every mast. When the ceremony in the court of exchequer has been gone through, the civic fleet

returns to Blackfriars Bridge, where the mayor and citizens land, and are received by the Armourers' Company, which takes the lead in the procession back to the Guildhall. The armourers are generally preceded by two or three persons on horseback, in different sorts of showy armour; and these form row by far the most attractive part of the spectacle. The other companies follow on foot; the mayor and sheriffs in their state coaches; the aldermen and other persons of distinction in their private carriages; and these, with their numerous officers and attendants, in their various motley ware, make up what is now called the lord mayor's show.

At Guildhall a sumptuous dinner is provided at the expense of the lord mayor and the sheriffs, which is generally graced with the presence of some of the princes of the blood and ministers of the crown, the foreign ambassadors, and a number of the most distinguished nobility and gentry. Should it be the first lord mayor's day after a coronation, it has been customary for the sovereign himself to honor the banquet by partaking of it. The number of persons invited is seldom less than 1200, and the usual cost of the feast is about £3000. When the king is present the expense is much greater. The entertainment given to George II. cost £4890; and that to George III., which was of singular magnificence, £6898. All the companies give besides sumptuous entertainments at their respective halls, which are supposed to cost £10,000 more.

The festivities of the day, at Guildhall, are concluded by a grand ball, at which the lady mayoress presides. Among the entertainments anciently provided for this part of the evening, the lord mayor's fool had a very singular feat to perform. He was bound by the tenure of his office, to leap in his motley robes into a large bowl of custard, a jest so exactly suited to the taste of former times, that it was not easily made stale.

In 1810 the regular expenses of the mayoralty were found to be about £12,000 and his official receipts, including a sum allowed to him by the city, and the value of some appointments in his gift, did not exceed £6500. The common council, on receiving this report, voted an additional allowance of £1500 per annum.

The city *remembrancer* is the lord mayor's monitor; a part of his duty being to remind his lordship of the days on which he has to proceed with the aldermen on city business. He is also a guardian of the city rights, and is appointed to attend the sittings of parliament, to see that the privileges of the city are not infringed, or its interests injured by the proceedings of the legislature.

Sword bearer.—The sword is an emblem of authority as well as of justice, and is borne before the lord mayor to express that they are both united in his office. A writer on armoury, who distinguishes how swords of state should be borne before persons of different ranks, says that 'the city sword bearer must carry the sword upright, the hilt being holden under his bulk, and the blade directly up the midst of his breast, and between his brows.' The sword bearer has his table at the expense of the lord mayor, to whom

£1000 a year is allowed for the purpose, exclusive of a sum of money for the residence of the sword bearer.

Aldermen.—The division of the city into wards, and the appointment of aldermen to govern them, were undoubtedly, as before observed, of Saxon origin; but it would seem not to have been long before the office assumed a character somewhat foreign to the genius of Alfred's institutions. So wise a prince could not have intended that an office of this importance should be filled without any regard to merit or capacity; and yet almost the first thing we read of the office is, that it might be acquired by any one, either by inheritance or purchase. So much, indeed, was this the case, that the wards were called after their respective proprietors, and changed names as they changed; thus the ward of Castle Baynard was once called Simon Hade-stock's Ward; the ward of Cheap, Henry de Frowycke's Ward; the Tower Ward, William de Nadestocke's Ward, &c. The abuses which necessarily arose, from this proprietary system, led to repeated efforts on the part of the citizens to change the tenure of the office; and at length, from one of those coalitions between the crown and the people which are not uncommon in the history of revolutions, the right of property was in the reign of Edward II. wrested from the aldermen, and the citizens of each ward were declared to have the power of electing annually the alderman who was to preside over it. So frequent an exercise, however, of the elective privilege, had also its peculiar inconveniences; and in 1394 it was ordered by parliament that in future the alderman should continue in office during life or good behaviour, and so the law still continues.

In elections for aldermen, the right of voting is confined to freemen who are resident householders of the ward paying scot and lot, and an annual rent of not less than £10 a year.

It is not necessary, however, that the person elected should be a resident of the ward. Citizens of eminence often become candidates for the aldermanship of wards with which they have previously had no particular connexion. Should a person decline the office of alderman when elected to it (which is, however, rarely the case) he may be fined; there is even a precedent for imprisonment.

Each alderman has the active direction or wardenship of the affairs of his ward, under the general superintendence of the lord mayor; and is assisted by one or more deputies, appointed by himself from among the common councilmen of the ward. Every ward, too, has its court of wardmote or common hall, with which the alderman may advise on all matters touching the common welfare.

The privilege of acting as magistrates in the city was formerly confined to the lord mayor, the recorder, the aldermen who had passed the chair, and the nine senior aldermen below it; but in the year 1741 George II. by letters patent empowered all the aldermen of London, without distinction, to act in future as justices of the peace within the city and its liberties.

The dignity of alderman, like that of the lord

mayor, had once more than ordinary protection, and in those turbulent times, when personal feeling and resentment usurped the place of law and justice, it is recorded that a citizen was imprisoned and his right hand cut off for assaulting an alderman. Resistance to the authority of an alderman was commonly punishable with the loss of freedom, and imprisonment for a year and a day.

The costume of the aldermen is a cloth gown of violet or scarlet, lined with silk or furred according to the season. On one occasion an alderman, who neglected to line his cloak according to the established mode, was condemned by his brethren to a summary punishment, amusingly characteristic of the claims of this respectable body to the character which Shakespeare has given of them, as being with fat capon lined. They decreed that the whole court should go and breakfast with him.

Wards.—The city and liberties are divided into twenty-six wards or aldermanries; which, considered with respect to the number of members they respectively return to the common council (excepting Bridge Ward without, which has no representatives), rank in the order in which we shall here take notice of them. The number of councillors for each ward is denoted by the numbers within a parenthesis.

The wards of Farringdon within and without formed originally but one ward, the aldermanry of which was purchased by William Faryngdon, goldsmith, and sheriff in 1279, and remained in his family for upwards of eighty years. The tenure by which it was held was, the presentation at Easter of a slip of gilliflower, then a flower of considerable rarity. In consequence of a great increase in the population of this portion of the city, it was, in the seventeenth of Richard II., divided into two wards, and a separate alderman assigned to each. Farringdon Within (seventeen common council-men) comprehends that part of the city which lay immediately within the walls on the western side. Its locality is well marked by a small stone monument in Pannier Alley, representing a young Bacchus seated astride a pannier or basket, with this inscription underneath,

WHEN YE HAVE SOUGHT
THE CITY ROUND,
YET STILL THIS IS
THE HIGHEST GROUND,
AUGUST THE 27,
1688.

Farringdon Without (sixteen) includes all that part of the city which lay without the walls to the westward, as far as Temple Bar. Till 1484, Serjeants' Inn was called 'Faryngdon's Inn.'

Bridge Ward Within (fifteen) is of extensive limits; and includes the spot 'Where London's column, pointing to the skies,' does not lie so utterly as Pope's lines have made it the fashion to believe. It was one of those wards entirely destroyed by the fire; it takes its name from London bridge, the whole of which from the Southwark end it includes.

Bishopsgate Ward derives its name from the

gate which formerly divided it, and which is supposed to have been constructed by some of the earlier bishops of London. Though the gate no longer exists, yet the boundary is still marked by the appellations of Bishopsgate Within and Bishopsgate Without. The buildings in this ward are among the most ancient of the metropolis, the great fire not having extended its ravages far in this direction, and not at all to the parts without the gate. During the course of more than a century, every alderman who has presided over this ward has served the office of lord mayor.

Bread Street Ward (twelve), which is nearly in the centre of the city, takes its title from the bread market, which formerly stood on the present site of Bread Street: for, in ancient times, the bakers of London were not allowed to sell bread in their shops or houses, but only in the open market. At a still earlier period, this ward appears to have been the domain of that notable hero of fable, Gerard the Giant. In Gerard's Hall (now occupied as an inn) there was kept, for a long time, an immense fir pole, some thirty or forty feet long, with which this redoubtable monster used to sally forth to battle, as also a ladder by which he occasionally permitted the pigmy order of mankind to ascend to the top of his faulchion, to take a bird's-eye view of the metropolis! Stowe has made sad havoc with this pretty story. 'Gerard's Hall,' he says, 'is a corruption of Gisor's Hall, once the property of John Gisors, mayor of London in 1311; the giant's faulchion, nothing but an old Maypole; and the ladder, the same which was used to deck the said Maypole, when erected on the green.'

Cheap Ward (twelve) takes its name from the Saxon word *chepe*, a market; applied to our present Cheapside, which was formerly called 'West Chepe,' to distinguish it from another market in East Cheap. Before the stream, called Walbrook, which intersects this ward, was covered in, it is said, that barges used to be towed up it, from the Thames, as far as Bucklersbury. The Standard or Cross, in Cheap, is familiar to the readers of history, as the ancient place for execution within the city.

Tower Street, Broad Street, and Cripplegate, wards hold the same rank in the city representation as those of Bread Street and Cheap, each returning twelve members to the common council.

Langbourn Ward (ten) takes its name from a brook which formerly ran from Fenchurch Street, where it broke out, to the Thames. The stream spread so much near the head of the spring that the neighbourhood received the name of 'Fenny-about,' and this circumstance is still perpetuated in Fenchurch Street.

Castle Baynard Ward (ten) takes its title from the ancient castle of that name, which stood on the site of the present Cannon Wharf, and was originally built by William Baynard, a soldier of fortune, who accompanied the Norman William to England. It passed afterwards into the hands of the Fitzwalters, who occupy a prominent part in the early history of London. They possessed in virtue of this castellary the

honor of being hereditary standard bearers of the city. When in times of war the banner of St. Paul was unfurled, it was consigned with great ceremony by the lord mayor and aldermen to the hands of the knight of castle Baynard, at the great west door of St. Paul's, the mayor addressing him in these words: 'We give you, as to our Banneret of fee in this city, the banner of this city to bear and govern to the honor and profit of this city, to your power.'

Castle Baynard was entirely destroyed in the great fire of 1666, but before that had become greatly dilapidated.

Billingsgate Ward (ten), which 'the ladies of the British fishery,' as Addison has humorously designated them, have rendered of such notoriety, boasts of having had for alderman the patriotic Beckford.

Vintry Ward (nine) comprises a part of the north bank of the river Thames, where the merchants of Bourdeaux formerly bonded and sold their wines.

Dowgate Ward (eight) take its name from *dwyr-gate*, the ancient water gate, which is by Stowe supposed to have been the Watling Street ferry across the Thames. The patriotic Sir John Barnard was alderman of this ward.

Candlewick (now Cannon) Street, the name of which is preserved in the ward of the city (eight) was formerly much occupied by wax and tallow chandlers, trades of some importance in London, until the year 1548, when, by order of Henry VIII., the burning of candles in the church on Candlemas day was ordered to be discontinued.

Cordwainers' Ward (eight) derives its title from Cordwainers' Street (now Bow Lane), which formerly was a great mart for curriers, shoemakers, and other workers in leather.

Walbrook Ward (eight) was so called from the brook which intersected the city wall at Dowgate, and flowed into the Thames.

Aldersgate Ward (eight) takes its name from one of the oldest gates of the city, and, like that of Bishopsgate, includes streets and lanes both within and without the walls.

Cornhill Ward (six) took its title from the corn market, formerly held in this street, or rather in the church-yard of St. Michael's, adjacent to it.

Aldgate Ward (six) consists of a *soke*, which was originally attached to the gate of that name, on the east of the city. When Matilda, or Maude, the queen of Henry I., founded the priory of the Holy Trinity, called Christ Church, on the ruins of which the present St. James's church, Duke's Place, was erected, she assigned for its support, with the consent of the king, her husband, the port and *soke* of Aldgate. The priors do not appear, however, to have ever claimed, or been admitted to a place among the magistracy of the city, on account of the *soke*-manry; but having afterwards obtained a grant of the Knights Guild, a lay corporation, since better known by the name of Portsoken Ward, the prior of Christ Church became, in virtue of that knighten guild, an alderman of the city. When he sat or rode with the alderman, he doffed his spiritual habiliments, and wore the

costume of his lay brethren. Eustacius, who was prior in 1264, having some scruples about this occasional divestiture, appointed Theobald Fitz Jocanis to be the alderman of Portsoken Ward, under him. It is in allusion to this duality of office that in the inscription over the door on the north side of the chancel of St. James's church, Duke's Place, 'consecrated,' as we are told, 'to the eternizing the memories' of the worthies by whom it was erected, the parish clerk (for who else could pen such strains?) thus proceeds:—

And, since I touch antiquity so near,
Observe what notes remarkable appear;
An alderman of London was, at first,
The prior of this church; falling to th' worst,
'Tis new raised by th' encouragement and care
Of a lord mayor of London, which is rare.

Queenhithe Ward (nine) takes its name from the harbour of Queenhithe, which was formerly a principal place for loading and unloading goods, and was so called because the customs payable there were assigned by king John to Eleanor his queen, and to her successors in the queenly dignity, for their own separate use. The ground, for a considerable space around the harbour, formed a soke which was governed by the queen's bailiffs. In the time of Henry III. it came into the hands of Richard, earl of Cornwall, who conveyed it for an annuity to the mayor and commonalty of London.

Coleman Street Ward (six) is supposed to derive its name from a family of the name of Coleman, who lie buried in the church of St. Margaret, Lothbury. Stowe and his continuators suppose the first of the Colemans to have been a builder; but is it not as probable that he might have purchased the Aldermanry, and given his name to it, as William Faryngdon did to the wards of Farringdon?

Portsoken Ward (five) is situated beyond the ancient city walls, and is of considerable length, extending from Aldgate to Whitechapel Bars, and from Bishopsgate to the river. The origin of the ward of Portsoken, which signifies 'franchise at the gate,' is by Stowe ascribed to the age of king Edgar. He relates that thirteen knights or soldiers, who were well-beloved by the king for services they had done, besought from him the grant of a portion of land on the east of the city, which had been left desolate and forsaken by the inhabitants 'by reason of too much servitude,' with 'the liberty of a guild for ever.' The king granted their request, on condition 'that each knight should victoriously accomplish three combats; one above the ground, one under ground, and the third in the water; and after this, at a certain day, in East Smithfield, that they should run with spears against all comers; all which,' adds Stowe, 'was gloriously performed. The king accordingly incorporated the knights, by the name of the Knighten Gild.' The southern boundary of the ward was fixed in a manner as singular as the conditions on which the whole was granted; it was to extend as far into the Thames as a horseman, riding into the river at low water, could throw his spear. This grant of Edgar to the knights was confirmed by Edward I.

the Confessor, and afterwards by William Rufus, and Henry I. During the reign of the latter monarch, in 1115, the brethren of this guild, who were then called 'burgesses of London,' gave the entire soke and its appurtenances to the church of the Holy Trinity, within Aldgate; and the whole possessions of the guild were afterwards by royal charter confirmed to the brotherhood of that church, the prior of which was invested with great ceremony, and allowed to govern the ward, and exercise the duties and participate in the honors of an alderman of London. Since the suppression of the monasteries, however, the ward of Portsoken has had a lay governor, in the person of its alderman.

Lime Street Ward (four), though without a church, or a complete street, runs through several parishes. It is so small, and used to be thought of so little account, though now the seat of as much wealth as any ward of the city, that in 1371, when the city was assessed in £635 12s. for the war in France, the proportion required from Lime Street ward was only £1 14s. It is generally said to have derived its name from being a place for 'the making and selling of lime;' but the conjecture, we suspect, has no other authority than the identity of the name. The circumstance of the ward's running stragglingly through so many parishes is opposed to such an origin; besides, lime was not a commodity in such general use, five centuries ago, as to give a name to a market. May the ward not have had as sylvan a parentage as the village of Limehouse, which is a corruption of Limehurst, the Saxon term for a grove of lime trees? It is not more unlikely that the manor of Leadenhall, which lay chiefly in this ward, should of old have boasted of its limes, than that that present sink of filth and wretchedness, Petticoat Lane, should once have been, as thus described by Stowe; with 'hedge rows and elm trees on both sides,' and 'pleasant fields to walk, insomuch that gentlemen used to have houses there for the air.'

Bassishaw Ward is the smallest ward in the city; its name is a corruption of Basinges-haugh or hall, a large mansion, formerly belonging to the Basinges, a family, as Stowe assures us, of 'great antiquity and renown.' In the reign of Edward III. Basinghall became the residence of Thomas Bakewell, who gave it his name; and, in the succeeding reign, it was purchased by the city, together with another house, two shops, two gardens, and other appurtenances in the adjoining parishes of St. Laurence and St. Michael, for the small sum of £50. It was converted by the city into an exclusive market for the sale of woollen cloth, under the name of 'Blackwell Hall,' and its privileges secured by severe penalties. The whole of Bassishaw Ward is comprised in the two precincts of Basinghall Street.

Bridge Ward, without, includes the principal part of the borough and liberties of Southwark, and a much larger population than any of the other wards; it gives also the title of 'Father to the City,' to the alderman who rules over it; and yet it is totally unrepresented in the court of common council. Southwark, although so long annexed to London, has never been incorporated with it; its civil government is managed by a

bailiff appointed by the court of mayor and aldermen; and the office of alderman, being a mere titular sinecure, is always given to the senior alderman of the city, as the best entitled to enjoy the *otium cum dignitate*.

The court of lord mayor and aldermen, besides having the power of appointing the recorder and several other city officers, and suspending them for misconduct, possesses also a considerable portion of the executive authority, for by this court all leases and other instruments that pass the city seal are executed.

The court of aldermen is not an open court, but its proceedings on political questions, or any others of general interest, invariably transpire; and, indeed, while the press possesses as it does at present the eyes of Argus, with the hands and heads of Briareus, it is difficult to conceal any subject of importance from the public.

According to the institutions of Alfred, the sheriffs throughout the whole kingdom were elected annually by the community at large; in the counties by the freeholders, and in London by the citizens, without distinction. This privilege however has been often invaded. The freeholders of Middlesex, for example, were arbitrarily deprived of their right of appointing their own sheriff, when Henry I. transferred it in perpetuity to the corporation of London; and the citizens of London themselves paid to king Stephen 100 marks of silver for the right of nominating the sheriffs for the city and county of London. But, when the more general usurpation of Edward II. took place, the sheriffalties of London and Middlesex were the only ones exempted.

For a considerable time the right of voting for sheriff remained, as at first, with the general body of the citizens; but a change to a more manageable order of things was desired, and the mayor began accordingly with summoning, to the meeting for the election of sheriffs, only a few of the 'wealthiest' and 'discreetest' men out of each ward; 'sometimes more, sometimes less.' This select number he was pleased to style 'the commonalty.' At first the number of select citizens summoned from each ward was only two; but, in the sixth of Edward II., we find that it had been increased to twelve. This increase led, however, to some apprehensions for the stability of the system, and the number was again reduced in most of the wards; in some to ten and eight, and in the smaller wards to six. The commonalty of London having at length found favor at court, by the services which they rendered in elevating Edward IV. to the throne, that monarch so far restored the election of sheriffs to its ancient footing as to direct that it should in future be vested in the mayor, aldermen, common council, and liverymen of the different companies; and thus it has remained to the present day.

A mere freeman of London is excluded from voting; he must have taken up his livery to be entitled to the privilege. An unsuccessful effort was made, in the time of the commonwealth, to have the election thrown open to all freemen; but the limitation appears ever since to have had the sanction of popular approbation. The election, as it now stands, is certainly on a broad

enough basis, for every useful purpose. When 7000 or 8000 resident liverymen can be polled, at a disputed election, the addition of 1000 or 2000 votes of mere freemen might oftener endanger than strengthen the popular side of a question.

After the mayors had been thus deprived of the absolute appointment of the sheriffs, the citizens allowed them, out of courtesy, to *nominate* one of the sheriffs. So far did the citizens carry this courtesy of theirs, that, from the days of Edward IV. to the year 1641, they appear never once to have rejected the sheriff nominated, or, as the fashion was, drunk to, at some previous city feast, by the lord mayor for the time being.

From so invariably approving for so long a period of the mayor's nomination, it is not surprising that it should at last have been considered as a matter of course, that the person drunk to by his lordship should be one of the sheriffs. So much was this the case, that, in the time of queen Elizabeth, there are instances of the mayor's nominee signing the usual bonds to hold the office before he was confirmed by the livery. When at length, however, the open attempt of Charles I. to establish despotism in the country made it of importance to shut up every avenue to undue influence, the citizens showed that they had not forgotten that the right of rejecting the nomination of the mayor was one which they might still exercise. From 1641 to 1663 they uniformly rejected the person nominated by the mayor, and appointed two sheriffs of their own selection. The Restoration having brought for a time courtesy again into fashion, the lord mayor's nominees were for many years, with but one exception, confirmed by the livery. In 1680 the citizens again made their own choice. They rejected the nominee of the lord mayor, and chose Slingsby Bethel and the unfortunate alderman Cornish as sheriffs, both of them persons distinguished for their opposition to the court. It was during their sheriffalty that lord Stafford was condemned to the block, for his supposed share in the popish plot; and the sentence ordered to be executed with all those horrid aggravations, the stain of which it remained to the present age to remove from the statute book. The king thought fit to commute the sentence into beheading merely; the sheriffs Bethel and Cornish protested against the right of the king to order any such mitigation of the sentence; and it was not till the house of commons had declared that they would be 'content' with the head of their victim, that the sheriffs yielded the point.

The court party having, in the interval between the election of these sheriffs and the election of mayor, mustered in unusual strength, they succeeded in raising to the mayoralty Sir John Moore, a person so completely under Mr. Secretary Jenkins's management, that it was resolved to push the old usage about the nomination of sheriffs to its utmost possible extent. 'When the day came,' says Burnet, who relates the facts with great impartiality, 'in which the mayor used to drink to one, and to mark him out for sheriff, he drank to North, a merchant, that was brother to the chief justice. Upon that, it was

pretended that this ceremony was not a bare nomination which the common hall might receive or refuse, as they had a mind to it; but that this made the sheriff, and that the common hall was bound to receive and confirm him in course as the king did the mayor. So he claimed it on Midsummer-day, and said the common hall were to go and elect one sheriff, and to confirm the other that had been declared by him. The hall on the other hand said, that the right of choosing both was in them. The old sheriffs (Pilkington and Shute) put it, according to custom, to a poll; and, it was visible, the much greater number was against the lord mayor. The mayor on this adjourned the court, which, they said, he had no power to do, and went on with the poll. There was no disorder in the whole progress of the matter, if that was not to be called one. But, though the mayor's party carried themselves with great insolence to the other party, yet they showed on this occasion more temperance than could have been expected from so great a body, who thought their rights were now invaded. The mayor upon this resolved to take another poll: and it was resolved that his poll should be that by which the business should be settled: and, though the sheriff's poll exceeded his by many hundreds, yet order was given to return those on the mayor's poll, and that they should be sworn. Box, who was chosen, however, had no mind to serve upon so doubtful an election. So it was necessary to call a new common hall and to proceed to a new election: and then, without any proclamation made as was usual, one in a corner, near the mayor, named Rich, and about thirty more applauded it; those in the hall, that was full of people and of noise, hearing nothing of it. Upon this it was said that Rich was chosen without contradiction, and so North and Rich were returned and sworn sheriffs for the ensuing year.

The court was not even satisfied with thus forcibly depriving the citizens of the appointment of their sheriffs; for, with singular wantonness, they prosecuted Pilkington and Shute, and twelve aldermen and principal citizens of the popular party, for opposing the usurpation of the mayor; and having new juries, as well as judges, at their command, had them condemned in large fines.

One of the earliest victims to this new mode of appointing sheriffs was the illustrious Russel, who observed, in his dying moments on the scaffold, 'that, from the time of electing sheriffs, he concluded the heat in that matter would produce something extraordinary, and was not much surprised to find it fall upon him.'

The livery recovered entirely the right of election, however, at the revolution. Not long after, indeed, Sir John Parsons, who was mayor in 1704, revived the custom of nominating persons for the approbation of the livery, and ever since the election of sheriffs has been thus conducted; but so abundantly qualified is the power now conceded to the mayor, that the exercise of it has become altogether harmless. His lordship usually nominates not fewer than fourteen respectable citizens for the office of sheriffs; but the livery are not bound to approve of one of them, and

have often appointed others of their own selection. Any person being a freeman of London is eligible to the office; and whoever is elected is bound to serve, unless he can swear that he is not worth £15,000. The penalties for refusal are £400, to be paid into the city chamber, and £13 6s. 8d. to the ministers of the city prisons. A citizen, after payment of these fines, is exempted for three years; but an alderman only for one: no person, however, after being once drunk to by the lord mayor, can be drunk to again by any subsequent mayor, unless he becomes an alderman. Whoever serves is obliged to give a bond to the corporation for £1000.

The election of sheriffs takes place annually on Midsummer day, and they come into office at Michaelmas. When chosen, they are sworn into office at Guildhall, and two days afterwards in the court of exchequer at Westminster Hall, a ceremony which, though much ridiculed on account of the supposed test of the sheriff's talents in counting hobnails and chopping of sticks, is solemn and impressive. These services are of feudal origin, and respect the possession of lands in St. Clement's Danes. The usual process now is, when the sheriffs are in attendance at the exchequer to be sworn, the owners of the land are called to do their suit and service, when an officer of the court, in the presence of the senior alderman, produces six horse shoes and sixty-one hobnails, which he counts over in form before the cursitor baron, who on this occasion is the immediate representative of the sovereign. The chopping of sticks originated in a similar manner. The tenants of a manor in Shropshire, held by the city of London, are called upon to do their service, when the senior alderman below the chair steps forward and chops a single stick, in token of its having been customary for the tenants of that manor to supply their lord with fuel. For the duties of the SHERIFF, see that article.

The recorder of the city of London is appointed by the lord mayor and aldermen for life. The qualifications declared in the city books to be essential to the office are, that 'he shall be, as he is wont to be, one of the most skilful and virtuous apprentices of the law of the whole kingdom: a chief man, endued with wisdom, and eminent for eloquence.' He is the first law officer of the city, chief councillor to the magistracy; himself a justice of peace for the city, and one in all commissions of oyer and terminer. When on the bench, he delivers the sentences of the court; he also reads the addresses of the city to the king, and reports to his majesty, after each session of the Old Bailey, the number of persons capitally convicted. In point of rank, he takes the precedence of all aldermen who have not passed the civic chair. A singular instance of the difference in the value of money, and the salaries of public officers, is exhibited in the pay of the recorder. In the reign of Edward I. it was 'only £10 sterling, by the year,' and 'twenty pence for each charter written, and each testament enrolled.' It was afterwards raised to 100 marks, and has since gradually advanced to its present liberal allowance of £2500 a year.

The mayor of the city was originally *chamber*

lain, and the office was held of the crown. In 1204 the right of appointing to the chamberlainship was purchased from the crown; and the office became ever after distinct from that of mayor. The chamberlain ranks next to the recorder in the order of precedence; he is the city treasurer, and receives all the money belonging to the corporation; he has also the charge of all its bonds and securities. The chamberlain is usually selected from such aldermen as have passed the chair. The livery have the appointment of the office; but, though the chamberlain is annually chosen on Midsummer-day, yet he generally continues to hold his situation during life.

The origin of the *common council* has been partly developed in tracing the history of the sheriffs. The custom of summoning certain of the discreeter and wealthier men of each ward, as representatives of the commonalty, which was at first surreptitiously introduced for the purpose of restricting the right of electing the sheriffs, was afterwards continued for better purposes in the establishment of that body, known by the name of the common council. However expedient it might be that the whole body of the citizens should be convened for the election of their principal magistrates, the mayor, sheriffs, chamberlain, &c., and on other extraordinary occasions, for the manifestation of the general will, it was obviously not of equal expedience that they should meet on every matter of ordinary concern. By an act of council of the 6th October, 1692, it was declared, 'that it is, and anciently hath been, the right and privilege of the freemen of the said city, only being householders paying scot and bearing lot, and of none other whatsoever in their several and respective wards, from time to time, as often as there was or should be occasion to nominate aldermen and elect common councilmen for the same respective wards;' but it is not affirmed, for that would have been to affirm what was contrary to the fact, that the right and usage had been the same. Neither is it all householders who have now the privilege of voting for common council-men; for, by act of parliament passed in 1725, it is restricted to those who occupy a house of the annual value of £10.

When the right of electing the common council-men thus reverted to the freemen of the different wards, the rule which the mayors had last observed with respect to the number summoned from each, and which, as we have before seen, had some regard to their relative population, appears to have been adhered to with but few variations. The number is at present fixed at 236 for the whole of the wards; in 1209 it was but thirty-two. Farringdon within, which returns the largest number, has seventeen representatives; Lime Street and Bassishaw but four. The office of common council is annual, and instances of removal are not infrequent. The election for each ward takes place on St. Thomas's day; the alderman as presiding officer, decides on the reception of disputed votes, and declares the return.

The representatives of the wards, being united to the lord mayor and aldermen, constitute what is called the court of common council.

This court has the entire disposal of the funds of the corporation; makes what bye-laws it thinks necessary for the better regulation of its concerns; and possesses the right of nomination to several of the subordinate city offices. It has no stated periods of meeting, but is convened by the lord mayor whenever he sees occasion.

The *common serjeant* is the second law officer in the city, and assists the recorder in all legal questions affecting its interests; he also acts in a judicial capacity, as an assistant to the recorder, to whose office his own is generally probationary. He is usually chosen from one of the city pleaders; but the right of election is vested in the common council, who have sometimes raised to the office individuals who had no connexion with the city. It is the duty of the common serjeant to attend the lord mayor and court of aldermen, both in council and on court days, on all occasions, whether within or without the precincts of the city. To him are committed the general care and management of the orphans' estates until they have passed the lord mayor and court of aldermen.

Common Hall.—In all the earlier charters of the city of London, the freemen are spoken of in a general sense; not, as since distinguished, by the different appellations of freemen, liverymen, and common council-men, but as the 'citizens of London,' 'men of London,' 'the commonalty at large.' Nothing at all is said of councils, or any thing in the shape of a representative body. The only public bodies, on the contrary, which are mentioned in the great confirmatory charter of Henry I., are the court of hustings, composed of the mayor, aldermen, sheriffs, and recorder; and the folk-mote, or folk-meeting, meaning obviously the people in the aggregate.

The usual mode of electing these folk-motes was by the tolling of a great bell, which was hung in a belfry near the east end of St. Paul's church. The name of folk-mote was subsequently changed to that of common-hall; and the right to a vote in it restricted to the livery.

The more usual purposes for which common-halls are now assembled are the election of the lord mayors, sheriffs, and other officers, whose nomination remains with the livery; but they are also frequently convened, in order to take into consideration measures of the government or parliament, affecting the interests of the country or of the city in particular; and still, as of old, the resolutions of the livery of London continue to have a leading influence in giving a tone to national opinion.

The *city companies*, though branches of the general corporation, have each a distinct government, and peculiar liberties and privileges granted to them by their respective charters. Most of them have separate halls for their place of meeting, either to transact business or for their banquets; and each company has a master, wardens, assistants, clerks, and other subordinate officers, for the general management and government of its affairs.

The companies are nearly 100 in number; and their several rights and privileges would fill a volume of ample size; we can only here add, that there are twelve which are called the principal

and sometimes styled honorable, though there are some of the minor order, such as the Stationers' Company, which rival them in real importance. The twelve are, the mercers', grocers', drapers', fishmongers', goldsmiths', skimmers', merchant tailors', haberdashers', salters', ironmongers', vintners', and cloth workers'. The lord mayor elect must always belong to one of these companies; if not at the time of his election, at least before he is sworn into office.

There are no less than forty-nine halls belonging to the incorporated companies of traders and artisans, city of London. Many of these may be found interesting objects to strangers, either for their architecture, or their magnitude, and expression of opulence. Among the best are ironmongers' hall, in Fenchurch Street; merchant tailors' hall, in Threadneedle Street; goldsmiths' hall, in Foster Lane; grocers' hall, Grocers' Hall Court, Poultry; drapers' hall, Throgmorton Street; stationers' hall, Stationers' Court, Ludgate Street; and apothecaries' hall, Blackfriars.

The citizens constituting these societies never forget, in the midst of their abundance, the wants of others. The sums distributed annually to the indigent, by the city companies, from various funds given for the purpose, amount to above £30,000.

ECCLESIASTICAL GOVERNMENT.—In the list of ecclesiastics who formed the second general council held at Arles, in France, in 326, we have the presence of a bishop of London recorded in these terms: 'Ex Provincia Britannie Civitate Londinensi Restitutus Episcopus.' Joceline of Furnes, in his book of British bishops, says, that this Restitutus was the twelfth bishop of London; but little dependence can be placed on the accuracy of his list. In 610 London was, however, anew erected into a bishop's see, and St. Paul's cathedral founded.

Of the bishops who filled this see, till the arrival of the Normans, the only one whose name still lives in the memory of men was the noted St. Dunstan. No less than three churches in and around London have been dedicated to him.

William, the first bishop under the Norman line, was held by the citizens of London in grateful remembrance for many centuries, for his good offices in prevailing with William I. to grant them the ample recognition which he did of their ancient rights and franchises. His remains were interred in St. Paul's cathedral, and a monument erected to his memory by the corporation, on which they inscribed in warm terms the obligations which he had conferred on the city—

Reddita libertas duce
Te; donataq; multis,
Te duce, res fuerat
Publica muneribus.

For a long time the corporation made it one of their principal duties, on lord mayor's day, to do homage at the shrine of this restorer of their liberties.

Gilbert Foliot, who succeeded in 1163 to the bishopric of London, is described as the first English bishop that was ever canonically translated from one see to another.

In 1292 there occurred a remarkable instance of collision between the claims of the bishop of this diocese and the citizens. The bishopric had a manor attached to it, situated in the parish of Stepney, on which there grew 'two faire woods.' Richard de Gravesend, the bishop at that period, wished to enclose these woods for a deer park, and with that view obtained a grant of free warren from the king. The mayor, aldermen, and commonalty, however, would not permit the project to be carried into execution, contending successfully that time, out of memory, 'they had used to take and hunt within the aforesaid woods and without, hares, foxes, conies, and other beasts, where and when they would.'

In 1376 Wickliff was, by the command of the pope, summoned before the archbishop of Canterbury and bishop of London, to answer for the tenets contained in what was called the Lollards' Creed; he appeared before them, accompanied by his friends and protectors, the duke of Lancaster and earl marshal.

The duke is said on this occasion to have threatened to drag the bishop by the hair of the head out of the church; when a crowd of citizens interposed, to protect the latter from the execution of this indecent threat; and the duke and earl marshal were glad to retreat.

At the council of Constance, in 1414, Robert Clifford, bishop of London, and several other eminent ecclesiastics, attended as the representatives of the Church of England. He was one of the thirty cardinals-extraordinary created on that occasion, and was even nominated to the purple on the deposition of the three rival popes of that period, but lost the election, which terminated in favor of cardinal Odo Calonna, pope Martin V.

Henry VIII. gave to this diocese the equally sanguinary Bonner. On the establishment of the reformed religion, under Edward VI., he was displaced by the pious Ridley; but on the restoration of popery, under Mary, the 'high priest of blood, as he had been well named, was reinstated in the see, and Ridley exchanged his mitre for a crown of martyrdom. When Elizabeth came to the throne, Bonner was among the bishops who hastened to tender their allegiance to the new queen, as she was on her way from Hatfield to London; but her majesty, shocked with the recollection of his cruelties, refused to see him. He was degraded from his office and thrown into the Marshalsea, where he perished miserably.

John King, who was promoted to be bishop of London by James I., was remarkable for his eloquence in the pulpit, and hence styled by that facetious monarch the king of preachers. His successor (George Mountain) was of name still happier in a punning age; for it is said to have enabled the king to effect a miracle, by throwing a mountain into the sea. (see)

The next bishops of London were Laud and Juxon.

In the Catholic reign of James II. Henry Compton, bishop of London, was styled, by way of pre-eminence, the Protestant bishop, on account of the noble stand which he made in defence of the rights of the Protestant

church against the encroachments of that prince.

Among the bishops of London, since the restoration, the names of Sherlock, Lowth, and Porteus, have been justly distinguished for those qualities which, in times of domestic peace and tranquillity, do most honor to the clerical character, learning, and piety.

The bishop ranks, in dignity, next to the archbishop of Canterbury and York. The diocese comprehends not only Middlesex, Essex, and part of Hertfordshire, but the British plantations in America. The following parishes in the city are, however, exempt from the bishop's jurisdiction, being peculiar, under the immediate government of the archbishop of Canterbury. viz. Allhallows, Bread Street; Allhallows, Lombard Street; St. Dionis, Back church; St. Dunstan in the East; St. John the Baptist; St. Leonard, Eastcheap; St. Mary Aldermay; St. Mary Bothaw; St. Mary le Bow; St. Michael Royal; St. Pancras, Soper Lane; and St. Vedast, Foster Lane. The chapter consists of the bishop, a dean, a precentor, or chanter, a chancellor, a treasurer, five archdeacons (styled of London, Middlesex, Essex, Colchester, and St. Albans), thirty canons or prebendaries, twelve minor canons, six vicars choral, a sub-dean, and other inferior officers.

The election to the bishopric, in cases of vacancy, is vested in the dean and chapter; but the right is now reduced to a mere matter of form, the person recommended by the king's writ of *congé d'elire* being invariably chosen. The sum at which the see is entered in the king's books is £1000; but it is estimated to be worth, at least, £12,000 per annum.

St. Paul's Cross stood in the midst of the church yard, on the north side towards the east end. Of the period of its erection we have no account; Stowe says, it was of 'unknown antiquity.' The first mention made of it is in 1259, when a folk-mote was assembled at Paul's cross, to hear the complaints that had been made to the king against the mayor and rulers of the city. It appears to have consisted of a hexagonal pulpit of wood, raised upon a flight of stone steps with a leaden canopy surmounted by a large cross. In the picture, in the Society of Antiquaries, mentioned in the preceding article, it is represented as enclosed by a low brick wall, within which there are people taking notes of the sermon. The greater part of the audience sat or stood in the open air: but there were probably, as on the occasion of king James's visit, covered galleries for the accommodation of more distinguished auditors, such as, the members of the royal family, the nobility, the lord mayor and aldermen. At the side of the church there was a covered space, called the shrouds, to which the preacher and congregation both resorted in inclement weather.

The cross was demolished in 1643, by an order of parliament, and was never after restored.

PART V.

COMMERCE, MANUFACTURES, POLICE, &c.

At what period London became celebrated for its commerce is uncertain; Tacitus says, in his

time it was 'a famous mart of foreign and domestic trade;' and, as the Romans were no encouragers of trade; it is not improbable that an active intercourse with the Phenicians, and the Greek colony at Marseilles, might have been carried on by the Londoners long before. With the arrival of the Romans, the foreign commerce of London appears to have fallen, and we have scarcely any record of its existence for some centuries afterwards. In the middle of the fourth century, however, its trade must have become pretty extensive, as 800 vessels were employed in the exportation of corn only.

After the Romans had quitted it, the foreign trade was for some time almost wholly suspended; nor was it until some time after the Norman invasion that it was revived. Fitzstephen, assures us, however, that in his day 'no city in the world exported its merchandise to such a distance.'

Previous to 1268 the Cologne merchants had established themselves in London; and in 1296 a regular commercial company, under the title of merchant adventurers, was incorporated by Edward I. This company, obtaining permission from the duke of Brabant, joined an establishment at Antwerp, where they carried on an extensive manufacture of cloth from wool imported from this country. Edward III., with true national feeling, seeing that England derived but half the advantage from her industry, caused manufactures to be established here, prohibited the exportation of wool, and, producing finer cloths than were to be met with elsewhere, monopolised the principal woollen trade of Europe.

The merchants of London now became too formidable to be kept down by the jealousies of the Genoese and Hanseatic associations, although, in the year 1412, the former had the audacity to seize a quantity of wool and other goods to the value of £24,000, which had been shipped on board several vessels for the Mediterranean. The whole was sold at Genoa; but no sooner was this outrage known than our Henry IV. issued a proclamation, in which he prohibited all commercial intercourse with Genoa until the merchants, to whom he had granted letters of marque, should capture a sufficient number of Genoese vessels to reimburse them the £24,000 they had lost, and £10,000 more for damages.

The commerce of England had long before this period been of sufficient importance to tempt the Jews to settle here in large numbers; and they were treated with a degree of cruelty which marked the illiberal spirit of the age. The Hanse merchants, who had an establishment in London at a very early period, were scarcely less popular, and encountered various persecutions, until they were finally extinguished as a company in the reign of queen Elizabeth.

The spirit of commercial enterprise had, previous to this period, been awakened among the Londoners, and several trading companies formed. One of these, consisting of 240 shareholders, who subscribed a sum of £6000, employed the celebrated navigator, Sebastian Cabot, to superintend the fitting out of three vessels for the purpose of making new discoveries. These ships were the means of opening a maritime in-

tercourse with Russia, and in the succeeding reign the English obtained an exclusive grant of the whole trade of that country. This intercourse led the way to the association of the Muscovy merchants; and several others were afterwards formed, particularly the Eastland Company, the Spanish Company, and the Levant Company; the latter undeceived the grand seignior, who had hitherto considered England a province of France.

That the merchants of London must have been wealthy at this period may be inferred from their fitting out thirty-nine ships, all amply furnished, to repel the threatened invasion of the invincible armada; and at the same time they had 135 ships of 500 tons and upwards engaged in trade. In the following reign, in 1613, we find that the city paid three-fourths of the whole customs of the country. The discoveries of a Drake, a Raleigh, a Hawkins, a Cavendish, and a Frobisher, in the reign of Elizabeth, opened new sources of commerce, which the pacific though inglorious reign of James in some degree improved; and a more active intercourse was also opened with Spain, Portugal, and France. Howe, in his edition of Stowe, enumerates the various countries with which London traded at this period, and the articles imported, adding, that it was 'one of the best governed, most richest, and flourishing cities in Europe, plentifully abounding in free trade and commerce with all nations.'

The reign of our first James was also favorable to commerce; Virginia, the Bermudas, Barbadoes, and Newfoundland, which had become colonies of Britain, opened new markets to the London merchants, and to the honor of the king it must be said, that he gave them every encouragement. He abolished monopolies, which in the preceding reign had been so injurious, and issued a commission for establishing a board of trade, with a view to the extension of commerce and the forming of a better code of navigation laws.

With the increase of foreign trade the naval strength of the country improved. While our commerce was limited to the neighbouring shores of Europe, small vessels were found sufficient; but the discovery of the East and West Indies soon suggested the necessity of having larger ships for long voyages, that would require provisions in proportion to the period it would require to perform them. The Portuguese, who were the first to form European settlements in India, introduced into the trade carracks of 1600 and 1700 tons; and our own East India Company, following the example, built two vessels, the *James* of 1000 tons, and the *Trade's Increase* of 1100 tons, which were larger than any ships at that time employed in the royal navy.

During the early part of the reign of Charles I. peace continued to promote the growth of commerce; and when the necessities of the misguided monarch urged him to make illegal requisitions on his subjects, the London merchants were called upon to fit out seven ships of war, and in addition to this the city, now becoming affluent, afterwards agreed, in 1643, to make a weekly payment of £10,000 for the use of parliament. The establishment of posts, the com-

mencement of price currents, or 'weekly bills of the prices of all commodities in the principal cities of Christendom,' which had long been customary abroad, and the formation of banking houses, are all evidence of the growing commerce of the reign of Charles I. It is true that this monarch afterwards, in revenge for the resistance which the city offered to his arbitrary conduct, endeavoured to destroy what he had assisted to raise, and issued a proclamation, declaring all persons traitors who had any dealings with the citizens; but the decree proved, as might be expected, a dead letter.

The reduction of the rate of interest from ten to eight per cent., in the year 1625, had proved highly beneficial to trade; and Sir Josiah Child relates, that ten years afterwards 'there were more merchants to be found upon 'change, worth each £1000 and upwards, than were formerly, that is, before 1600, to be found worth £100 each.' This rate of interest continued till the year 1651, when Cromwell, who, having firmly established his power, found leisure to apply his mind to civil affairs, and enforce those plans from which the commerce of England drew such great advantages, lowered the interest to six per cent. One of the first measures of the reign of Charles II., on his restoration, was to confirm this act of Cromwell, and with every reduction of interest commerce improved so much that the writer already quoted says, 'Now, since interest has been for twenty years at six per cent., notwithstanding our long civil wars, and the great complaints of the dullness of trade, there are more men to be found on the exchange now worth £10,000 than were then of £1000;' and Sir Josiah adds, 'our customs are much improved, I believe above the proportion of six to one, which is not so much by an advance of the rate of goods as by the increase of the bulk of trade.'

The navigation act, which had been proposed by James I., but was not passed into a law until the protectorate, was also of signal advantage to commerce. Trade rapidly advanced, nor did the great plague, and the equally destructive fire in the following year, do more than give it a temporary check, from which it recovered in a few years, increasing more than ever, until the wars of William III. with France. That our trade was then extensive is evident from the losses it was capable of sustaining, the French having, in the course of two years, captured 3000 sail of trading vessels belonging to this country. So much was commerce depressed during this eight years' war, that the tonnage of the shipping cleared outwards from the port of London was 96,766 tons less in 1696 than it was in 1688; and the value of the merchandise exported had fallen in the same period from £4,086,087 to £2,729,520. The restoration of peace, by the treaty of Ryswick, gave back to London its former trade, which generally formed three-fourths of that of the whole kingdom. In the year 1711 it appears to have been more, the amount of the customs in London being £1,268,995, while those of all the out-ports were only £343,381.

The South Sea bubble, the Scottish rebellion of 1715, and the Spanish war three years after

wards, were all so many checks on the progress of commerce during the reign of George I., and the same may be said of the wars of his successor, and the unhappy struggle in the reign of his late majesty, which terminated in the independence of our flourishing colonies in North America. Commerce, however, can scarcely be said to have suffered by the change; for in the year 1784 the value of the exports to America amounted to £3,397,500. Being nearly £332,000 more than they were in any year previous to the war.

From this period, to the commencement of the revolutionary war with France, the trade of the metropolis increased most rapidly; and the exports, which in 1784 were little more than £3,000,000, were in 1792, £16,762,516 13s. 4d. In commerce there is an elasticity which overcomes all depression; and, although the exports were £2,000,000 less during the first year of the war with France, yet no sooner was the continent embroiled in the contest, than the trade of London was augmented so much, that in the year 1796 the exports were nearly £18,500,000, and the imports nearly £15,000,000. Large as this sum may appear, it has since been more than quadrupled.

During the war our vessels had nearly the whole carrying trade of Europe, and Great Britain became the entrepôt of all the products from beyond sea, destined for the consumption of Europe. Hence our imports in 1811 amounted

to £80,232,767, and our exports to £77,392,056, but on the return of peace, when this country ceased to be the route for the conveyance of foreign productions to continental Europe, the amount of exports and imports became considerably less. Ceasing then to be a channel for distributing the productions of other countries, and of scanty resources for export, Britain depends more than ever for commerce on the skill and ingenuity of her inhabitants in the useful and elegant arts, and in all that can give dignity to trade, and comfort to the people. 'It is on her manufactures,' as an able writer observes, 'that the great commercial importance of the country rests; on that technical talent, possessed by its inhabitants, of working up rude produce; of varying the wrought commodity in every imaginable form; of giving beauty, brilliancy, and durability of color, to every diversity of texture, and combination of material; this labor is the source of all that is enjoyed of elegance and convenience in life.'

It is true that our exports are less than during the war, yet our commerce has assumed a more healthy and a more permanent character. Our foreign trade is increasing in the most satisfactory manner; as also the export of our domestic manufactures. The following official document exhibits the state of our commerce at a recent period:—

Abstract of Accounts of the TRADE and NAVIGATION of the UNITED KINGDOM, during each of the three years ending the 5th of January, 1821, 1822, 1823.

Year.	Value of Imports into the United Kingdom, calculated at the Official rates of Valuation.			Value of Exports from the United Kingdom, calculated at the Official Rates of Valuation.									Value of the Produce and Manufactures of the United Kingdom exported therefrom, according to the real and declared value thereof.		
				Produce and Manufactures of the United Kingdom.			Foreign and Colonial Merchandise.			TOTAL EXPORTS.					
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.
1821	32,438,050	17	3	38,395,555	7	2	10,555,912	10	3	48,951,467	17	5	36,424,652	13	11
1822	30,792,743	4	10	40,831,744	17	5	10,629,689	5	51	461,434	3	1	36,659,681	3	0
1823	30,500,094	17	4	44,236,533	2	4	9,227,589	7	11	53,461,122	9	3	36,968,964	9	9

The actual exports and imports, to and from the port of London alone were many years ago estimated at £70,000,000 sterling annually; and the number of vessels which every year entered the port was not less than 15,000, allowing for the several voyages made by the same vessels. In the foreign trade alone the number employed

was, during the last year, 3587, amounting, in tonnage, to 635,799 tons. The following statement exhibits the relative proportion of the commerce of the port of London with foreign countries, and our own colonies, independent of the coasting trade, which is necessarily immense:—

The NUMBER and TONNAGE of all ships that have arrived during the year 1823, at the port of LONDON, distinguishing British from foreign ships.

Countries.	No. of ships		Tonnage
	Brit.	For.	
France	114	59	18,428
Russia	320	—	66,434
Prussia, Denmark, Norway, and Sweden	144	310	110,744
Holland, Germany, &c.	208	173	51,632
Italy, Sicily, and other places in the Mediterranean	204	1	28,675
Spain, including the Canary Islands	220	15	27,432
Portugal, including the Azores	275	11	27,704
Turkey	50	—	8,187
East Indies	85	—	46,472
China	19	—	25,000
West Indies	419	—	120,682
United States of America	19	40	16,900
South America	55	2	9,944
Canada	225	—	71,505
Cape of Good Hope, Sierra Leone, New S. Wales, &c.	78	—	15,148
Ireland	460	—	42,280
Guernsey, Jersey, &c.	27	—	2,465
Total	2922	611	689,632

London has always been, and must be, from its situation, the centre of British commerce; and although the liberal spirit of the age, in throwing more open the portals of the trade, may bring other ports into competition, yet the London citizen may always exclaim with pride, in the words of Cowper,

Where has commerce such a mart,
So rich, so thronged, so drained, and so supplied,
As London?

The Custom House.—The whole produce of the customs, on the exports and imports of England, were for many years farmed at £20,000. In the year ending the 5th of January, 1823, they amounted to £10,662,847! Such has been the growth of British commerce during a period of less than two centuries and a half. The levying of duties on ships and merchandise is generally attributed to Ethelred, and is said to have been first resorted to by that king in 979, when all vessels trading to London paid certain duties at Billingsgate, or Belin's gate, as it was then called.

The principles upon which the revenue of the customs, which were originally on exports only, were vested in the king were, first, because the king was bound of common right to maintain and keep up the ports and havens, and to protect the merchants from pirates; and, secondly, because he gave the subject leave to depart the kingdom, and to carry his goods along with him.

In 1274 the custom duties were sanctioned, as a source of revenue, by the parliament of Edward I., but the fees must have been very small for more than three centuries afterwards, for in

the year 1590 queen Elizabeth farmed them to one Thomas Smith for £20,000 a year. The queen was induced to do this in consequence of the representations of a person of the name of Caermarthen to her majesty, that she had lost £96,720 3s. 7d. in the customs, during the preceding eight years. Smith, who had been a collector of the customs, well knew their value, for he gained upwards of £10,000 by the contract.

In the year 1613 the customs amounted to £148,075 7s. 8d., of which London alone paid £100,572 18s. 4d. In 1666 they were farmed at £390,000; and in 1692 they amounted to £897,551. During the first half of the last century the customs remained nearly stationary, although commerce had greatly increased. The late reign was one, however, in which great skill and ingenuity were displayed in inventing means to increase the revenue: and although the 'official value of the goods' is still computed, with reference, not to the prices they bear in the current year, but to a standard fixed so long ago as 1696, yet in 1798 a duty of two per cent. was levied on our exports, the value of which was taken, not by the official standard, but by the declaration of the exporting merchants.

The first house for the 'receipt of custom' in London was built in 1385, by John Churchman, one of the sheriffs. This building appears to have been succeeded by another, which was destroyed in the great fire of 1666; a new custom-house on a large scale was erected in 1668, at an expense of £10,000, which was also burnt down by fire in Thames Street, in 1715. Three years afterwards, another custom-house, more spacious in its dimensions, and more regular in its structure, was raised, in which the business was conducted, until a fire which broke out on the morning of the 12th of February, 1814, laid the whole building in ashes, destroying several documents relating to the customs, as well as property to an immense amount. Two poor orphan girls, servants to the house-keeper, perished in the flames, and one man was killed by an explosion of some barrels of gunpowder in the vaults, which occasioned a shock similar to that of an earthquake. Previous to the destruction of the custom-house, which had become very inadequate to the increased business required to be transacted in it, the lords of the treasury had determined on erecting an edifice on a larger scale, and had actually adopted a plan, submitted by Mr. David Laing, the architect, under whose direction the present custom-house was erected.

The new custom-house, which is situated on the banks of the Thames, east of London Bridge, extends in length 489 feet, and in breadth 107 feet; the grand front facing the river, from which it is separated by a terrace, is of Portland stone. The centre is quite plain to the height of the ground floor of the building; but above the windows there is an entablature, divided into two compartments, ornamented with figures in alto relievo. In one compartment the commerce and industry of the country, and the arts and sciences connected with them, are allegorically represented; and in the other the costume and character of the various nations with which we

traffic are delineated. These groups are boldly executed; and, the height of the figures being nearly five feet, they can easily be distinguished from the terrace. Between the entablatures is an inscription recording the date of the erection, surmounted by a large sun-dial, which is sustained by two recumbent figures of Industry and Plenty. Each wing has six columns of the Ionic order; these give a grandeur to the edifice, which, on so extended a scale, might appear as carrying the simplicity of architecture too far. There is one great disadvantage in viewing the custom-house from the terrace, because it is much too narrow to include the whole building in one coup d'œil; and it can only be seen to advantage from the river.

The interior of the building is admirably constructed. There are necessarily several entrances to this noble pile; the two principal ones are in Thames Street. They lead through halls rather commodious than large to the grand staircase, which, by a double flight of steps, leads to lobbies at each end of the long room. This room, which is in the centre, is 190 feet in length, and sixty-six in width; it is divided into three quadrangular compartments by eight piers, surmounted by three domes, through which the rooms are ventilated. In addition to the long room there are upwards of 100 offices, appropriated to distinct branches of the business of the customs, as well as several private rooms. All the passages, lobbies, and the floor of the long room, except where the clerks sit, are of stone groined in brick. They are lighted by vertical lantern lights; and the communication between the most important parts of the house is by iron doors, which slide into a groove in the wall, and are closed at night, when they afford a good barrier against accidental fire. The whole building is well ventilated, and in winter is warmed by means of air-stoves. Several fire-proof rooms have been constructed, into which the books and most valuable papers are every night placed.

The first stone of the new custom-house was laid by the earl of Liverpool, the first lord of the treasury, and the Right Hon. Nicholas Vansittart, chancellor of the exchequer, on the 25th of October, 1813, and completed in 1817. The splendid edifice we have thus described has needed considerable alterations, in consequence of dilapidations in the foundations. The basso-relievo figures have been taken down and the 'long room' has been divided into three distinct apartments.

The business of the customs is under the direction of thirteen commissioners (two of whom fill the offices of chairman and deputy chairman), a secretary, clerks, and a great number of officers.

Connected with the commerce of London, indeed of the whole country, is the noble institution of the *Trinity House*. This society was first incorporated by a royal charter of Henry VIII. the 20th of May, 1514, granting to the shipmen and mariners of the realm authority to erect and establish a guild or fraternity, as well of men as of women, in the parish church of Deptford Strond, in the county of Kent, under the name and title of 'the master, wardens, and assistants of the guild

or fraternity of the most glorious and undivided Trinity.' They were empowered to make laws and statutes among themselves, for the relief, increase, and augmentation of the shipping of England; to levy fines or subsidies on offenders; to acquire lands and tenements to a certain amount; to maintain a chaplain, and to do and perform other acts of piety, and to enjoy all the franchises and privileges shipmen and mariners of the realm have used and enjoyed.

This charter was successively confirmed by Edward VI., queen Mary, and queen Elizabeth. The act of Elizabeth, after confirming to the society the general supervision of the buoys, beacons, and ballastage, enacts, that the corporation of the Trinity House may at their own cost make, erect, and set up any beacons and signs for the sea, on such places of the sea shore, or uplands near the coast, or forelands of the sea, only for sea-marks, as to them shall seem meet. The same act declares it penal to disturb those marks; and further authorises the master of the Trinity house to licence mariners to row on the Thames. By another act, in the 36th of the same reign, the queen granted to the corporation the lastage and ballastage of all vessels upon the river, which was then held by the lord high admiral, lord Howard, who surrendered it for the purpose. Some defects in the preceding patents and acts induced James I. to grant a new charter to the corporation of the Trinity House, giving them more ample powers for their government.

Few chartered companies in the metropolis are of more importance to the commerce and naval power of the country than the corporation of the master and wardens of the Trinity House, to whom is entrusted, in addition to the authority over the beacons and sea-marks, the examination of the masters of the navy, the appointment of pilots for the river Thames, with power to fine, in the penalty of £20, every person who shall act as pilot without their approbation,—the settling the rates of pilotage,—the preventing of aliens from serving on board British ships without their license,—the punishing of seamen in the merchant-service for mutiny or desertion,—the hearing and determining of all complaints of officers and seamen in the merchant-service, subject to an appeal to the high court of admiralty,—the granting of licenses to poor seamen, who are not freemen of the city, to row on the river Thames; and the examination of the mathematical pupils in Christ's Hospital. Such are the duties of this society, which is also charged with the clearing and deepening of the river Thames, in which service sixty barges are employed; and the supplying all ships that require it with ballast.

The revenues of the corporation are dispensed in charity. Independent of their alms-houses, upwards of 3000 decayed seamen, their widows and orphans, are annually relieved by this society, and the alms-houses of the corporation are twenty-eight in number. There are also two hospitals at Deptford belonging to the society.

Its business is transacted in an elegant structure on Great Tower Hill, built of Portland stone. It consists of a rustic basement, but the general order of architecture is Ionic. The

interior displays much good taste and characteristic neatness, particularly the court-room, which is neat and spacious. It was built under the direction of Mr. Samuel Wyatt; the first stone was laid September 12th, 1793, and it was opened for business two years afterwards. The master of the Trinity House is usually one of his majesty's ministers, and not unfrequently the premier.

Breweries.—In no article of general consumption does London maintain so great a monopoly and supremacy as in the brewing of porter, which is not only forwarded to the most remote parts of the kingdom, but exported to our colonies,—to the United States of America, and many of the continental states. So early as the reign of Elizabeth, the consumption of beer must have been very considerable; for in 1580 Sir Thomas Gorges, in applying for the office of gauger, stated to lord treasurer Burleigh that 'there was a deceit to the buyer of beer and ale, both in the assise of the vessels, and in the not filling them up; and that the buyers taken altogether were deceived hereby £30,000 a year.' There is also evidence of the quantity of beer brewed in London, in a calculation made in the year 1585 by order of lord Burleigh. It appears from this account, that there were at that time twenty-six brewers in the metropolis, of whom one-half were stated to be foreigners. They generally brewed six times a week, and the whole quantity brewed in London in one year, in small and strong beer, was 648,960 barrels.

Before we quit the 'olden time,' we may observe that the charge of adulteration, now so frequently made, was also urged against the brewers of the sixteenth century, who are said to have put 'darnel, resin, lime, and chalk, into the ale or beer, which making the drinkers thirsty, they might drink the more;' and that, when hops were dear, 'they put into their drink broom, bay-berries, ivy-berries, and such like things.' It is due, however, to the brewers to say, that these charges were never verified by the surveyors.

Although the excise duties, and the general introduction of tea and coffee, as a substitute for malt liquor at breakfast, must have operated for some time as a drawback on the consumption, yet it seems lately to have received a new impulse. In 1761 the quantity of porter made in London, by fifty-two brewers, was only 975,217 barrels, of thirty-six gallons each; now a single firm, that of Barclay and Co., brews upwards of 330,000 barrels in a year; and the quantity made by the twelve principal breweries has amounted, in one year, to the astonishing number of 1,500,000 barrels. What proportion of this quantity is consumed in London it would be difficult to ascertain.

Some of the principal breweries are among the curiosities of London, which every stranger should see. That known by the name of Whitbread's brewery, in Chiswell Street, the plant of which was a few years ago sold for nearly £1,000,000, was deemed worthy of a royal visit at a time that its business was not so extensive, nor its arrangements so complete, as at present. On the 28th of May, 1787, his late majesty, George III., accompanied by his illustrious con-

sort and the three princesses, and attended by several lords and ladies in waiting, visited this brewery. That of Messrs. Barclay is on an equally magnificent scale. See BREWING.

The ale and small beer breweries, and the distilleries in London, are on a great scale, though inferior to the porter breweries.

The *manufactures* of London are scarcely in proportion to its commerce. In the *silk trade* alone, however, 50,000 persons, or one-sixtieth of the whole population, are said to be employed; and in most of the light manufactures the number is proportionably great. It is no disparagement to the rest of the country, that London excels in its manufactures, since where the best price is paid the best workmen will be attracted; and it is due to the country to say, that to it London is constantly indebted for a succession of artists and mechanics, by whose ingenuity she is not only rendered celebrated but enriched. See SILK.

Many years ago, Sheffield, justly celebrated for its *cutlery*, challenged London to a trial of skill, by sending a knife of a very curious construction to the cutlers' company, with an insertion on one of the blades, defying competition. The London cutlers, ambitious for the honor of their trade, made a pen-knife, containing one well-tempered blade, in which was introduced a piece of straw. On the blade were some lines, stating the fact; and the Sheffield cutlers, who might well feel incredulous, broke the blade, and found the straw entire and unsinged,—a piece of ingenious art for which they acknowledged themselves unable to account; and yet Sheffield was celebrated for its cutlery so far back as the time of Chaucer, whose monk 'a Sheffield whittle bore he in his hose.'

In the more scientific manufactures, such as machinery, optical and mathematical instruments, London has always been celebrated. It was in the metropolis that Mr. Penn made his celebrated burning-glass, of such power, that iron, steel, flint stone, and even the diamond itself, yielded to its almost magic power; and here Dollond carried into effect, if he did not originate, that most important scientific discovery the achromatic glasses; and a Mudge, an Arnold, and a Brockbank, made chronometers, which seem to have approached perfection, as far as it can possibly be attained.

It is highly honorable to the operative mechanics and artists of the metropolis, that amidst all the fluctuation of trade, 'such a thing as a journeyman, tradesman, or any of his family, begging is almost unknown, and may with certainty be pronounced as one of the rarest of contingent events.'

Retail Traders.—A foreigner, in looking over a London Directory, and finding a list of between 30,000 or 40,000 trading firms, will be apt to consider the assertion of Buonaparte, that we are 'a nation of shop-keepers,' true to the letter; and if he is informed that this list, numerous as it seems, does not contain more than one-third of the shopkeepers in the metropolis, he will suspect that there are almost as many sellers as buyers. Still more would a stranger be astonished at learning how lucrative a business shop-

keeping is in London—where a pastry-cook has been known to die worth £100,000, and a dealer in shell fish, who spent the best years of his life in selling oysters in public houses, has left to his heirs a sum of £40,000. Yet such is the case; nor are these solitary instances of success in life. The list of individuals, who have risen from poverty and obscurity to high rank and splendid fortunes, would ‘stretch to the crack o’doom,’ and it is unnecessary to quote instances to show that in London the road to preferment, honor, and fortune, is open to the humblest aspirant.

That such fortunes are amassed in London is the more astonishing, when we consider the great expense with which large establishments are maintained; that the rent and taxes of many a retail trader amount to more than £1000 a year, and that the smallest house, if in a great thoroughfare, will let at the most extravagant rate. A shop, not more than three yards square, with a room above it of the same dimensions, has been known to be let as a snuff shop at a rental of £80 a year, and several other houses equally dear.

Of all the retail traders, the *Haberdashers*, though dealing in such small wares, seem to carry on business to the greatest extent. One single house in the city is known to take, on an average, £1,500,000 sterling a year, or more than 4000 guineas a day—one-half of this vast sum is received in cash for goods sold at the counter, and the other wholesale at a short credit. There are at least two other houses in the same business whose returns are £1000 a day. The proprietor of one of these establishments, which is necessarily large on account of the business being almost wholly retail, always gives the persons in his employment an extra allowance for supper when the receipts of the day amount to £1000; thus expressing his own gratitude, and rewarding and encouraging the exertions of those around him. Nor are haberdashers the only tradesmen who carry on extensive business, or amass large fortunes; there is Exeter Change, long celebrated for its cutlery and hardwares, &c., where the prince of retail dealers, the eccentric Thomas Clark, amassed £1,000,000 sterling, and while he paid £7000 a year to government as income tax, spent only a shilling on his own dinner.

About ten or a dozen years ago a number of establishments somewhat similar to Exeter Change, which is not confined to any one particular branch of trade, sprung up in London, to which the oriental term of bazaar was given, which literally means a market. Of these, only two remain—the western bazaar, in Bond Street, and that of Mr. Trotter, in Soho Square. The latter is a very extensive and well regulated establishment. Several large rooms are fitted up with counters, drawers, shelves, &c., for the sale of almost every species of light articles, where between 500 and 600 females attend and trade on their own account in the various articles of domestic manufacture. The price paid is in proportion to the space occupied. The utmost care is taken that none but persons of the strictest moral character are admitted, and that they shall not be subject to any insult from the idle and dissolute loungers of the other sex.

Two other marts for retail trade have been formed; the Burlington Arcade, in Piccadilly, and the Royal Arcade in Pall Mall; both are elegant architectural improvements, and they have been very successful as commercial speculations.

The streets most celebrated for retail trade are Fleet Street, Ludgate Hill, St. Paul’s churchyard, Cheapside, the Poultry, and Cornhill, in the city; in the Strand, King Street, and Henrietta Street, Covent Garden; Cockspur Street, Pall Mall, St. James’s Street, Piccadilly, Oxford Street, and Bond Street, at the west end of the town. The recent improvement, in opening a communication from Carlton House to the Regent’s Park, has created a new and spacious street for retail business, called Regent Street and the Regent’s quadrant, which has on each side a grand colonade.

Markets and supply of Provisions—Smithfield is the grand mart for the sale of live stock, which is held on Mondays and Fridays. Newgate and Leadenhall markets take the lead for butcher’s meat, poultry, &c., although there are several other markets in various parts of the metropolis, where the business is equally respectable though not so extensive. Covent Garden market is celebrated for the early and abundant supply of fruits, vegetables, herbs, and flowers. The only fish-market in London is that of Billingsgate, which is supposed to have derived its name from Belinus, the son of Dunwallo, who built a gate here, which he ordered to be surmounted with an urn containing his ashes, after his death. It has long been a matter of regret that the sale of fish should be confined to one market, as, owing to the monopoly thus established, the supply of that article is neither so abundant nor so reasonable as it would otherwise be. In the mackerel season, if that fish is very plentiful, the dealers will rather throw their cargo over-board, or sell it for manure, than, by bringing it to town, reduce the price. Salmon, which is often very plentiful, and sold as cheap as at Berwick, or in Yorkshire, and Durham, whence it is supplied, is brought to London packed in ice. Turbot, though caught in great quantities on the Yorkshire coast, and sold there at about 4d. a pound, is always extravagantly dear in London—so dear, indeed, as to render it a luxury attainable only by the wealthy.

The fruits and vegetables consumed in the metropolis are principally produced in the environs; and it is calculated that there are upwards of 6000 acres of ground cultivated as gardens within twelve miles of the metropolis, giving employment to 30,000 persons in winter, and three times that number in summer. It is the opinion of the intelligent author of the *Pomarium Britannicum*, that gardening has conferred a great blessing on the metropolis, in the prevention of pestilential diseases, by making cleanliness a matter of profit, and giving a ready sale and liberal price for the soil, which might otherwise be suffered to accumulate.

Numerous calculations have been made of the annual consumption of food in the metropolis, but this is not easily ascertained, as, although we may know the number of cattle and sheep, yet

we have no means of learning their weight, which, by the modern improvement in feeding, has been considerably increased.

Of the quantity of cattle sold in Smithfield market there are however accurate returns; and we find that, in the year 1822, the numbers were 149,885 beasts, 24,609 calves, 1,507,096 sheep, and 20,020 pigs. But this does not by any means form the total consumed in London, as large quantities of meat in carcases, particularly pork, are almost daily brought from the counties around the metropolis. It would appear that the inhabitants of London have become more partial to mutton than formerly, for the quantity of cattle consumed has not increased in proportion to that of sheep; the quantity of cattle sold at Smithfield in the year 1701, being 88,304, or more than half the number sold in 1822, while the number of sheep was 480,000, or less than a third sold in the latter year. The total value of the cattle sold in Smithfield is calculated at £8,500,000. It is supposed that £1,000,000 a year is expended in fruit and vegetables; the consumption of wheat amounts to 1,000,000 of quarters annually; of this four-fifths are supposed to be made into bread, being a consumption of 64,000,000 of quartern loaves every year in the metropolis alone. Until within the last few years the price of bread was regulated by assize, and it may afford some idea of the vast amount of money paid for this 'staff of life,' when it is stated, that an advance of one farthing on the quartern loaf formed an aggregate increase in expense for this article alone, in London, of upwards of £13,000 a week.

The annual consumption of butter in London amounts to 11,000, and that of cheese to 13,000 tons. The money paid annually for milk is supposed to amount to £1,250,000, although the number of cows kept in the neighbourhood of the metropolis does not exceed 10,000. One grazier at Islington keeps between 600 and 700 cows, and another between 400 and 500.

The quantity of poultry annually consumed in London is supposed to cost between £70,000 and £80,000; that of game depends on the fruitfulness of the season and the kindness of country friends. There is nothing, however, more surprising than the sale of rabbits. One salesman in Leadenhall market, during a considerable portion of the year, is said to sell 14,000 rabbits weekly. The way in which he disposes of them is, by employing between 150 and 200 men and women, who hawk them through the streets.

It appears, from the Northumberland House book, that, in the early part of the sixteenth century, the stores for the household for a whole year were usually purchased at fairs. Far different, however, are the fairs held in the metropolis and its neighbourhood, where

—raree shows are seen, and Punch's feats, And pockets picked in crowds, and various cheats.

Three of these fairs were formerly held in the metropolis, Bartholomew fair, Southwark fair, and May fair; the two latter have been abolished, and the former shorn of much of its ancient

glory. Southwark fair commenced on the 8th of September, on which day the lord mayor and sheriffs were wont to ride in their scarlet gowns, after dinner, at two o'clock, to St. Magnus's church, where they were met by the aldermen. After evening prayer, they all rode through the fair as far as Newington bridge, and then retiring to the bridge house they 'refreshed themselves with a banquet.'

Plays were enacted at St. Bartholemew fair, and Rich is said to have met with Walker, the original Macheath, at this fair, playing in a booth: upon being struck with his talents, he engaged him for the Lincoln's Inn theatre. This fair used to continue for upwards of a week; but in September, 1743 it was limited to three days, on which the proprietors of booths, who usually made a collection for the prisoners in the Marshalsea, declared they could no longer afford it. This so incensed the prisoners, that they pulled up the pavement, and threw stones over the wall on the bowling-green adjoining the prison, by which a child was killed and several persons wounded. The high constables and magistrates now determined on putting down the fair; but proprietors of booths and stalls removed to the Mint, a place that had long claimed peculiar privileges on account of the palace which formerly stood there, built by Charles Brandon, duke of Suffolk. Here the fair was held for some time, until, in the year 1763, it was entirely suppressed.

May Fair, which commenced on the 1st of May and continued for sixteen days, was held near Piccadilly and Park Lane, on the site now occupied by May Fair Chapel and the adjacent mansions, formerly called Brook Fields.

Bartholomew Fair, that annual scene of disorder, is still continued, though reduced in duration from a fortnight, to which it had extended, to three days, the time originally fixed; and it is declining so rapidly that, in a few years, it will probably be discontinued altogether without any positive suppression, as has been the case with the fairs in the environs of London. Indeed some doubts are entertained of the legality of suppressing the fair, as it is held under a charter granted by Henry II. to the priory of Bartholomew, and confirmed by succeeding monarchs.

Two other fairs were held in London, in Tottenham Fields, and at Stepney; but these have been suppressed, as have those of Bow, Edmonton, Brook Green, and West End, all in the immediate neighbourhood of London. There is another fair which, though at some distance from town, claims a notice on account of its popularity with almost all ranks in the metropolis. This is Fairlop fair, which is held on the first Friday of July, in Hainault forest. This fair was founded by Daniel Day, an eminent block-maker in Wapping, who, having an estate in Essex, used to assemble a few friends around him on the 1st of July, under a huge oak in the forest, to dine on beans and bacon. Public curiosity was at length attracted to the spot from this circumstance, and a fair established which, in fine weather, is frequented by thousands from the metropolis.

The Police.—In a large metropolis, such as

London, the subordinate branch of the civil government, the police, is of the utmost importance; and, where this is not well organised, the inhabitants go unprotected, and crimes pass unpunished. In France the police system is supposed to have attained its greatest perfection; but the domiciliary visits and the espionage that are there practised would not be permitted in this country, where it is the proud boast of every man, that 'his house is his castle,' and that 'he cannot be punished but by the laws.'

Of the municipal regulations of the city of London, from the time of Alfred to that of the conquest, historians are not very communicative; but we learn that, when Henry I. had abolished the obnoxious curfew, robbery and murders became frequent in the night. Hoveden, and Walter of Coventry, give us a lamentable picture of the metropolis at a period somewhat later. From these accurate historians we learn that, in 1175, a brother of the earl Ferrers was not only privily slain in London during the night, but that 'it was then a common practice in the city, that 100 or more in a company of young and old would make nightly invasions upon the houses of the wealthy, to the intent to rob them; and, if they found any man stirring in the city within the night, they would presently murder him, in so much that, when night was come, no man durst venture to walk in the streets.' From the same historians we learn that, among the burglars and assassins of this period, there was 'a certain citizen of great consequence, credit, and wealth, surnamed John the Olde, who, when he could not acquit himself by the water ordeal, offered the king 500 marks for his life.'

Intoxication also appears to have been an early vice in the metropolis; for Fitzstephen, a native of London, who was not disposed to slander his fellow citizens, after stating that 'there is no city that hath more approved customs, either in frequenting churches, honoring God's ordinances, observing holidays, giving alms, entertaining strangers, and fulfilling contracts,' adds, 'the only plagues are the intemperate drinking of foolish people, and the frequent fires.'

But, frequent as robbery and other outrages had become in the metropolis, it was not until the year 1253 that the protection of a nightly watch was thought of. To Henry III. we are indebted for this institution, and it was this monarch also who revived an old Saxon law, which is still partially in force, so far as relates to injuries committed by riotous assemblages, 'that if any man chanced to be robbed, or by any means damnified by any thief or robber, he to whom the charge of keeping that county, city, or borough, chiefly appertained, where the robbery was done, should competently restore the loss.'

The pageant or cavalcade of setting the 'marching watch,' in addition to the standing watches was an imposing spectacle. It was dressed 'all in bright harness,' and traversed the principal streets in the city, to the extent of '3200 taylor's yards.' The marching watch amounted to 2000 men; but in course of time it got so relaxed in discipline, and so expensive to the city, that it was abolished by Henry VIII.; and, though afterwards revived by Edward VI., it soon sunk into disuse.

Elizabeth took the advantage of some riots 'to appoint a provost martial, with sufficient authority to apprehend all such as should not be readily reformed and corrected by the ordinary officers of justice; and, then without delay, to be executed upon the gallows, by order of martial law.' Nothing could be more summary than the process of the provost martial, Sir Thomas Welford, who rode through the city with a number of armed men, arrested all vagrants and idle persons, and five of these who were accused of a riot on Tower Hill, were condemned and executed on the spot where they had offended. The martial law of Elizabeth was not long in force, and the police of the metropolis, without undergoing any very violent change, has ever since been improving, until it has attained its present state: which is so far from being considered perfect, that new regulations have very recently been made. The subject has of late years occupied much of the attention of parliament, and, in the session of 1822, a select committee was appointed to enquire into the state of the police of the metropolis.

In the metropolis there are eight police offices, independent of those of guildhall and the mansion-house in the city. At the mansion-house the lord mayor presides; the aldermen attend in rotation at guildhall. In order to the convenience of the magistrates, the city is divided into two districts. All cases which occur eastward of King Street are taken to the lord mayor, and all cases to the westward are referred to the sitting alderman at guildhall. The officers appointed to conduct the business of the police of the city, under the lord mayor and aldermen, are two marshals, at salaries of £500 and £450 a year; six marshal men receiving £130 a year, each; and 1099 patrols, watchmen, constables, &c., the expenses of which, in the year ending 1822, were £28,004 per annum; but, as the returns were not complete, it is probable that it considerably exceeds that sum.

The number of parish constables, patrols, watchmen, &c., in the several parishes in the city of Westminster, and the counties of Middlesex and Surrey, within a circuit of five miles, amounted to 2945 in 1802; and the expense, so far as it was made out in the return to parliament, was £66,700 5s., making the whole number of local police in the metropolis 4044, independent of the horse and foot patrol, and the officers under the direction of the magistrates at the several police offices.

At each of these offices, of which that at Bow Street takes the precedence, there are three magistrates, two clerks, and eight officers, with the exception of the Thames police office, where, instead of the eight officers, there are seventeen surveyors, six land constables, and forty-five river constables, with six river surveyors, and twenty watermen employed above bridge, and at Blackwall.

Under the superintendence of the chief magistrate, at Bow Street, there are the horse patrol, mounted and dismounted; the foot patrol, and a day patrol. The horse patrol was formed in the year 1803, in consequence of the frequency of highway robberies. It is stationed on the principal roads leading to the metropolis, and within

a distance of twenty miles. The foot patrol was established in the time of Sir John Fielding, on account of the great number of footpad robberies: they were originally employed in traversing the principal roads within a distance of four miles from the metropolis; but, in consequence of the great number of street robberies in 1821, it was deemed necessary to confine the exertions of the foot patrol within narrower limits, and to employ them in the streets of the metropolis, while a body of what is called 'the dismounted patrol' was employed in the suburbs. Since that time, an active day patrol has been established, at the suggestion of the parliamentary committee, which has already proved of great service in preventing and detecting the more open depredations committed in this great city.

While we now write (1830) a very efficient police force is organising for the metropolis and suburbs. They are under the superintendence of a military officer, who receives instructions from the Home Department in Whitehall. When we bear in mind the character of our former 'guardians of the night,' and contrast them with the new police establishment, the advantage of the change must at once be obvious. The watchmen were generally decrepid from age and infirmities, while the new police is to be entirely composed of men in the prime of life, and of unblemished character. The cost of the new police establishment will be greater than the old, by about thirty per cent—a circumstance more than compensated by their improved character.

Coaches and sedans.—We read of whirlicotes or open chariots at an early period of ancient history; but the covered coach, which is a luxury of modern invention, was not known in England before the reign of queen Elizabeth.

In 1625 captain Bailey, an old sea officer, first set up coaches to ply for hire, which were hence styled hackney coaches, and not as some have supposed from their having been chiefly employed in conveying the citizens to their villas at Hackney. He began with four, whose customary station was at the Maypole in the Strand, where the new church now stands. The drivers were dressed in elegant liveries, and left in this respect an example which their successors might do well not so entirely to disdain.

In 1635 the number of hackney coaches had so much increased as to be regarded in the light of a nuisance by the court. In that year there was an order passed by the king in the star chamber which proceeds in these terms:—'His majesty, perceiving that of late the great number of hackney coaches was grown a great disturbance to the king, queen, and nobility, through the streets of the said city, so as the common passage thereby was hindered and made dangerous, and the rates and prices of hay and provender and other provisions of the stable thereby made exceeding dear, hath thought fit, with the advice of his privy council, to publish his royal pleasure for reformation therein.' His majesty then commands that 'none should be used therein except they be to travel at the least three miles out of town, and that no person should go in them ex-

cept the owner constantly keep, within the cities or suburbs, four sufficient able horses or geldings fit for his majesty's service, whensoever his occasion shall require them.'

Two years after, however, Charles had so far changed his views that he granted a special commission to the marquis of Hamilton, master of the horse, to license fifty hackney coachmen in and about London and Westminster, with liberty to each to keep twelve, but not more, good horses for the purpose of their business. The number of hackney coaches required at this time would seem, from the number of horses allowed to each coachman, to have been about 300. At present, for the regulating of hackney coaches and chairs in London, there are several statutes, viz.: 9 Ann. c. 23, made perpetual by 3 Geo. I. c. 7, and enlarged as to the number of coaches by 11 Geo. III. c. 24: 42 Geo. III. c. 78, so as to make the whole number to be licensed 1100, and enlarged also as to chairs by 10 Ann. c. 19. and 12 Geo. I. c. 12, making the whole number of those 400. By 48 Geo. III., c. 87, the fares were increased.

By 54 Geo. III., c. 147, 200 hackney chariots were allowed to be licensed as part of the 1100; and, by 55 Geo. III. c. 159, 200 additional hackney chariots were allowed, and several regulations made as to the fares. The other statutes now in force are, 12 Ann. stat. 1, c. 14: 1 Geo. I. c. 57: 30 Geo. II. c. 22 (see CARTS): 4 Geo. III. c. 36: 7 Geo. III. c. 44: 10 Geo. III. c. 44: 11 Geo. III. c. 24, 28: 12 Geo. III. c. 49: 24 Geo. III. stat. 2, c. 27: 26 Geo. III. c. 72: 32 Geo. III. c. 47.

Population.—Until the general census of the population was taken, in 1801, political economists differed widely in their estimates of the number of inhabitants the metropolis contained, and of the progressive ratio of increase. In the year 1377 London is said to have contained about 35,000 inhabitants. Howell, in his *Londinopolis*, says that, when Charles I. wished to ascertain the number of papists and strangers resident in the city, he sent a precept, in 1636—7, to Sir Edward Bromfield, then lord mayor, who caused a census to be taken of the whole population within the city walls, which at that time is said, though erroneously no doubt, to have amounted to 700,000. Howell, having no suspicion of the inaccuracy of this calculation, and inferring that the population had increased one-third, during the twenty years that had elapsed before he published his work—and adding to this the population of the city of Westminster and the suburbs, estimates the whole to amount to 1,500,000 of men, women, and children.

Sir William Petty, whose knowledge of political economy must ever entitle him to respect, formed an equally fallacious opinion as to the increase of population in London. In 1682 he calculated the number of houses at 84,000; and that there were eight persons in each house, which would give a population of 672,000. Sir William expected that London would go on increasing until the year 1800, when he thought the population would amount to 5,359,000 persons!

An historian, who wrote in 1746, calculated

the number of houses at 124,000, and the population at 992,000; but Dr. Brakenbridge, eight years after, fixed it at only 751,812 persons, and there is strong reason to believe that this estimate was nearly correct.

But, to come to more certain data, we find that, according to the census of 1801, London at that time contained 121,229 houses, inhabited by 216,073 families, making 864,845 persons. In 1811 it had increased to 1,099,104; and, in 1831 to 1,474,069 persons. The last census is very minute in its details, and perhaps as accurate as it can well be made. It states that the city of London, within the walls, contains 8002 houses, inhabited by 11,719 families, or 55,778 persons, of whom 27,327 are males, and 28,451 females. Two families are stated to be employed in agriculture; 9609 in trade or manufactures, &c.; and 1960 families not comprised in either of these two classes. Thirty-two houses were building, and 705 uninhabited.

The city without the walls, including the inns of court and chancery, comprises 9232 houses, inhabited by 15,884 families, of whom fifty-five are employed in agriculture, 11,101 in trade, &c., and 4754 families in neither trade nor agriculture. The number of males is 33,413, and of females 34,492, making a total of 67,905.

Forty-nine houses are returned as building, and 426 as uninhabited.

The city and liberties of Westminster contain 20,616 inhabited houses, 864 uninhabited, and 412 building. The population consists of 46,004 families, or 201,842 persons, of whom 95,219 are males, and 106,623 females. Of the families, 119 are engaged in agriculture, 24,092 in trade, and 21,793 in neither the one nor the other.

The borough of Southwark contains a population of 90,000 persons, of whom 43,690 are males, and 46,310 are females. The number of houses inhabited is 12,477; the families 21,207, of whom 272 are employed in agriculture, 15,075 in trade, and 5860 are not comprised in either of these classes. In 1821 there were 208 houses building, and 502 uninhabited.

A considerable portion of the population of the metropolis does not, however, come under any of these divisions, but belongs to what may be called the suburbs in the hundred of Ossulstone, which is classed into four divisions: Finsbury, Mary-le-bone, Lambeth, and the Tower Hamlets. These parts of the town having every year rapidly increased, were admitted, by the provisions of the reform bill, to the rank of separate boroughs, each sending two members to parliament.

LONDON MISSIONARY SOCIETY.—The formation of this religious institution, whose object is the dissemination of Christianity throughout the world, may be dated about the year 1794. The extensive plan of benevolent exertion proposed might have impressed many minds, and occupied many hearts at the same moment; but it is the province of the historian to collect and present to the reader those facts and events which made known to the world the grand design of the projectors, and called the attention of the people at large to the moral necessities of their fellow-beings. In this view the public voice has given to the late Rev. David Bogue, an independent dissenting minister at Gosport, the proud and honorable title of the Founder of the London Missionary Society. Three years before the rise of this institution Mr. Bogue made a vigorous effort to gain attention to this benevolent object; for in a discourse which he preached at Salters' Hall, London, in 1792, before the correspondent board of the society in Scotland, incorporated by royal charter for Propagating Christian Knowledge in the Highlands and Islands, we have a most perfect specimen of a missionary sermon. About this time a conversation with one of his hearers, the widow of his predecessor the Rev. Mr. Williams, was followed up on her part by sending a small sum as her first contribution towards this object, which she pressed him immediately to undertake. The daughter of this lady, who wrote some of the first missionary hymns, used to exult in saying that if Mr. Bogue was the father, Mrs. Williams was the mother of the Missionary Society. But a visit made by Mr. Bogue to Bristol, in

August 1794, to preach at the tabernacle, erected there by the celebrated Whitefield, gave rise to the actual determination to unite the various bodies of Christians in the grand and benevolent scheme. There Mr. Hey, pastor of the independent congregation at Castle Green, Bristol, joined with Mr. Bogue and Mr. Steven, minister of the Scotch church at Covent Garden, London, who was Mr. Bogue's colleague in the tabernacle pulpit at this time, to attempt to rouse the public mind to the neglected duty. In pursuance of this object Mr. Bogue inserted in the Evangelical Magazine for September, 1794, an address to those evangelical Dissenters who practise infant baptism; which produced a powerful effect, and the attention of Christians was kept alive by constant reference to the subject in the same magazine. The associated ministers of Warwickshire, through their organ, Dr. Edward Williams, then minister at Carr's Lane, Birmingham, and afterwards president of the independent college at Rotherham in Yorkshire, were among the first echoes to this awakening voice. Dr. W. had previously made an effort to gain the co-operation of his brethren in the grand cause.

But a meeting had been held in London, at the Dissenters' Library, Red Cross Street, where a conversation took place between the Rev. J. Eyre, of Homerton, and several Scotch ministers in London, Messrs. Waugh, Love, and Steven, on a publication by the Rev. Melville Horne, to rouse attention to missions. Mr. Eyre, on his return from the library, called on the Rev. Matthew Wilks, minister of the Tabernacle, Moorfields, and communicated to him the conversation. These two ministers resolved to meet again

and each to bring a friend with him. Their number having augmented to seven or nine persons, they agreed to meet once a fortnight at the Castle and Falcon in Aldersgate Street, for prayer and reading of the Scriptures on this subject. After several meetings they gave publicity to the affair; addressed Mr. Bogue on the subject, and invited leading men in the several counties of the kingdom to co-operate.

In the month of July 1795 the Evangelical Magazine announced that a meeting would be held in London, in September, to form a missionary society; and a circular letter was extensively dispersed among ministers both in town and country.

On Monday morning, September the 21st, several ministers met at the Castle and Falcon, Aldersgate Street, to make preparatory arrangements. They opened a subscription, amongst themselves, amounting to £740. In the evening a general meeting was held in the same place; at which Sir Egerton Leigh, Bart., presided; and, cordial co-operation being tendered from all quarters, the formation of the society was determined. On Tuesday morning, September 22d, a numerous assembly, including about 200 ministers of different denominations, met at Spa Fields chapel, where Mr. Haweis, rector of Aldwinkle, preached from Mark xvi. 15, 16. After the service a kind of constituent assembly was held in the area of the chapel. Mr. Kingsbury, of Southampton, was chosen moderator, and a committee, consisting of Messrs. Bogue, Eyre, Greathead, Haweis, Hay, Hill, Kingsbury, Lambert, Love, Reynolds, Saltern, Steven, and Waugh, were appointed to bring forward the plan of the new society. In the evening Mr. Burder of Coventry preached in the Scotch church, Crown Court, Covent Garden, from Jonah iii. 2. The next morning Mr. Greathead, of Newport Pagnel, preached at Haberdashers' Hall, on the question 'Who is my neighbour?' In the evening Mr. Hey of Bristol on Ephesians i. 10. On Thursday morning Mr. Rowland Hill preached at Surrey Chapel on Matthew xxi. 14; and the last public service was at Tottenham Court Chapel, on Thursday evening, when Mr. Bogue preached from Haggai i. 2. In the afternoon of Friday, September 25th, the general meeting took place, for the last time, at the Castle and Falcon. The Rev. Mr. Percy having been called to the chair, and the blessing of the Almighty solemnly invoked, Joseph Hardcastle, esq., a merchant of London, was nominated treasurer. The meeting then proceeded to the election of twenty-five directors, and the following gentlemen were unanimously chosen:—The Rev. Messrs. Bogue, Boden, Brooksbank, Burder, Eyre, Greathead, Haweis, Hay, Hill, Lambert, Leigh, Love, Mends, Parsons, Platt, Reynolds, Steven, Waugh, and Wilks; also, Messrs. Foyster, Neal, Stokes, West, John Wilson, and Thomas Wilson. The following gentlemen were afterwards added, with the entire approbation of the society. Rev. Messrs. Audley and Saltern, and Messrs. Alday, Campbell, Cowie, Steven, and Taylor. The Rev. Mr. Love and Mr. Shrubsole were elected secretaries. At the first meeting of the

members of the society it was resolved to recommend and countenance public meetings for prayer, to be held on the evening of the first Monday in every month. This recommendation has been received and practised to a great extent; and to maintain these monthly meetings has become the usage of Christians in almost every part of the British empire, in various parts of the continents of Europe, Asia, Africa, and America, and in many islands of the sea.

The admirable simplicity which characterised the constitution of this society was adapted to render it popular: as its object was to send the gospel to the heathen, and the ultimate end proposed the conversion of the world to God by the diffusion of the truths of Christianity, the code of laws for the regulation of its members and affairs was considered as made by the great head of the church, and contained in the New Testament: it therefore recognised no worldly alliances, it placed the members of the society under no president but him who is head of the church, and anxiously avoided every political and ecclesiastical party in the kingdom, while from the catholicity of its fundamental principles it opened the door and invited the co-operation of the wise and wealthy of every communion.

When such a scheme was proposed it was not only natural but right that persons should hesitate and enquire before they decided, when it is considered how far the different denominations had previously stood from each other, how frequently they spoke of the defects of each other's system, and how warmly they eulogized the excellencies of their own, how little intercourse had existed between them, and how perfectly novel was the experiment of uniting Episcopalians, Presbyterians, Independents, and others, in one active and harmonious society, without acknowledging the peculiarities or superiority of any of them: it is indeed no matter of surprise that such a scheme should to the minds of some have appeared absurd and impracticable; but the experience of the Society has confirmed the reasonable expectations of its projectors, and it has long enrolled upon its lists active and zealous Christians of nearly all communions. As it became generally known, auxiliary societies were formed in different parts of the kingdom, and thus by tributary streams the tide of life flows onward and forward to fertilize the desert and solitary place. After a series of years had elapsed, during which the society had become thoroughly aware of the difficulties which were presented to the success of its labors by the language, manners, and peculiarities of heathen nations, it was determined to establish a seminary or college for the purpose of qualifying young men for the special work of missionaries. At first the directors cheerfully received and sent out those pious men whose zeal constrained them to offer their services to the cause; but time and reflection produced an almost unanimous opinion that a seminary was absolutely requisite for the credit and success of their labors. Gosport was chosen as the appropriate spot whereon to commence this institution; and in selecting the Rev. Dr. Bogue, as the first tutor, the conduct

of the directors was marked by equal wisdom and kindness; his capacious mind, sound judgment, religious heart, and ardent zeal, rendered him eminently valuable in such a station. For nearly thirty years he presided over the seminary; and at his death it was removed to Hoxton, and is now under the superintendence of the Rev. Dr. Henderson, whose labors for the British and Foreign Bible Society, in Russia, form so conspicuous a part of the history of that institution.

The society thus formed, and prepared for useful service, selected the *South Sea Islands* as the first scene of its benevolent labors, amongst a race of people in the most deplorable state of ignorance, and whose beautiful country was filled with habitations of cruelty; subscriptions to a considerable amount were raised for this purpose, a committee of examination formed; and, a number of zealous persons having tendered their services, on the 16th of August, 1796, thirty missionaries, with six women, and three children, embarked from London on board the *Duff*, a vessel purchased by the society for £5000, commanded by captain Wilson. After various delays and disappointments they sailed from England on the 25th of September, and arrived at the harbour of Rio Janeiro: here they refitted, and procured a variety of seeds and plants which it was supposed would be useful for cultivation at Otaheite. The latter part of the voyage was attended with considerable danger. At length, however, on Saturday, the 4th of March, the island of Otaheite was discovered at a considerable distance, and by seven o'clock the next morning they got abreast of the district of Ataboroo. They were received by the inhabitants with astonishment and apparent delight. A solemn service of thanksgiving was performed, at which the natives behaved with great quietness and attention. The *Duff* then proceeded to anchorage in Matavai Bay; and a few days after their arrival captain Wilson obtained an interview with Otto, the king, and stated to him the object for which they had visited his island. A house was now given to the missionaries, and as much land as they thought proper; the next day they went ashore with their beds, chests, &c., and took possession. On the following Sunday the brethren directed the attention of the people to the object of their mission, and Mr. Jefferson addressed them through the medium of an interpreter; some of them enquired whether the messages of God were sent to the servants as well as the king and chiefs. They replied in the affirmative. Otto the king was present on the occasion, but the discourse did not appear to make any impression upon him. The next Sunday Kelso and Harris, who had chosen the islands of Tongatoboo and Christinia, were solemnly set apart to their work at the mission house, and the sacrament of the Lord's supper administered, the bread fruit of Otaheite being used as the symbol of the body of Christ.

The first effort of the brethren was made to prevent the destruction of new born infants, by proposing to take every child that had been born amongst a society called *Arrotes*, where this habit prevailed, into their own care, and provide a

house for the mothers during confinement. They succeeded in some degree. Anxious to impart the blessings of civilisation, the missionaries began early to initiate the Otaheitans in the most useful arts: they therefore constructed a saw-pit, and in the month of April completed the erection of a forge. This caused great astonishment and some fear. Poinarre, the king's son, who was present, was so completely charmed, that he caught the blacksmith in his arms and joined noses with him, as a sign of his highest satisfaction. Captain Wilson having conveyed some of the missionaries to the islands of Tongatoboo and Christinia now returned to Otaheite, and, finding the brethren most hospitably treated, bade them farewell and arrived in England in the beginning of July, 1798.

On receiving the gratifying intelligence of the first successful voyage, the directors, at a special general meeting, resolved to employ a ship belonging to the society in another voyage to the Pacific Ocean, to supply the brethren with assistance in their arduous undertaking; they in consequence sent ten married couples, seven children, and 419 single brethren. On this occasion captain Robson commanded; they embarked in October, and were detained at Portsmouth several weeks by contrary winds; at length on the 20th of December they weighed anchor, and sailed under convoy of the *Amphion* frigate. On the 2d of January, 1799, they lost their convoy, and the following day were alarmed by the appearance of a strange sail; this proved to be an American brig. On the 19th of February when they came in sight of Cape Frio, and expected to anchor in a short time at Rio Janeiro, a strange vessel which had been rapidly approaching fired a gun to bring them to. This shot was soon succeeded by a second; and the result was a communication to the captain of the *Duff*, that his vessel was a prize, and that all her men must instantly quit her, and place themselves at the disposal of the enemy; the vessel in which they were now confined was a French privateer, and they soon learnt that the *Duff* could not be ransomed, as she was to be taken to the Spanish port of Monte Video in South America: a second and third prize captured, they sailed immediately and entered the Rio de Plata on the morning of the 12th of March. Here they met their several families who had been brought thither in the *Duff*. During these detentions they were treated with every possible civility; until a passage was procured for them to Rio Janeiro: whither, after the lapse of a month, they had nearly arrived, when they were doomed to suffer a second capture, owing to the Portuguese vessel in which they sailed, having been purchased without having been regularly condemned. There they suffered considerable hardships, being divided into two parties, those on board the *Amazon* were treated with great humanity, while the brethren on board the *Medusa* were at the mercy of unfeeling and brutal tyrants. After some severe gales, and giving place to several strange vessels, they arrived at Lisbon on the 22nd of September obtained their liberty, and with the exception of one female, who died and was buried there, they all returned to their native land safely.

We now revert to the affairs of Otaheite, where a circumstance had occurred which induced most of the brethren to abandon the scene of their labors. Early in the month of March, 1798, the ship *Nautilus* anchored in the Matavai Bay to undergo repairs and take in water, when two of the seamen and five natives of Owyhee who happened to be on board escaped, and concealed themselves on the shore. The brethren were prevailed upon to send a deputation to the king that the fugitives might be delivered up. On this occasion they were surrounded by about thirty natives, and some of them stripped and maltreated: one narrowly escaped assassination. They however arrived in the evening of the day at the mission house, to the great joy of the brethren who had heard of the outrage: the next day an offering of atonement was presented with a promise to restore the articles of which they had been plundered; eleven of the missionaries, however, conceiving their lives to be in imminent danger, had agreed with captain Bishop of the *Nautilus* to convey them to Port Jackson, whither they arrived after six weeks voyage. Here, however, more severe trials awaited some of them; one was robbed and dangerously wounded, another inhumanly murdered in the vicinity of Sydney. Thus was the aspect of the Otaheitan mission rendered extremely gloomy; but, notwithstanding the departure of their brethren, seven of the missionaries continued at their post.

Twelve new missionaries were sent out in the Royal Post Admiral, a ship with convicts for Port Jackson; during the voyage a putrid fever broke out amongst them, to which about forty persons, including Mr. Taylor the surgeon, and one of the brethren, fell untimely victims; the rest arrived in safety at Otaheite on the 10th of July 1801. In the beginning of the year 1802 the missionaries were able to preach in the language of the country, but at first without apparent effect; on the 3d of September, 1803, Pomarre died almost suddenly, and the death of so powerful a protector excited many apprehensions; they, however, received the assurances of the new king and his mother of every protection. During 1804 and 1805 the missionaries continued to preach the gospel: they also began to form a regular Otaheitan vocabulary, comprising upwards of 2000 words, and applied themselves to the instruction of the native children; the king, who on the demise of his father assumed the name of Pomarre, under the instruction of the missionaries learnt the art of writing, and in 1807 composed a letter to the Missionary Society in London.

The most interesting results followed the labors of the missionaries in this island, notwithstanding the repulsive and discouraging circumstances which attended the commencement of their labors. A rebellion having broken out in Ma'ava, in November 1808, six of the missionaries with their families retired to Huahine in a brig which happened to touch at Otaheite, and the remaining four, Hayward, Nott, Scott, and Wilson, continued with the king; they all, however, excepting Nott and Hayward, subsequently retired to New South Wales; and the mission to the South Sea Islands was to all outward appear-

ance finally given up; but, during their residence in New South Wales, Pomarre wrote repeatedly entreating them to return; which, tranquillity being restored between him and his subjects, they accordingly did. This was the dawn of that bright day, which was to shed the light of Christianity on these benighted people. On their return they found that the king had cast away his idols and observed the Christian sabbath; that he entertained clear views of the gospel; expressed great contrition for his former errors; exerted his influence to convince his relatives of the error of their superstitions, and was extremely anxious to erect an edifice for the worship of the true God. He moreover was very desirous to make his public profession of faith by receiving Christian baptism: this, however, was prudently deferred for some time that he might be more perfectly instructed in the truths of revelation. During the years 1813, 1814, more than fifty nations renounced their idols and desired to be considered as worshippers of Jehovah. Messrs. Nott and Hayward now visited the islands Huahine, Raitea, and Taha, and at the former place a young chief abjured his false gods and professed his faith.

In 1815 the congregation at Gimeo was increased to about 300; conversions to the Christian faith, and the destruction of idols, went on rapidly at Gimeo, Otaheite, Raitea, Huahine, and Tapua Mann, and at the commencement of the year 1818 fifty places of worship had been erected. On the 13th of May, 1818, a general meeting was convened in the district of Papetoia, Eimeo, in imitation of the meeting held in London, when about 2000 of the natives assembled and formed an Otaheitan Auxiliary Missionary Society; shortly after this interesting meeting the brethren, who had recently arrived from England, were conveyed to their several stations in the Windward and Leeward Islands.

The month of May 1819 was a season replete with pleasure at Otaheite; the king had erected a very extensive building at Papara, in the district of Para, and devoted it to the meeting of the Missionary society; it was called the Royal Mission Chapel: it is 712 feet long, and fifty-four wide; the middle is supported by thirty-six massy pillars of the bread fruit tree, and the outside pillars are 280; it has 133 windows with sliding shutters, and twenty-nine doors, the ends are circular; there are three square pulpits about 200 feet distant from each other; it is filled with forms, except an area before each pulpit, and laid with clean grass: the rafters are covered with a fine kind of fringed matting, which is neatly bound with cords of various colors; the whole building is surrounded with a strong fence of wood; the space between it and the building being filled up with gravel. After a preparatory meeting on the 10th, the Royal Chapel was opened on the 11th by three services at the same time; the king was present; the whole congregation stood up and sang. On Thursday the 12th the new laws were publicly promulgated in the centre of this chapel by the king in person, and unanimously approved by the raising up the right hand. On Friday, the 13th, the new Missionary Society met in the chapel:—the king as pre-

sident, and all the governors, officers, and members. On Sunday, the 16th, the congregations assembled again for divine service, and the king was publicly baptised, and received an address entreating him to walk worthy of his high profession. After the service, Pomarre shook hands affectionately with all the missionaries, who were stationed by his desire on his right and left hand; he then returned to his camp.

In May, 1821, the Rev. D. Tyerman and George Bennet esq., were deputed to visit these islands and ascertain the state of the mission; and on the 21st of September they arrived safely at Otaheite. Their report was of the most favorable kind; civilisation, instruction, and translations were all going on admirably: but during their visit king Pomarre was taken ill, and on the 7th of December Mr. Crook one of the brethren was sent for, and arrived in time to speak a few words, witness his departure, and listen to his last words. He reminded the king that Christ was a great Saviour, and could alone support in the article of death. The king replied emphatically, 'Jesus alone,' and sunk into a stupor, which terminated his life in a few hours.

Tongatoboo.—After the first missionaries were landed at Otaheite captain Wilson sailed for the Friendly Isles, and on the 10th of April, 1797, the Duff was moored in the harbour of this island; and on the 12th ten missionaries took up their residence in a house prepared for their reception: here, however, three were murdered by the natives, the remainder departed to Port Jackson in January 1800, and with one exception subsequently arrived in England. After captain Wilson had settled the missionaries at Tongatoboo, in 1797, he sailed for St. Christina one of the Marquesa Islands, with two of the brethren who had chosen it as the scene of labor; one however, disgusted with the people and place, refused to remain, and Mr. Crook a devoted and vilified missionary was left alone to pursue his work in this island. He remained seven months and returned to England in May 1799, thinking that he might render the best service to these islands by representing their real state to the directors.

It may here be worthy of observation that, at the commencement of the operations of the society, the directors expressed their intention of sending the tidings of salvation to the inhabitants of the Sandwich Isles; but the probability of so doing was precluded till the visit of the deputation to the South Seas, where those who had been appointed to a different station were irresistibly led to this scene of usefulness. Mr. Ellis communicated these particulars in his letters to the directors in London: he went to reside there at the earnest invitation of the king and chiefs, as well as some American brethren, who were already settled in this extensive field of labor. This took place in February 1823: in the autumn of the same year the king, Tamahameha, resolved to visit his Britannic majesty, and embarked in November being accompanied by his queen Kamehamara, a chief named Boki and his wife with others. Previously to their introduction to the king, however, both Tamahameha and his consort were seized with the measles,

and died within five days of each other: their bodies received a temporary interment in St Martin's church, but were afterwards conveyed by the Blonde to their native land.

South Africa and its adjacent islands.—Encouraged by their success, in the islands of the Pacific, the London Missionary Society were led to direct their attention in the next place to the continent of Africa; notwithstanding the failure of an attempt in conjunction with other societies to establish a mission in the country of the Foulahs, and the colony of Sierra Leone. The subsequent conquest of the Cape of Good Hope by the arms of his Britannic majesty seemed to present a favorable opportunity of access to the extensive regions of South Africa; but the natural obstructions to their success were very numerous and great. The number of nations and tribes into which the whole population is divided—their perpetual variances and wars—their indolent and wandering habits—the sterility of vast districts—the uncertainty of the climate—and the frequent and long continued droughts, all combined to impede the establishment of Christian churches, and their advancement in civilisation. Much, however, was done in the discovery of what is necessary to be done; and when the number of direct instances of usefulness are collected and brought into one view it will appear very satisfactory and encouraging. Dr. Vanderkemp, the son of a worthy minister of the Dutch church, in Rotterdam, being converted and called to the work of the ministry, was induced to offer his services to the society, and in company with the Rev. Messrs. Hiekerer Edmonds, and Edwards, sailed for the Cape of Good Hope in the month of December, 1798, on board a transport vessel laden with convicts for New South Wales. It was the choice of the brethren to go in this vessel that they might commence their benevolent labors amongst the most miserable and abandoned of their fellow creatures; they were during the voyage exposed to great personal danger from the refractory character of the prisoners; but they became instrumental in doing much spiritual good to these wretched victims of depravity and crime: their lives also were in great jeopardy from a violent storm, but they arrived safely at the Cape and were received with great cordiality. A favorable opening soon occurred to introduce the gospel among the Boschmen, a savage and cruel nation of Hottentots, and Messrs. Hiekerer and Edwards were deputed to this walk, while Dr. Vanderkemp and Mr. Edmonds should pursue their original plan of endeavouring to plant the standard of the cross in Caffraria. Dr. Vanderkemp and his colleague left Cape Town on the 29th of May, and being furnished with letters of recommendation to the landrost proceeded to Graaf Reinet. There they remained a few days, then resumed their journey to the frontier of Caffraria, and after a toilsome and dangerous route reached the residence of Geitha the king, on the 20th of September: after some disputes relative to their continuance the king granted them a tract of land on the other side of the river Keiskamina, and on the 20th of October they took possession. In December, however, not considering themselves safe in Caf-

fraria, the colonists resolved to escape, and Dr. Vanderkemp accompanied them; they arrived on the 14th of May 1801 at Graaf Reinet, where two new missionaries were anxiously awaiting the arrival of Dr. Vanderkemp to whose assistance they had been sent out: here they remained till fresh outrages and internal commotions led them to quit Graaf Reinet in February 1802, and they proceeded with 109 Hottentots under the escort of major Sherlock, to Botsa Place in the vicinity of Algoa Bay, where they had apparently reason to hope for a permanent settlement. But hence also they were obliged to flee, and they removed to Fort Frederick. The Cape being now restored to the Dutch, they waited here till the new government should assign some other spot for their residence; and on a visit from the new governor, in April 1803, he kindly assigned them a tract of land for a settlement about seven miles northward of Fort Frederick in the vicinity of a small river, which the Hottentots call Kooboo.

On their arrival at this new station Dr. Vanderkemp gave it the name of Bethelsdorp, or the village of Bethel: here they planted gardens, erected a temporary church, and houses for their own accommodation; and, in the beginning of July, commenced public worship and opened a school. Their labors were rendered successful in general, and especially in the conversion of Cupido, Boezak, and Sampson: but, in the month of April 1805, in consequence of false representations and unfounded charges made against the missionaries by the Dutch boers, the governor sent for Dr. Vanderkemp, and he and Mr. Read repaired to Cape Town, and were detained there till January 1806, when the British once more took possession of the colony. Sir D. Baird now sent for Dr. Vanderkemp, and treated him with marked respect: he soon afterwards gave the Dr. permission to return by sea to Bethelsdorp, and both himself and Mr. Read were received by their people with every demonstration of joy. In April 1811 Dr. Vanderkemp and Mr. Read were summoned before an extraordinary commission, appointed by the governor at Cape Town; and communicated to the commissioners more than 100 cases of Hottentots said to have been murdered. On the 13th of September five German brethren, with a converted black from Demerara, arrived in safety at the Cape, and were gladly received. They were considering on an arrangement for the disposal of the missionaries, when they were visited with the distressing loss of their venerable and apostolic friend Dr. Vanderkemp, who died on the 15th of December, 1811.

In consequence of this event, and the increasing importance of these stations, the society deputed one of their own body, the Rev. John Campbell of Kingsland, to visit the Cape, where he arrived on the 24th of October, 1812; and, on the 20th of March in the ensuing year, at Bethelsdorp, he found that civilisation had made considerable progress; that the natives exercised the various businesses of smiths, carpenters, sawyers, basket-makers, brush-makers, thatchers, coopers, lime-burners, &c.; he also saw cultivated fields two miles in length, on both sides of a river, and was informed that their cattle had increased

from 218 to 2206. The beneficial effects of Christianity were apparent in this despised spot in a variety of excellent institutions formed by the Hottentots; and they had contributed, during the preceding twelve months, the sum of seventy-six dollars, in aid of the London Missionary Society. When, on his second visit to these parts, Mr. Campbell, with Dr. Philip, called at Bethelsdorp in June 1819, they were much gratified at finding that the Hottentots had erected a substantial place of worship and several good houses. In 1822 and 1823 very considerable improvements were made in the erection of superior habitations: a public store was opened to preclude the necessity of the natives going to distant places to purchase goods; and, in the report communicated to the general meeting in London, in May, 1824, the accounts of their progress in industry and instruction were highly satisfactory.

On the 28th of December, 1823, his majesty's commissioners of enquiry arrived at Bethelsdorp, accompanied by their secretary: they attended divine service at the mission chapel, when Mr. Ketchingman preached from Psalm cxvi. 3. After the sermon about twenty Hottentots read the third chapter of St. John's Gospel, and were examined as to their knowledge of the scriptures: the children read a chapter, and were catechised. The English class then read a few easy lessons; when all was finished the object of the visitors was announced, and some of the old men belonging to the institution rose up to thank the king of England and them, for the interest they took in the poor Hottentots at Bethelsdorp: the honorable commissioners expressed their high satisfaction with the progress of the people, both in civilisation and the knowledge of the truths of Christianity.

Having given this sketch of the proceedings of the missionaries in the colony, near the Cape, we may observe that those beyond it, among the Caffres, Geogiras, Bushmen, Bootchuannas, and Namaquas, and in the African Islands, Madagascar and Mauritius, exhibit great patience and perseverance; an examination of the published accounts of their proceedings and labors will furnish the reader with many instances of gratifying success. The remarkable conversion, the honorable life, and the happy death of the Caffre chief, Africaner; the formation of Christian churches in seven or eight stations within the colony; and the establishment of an auxiliary missionary society at the Cape; are encouraging proofs of the utility and efficiency of such benevolent exertions: they establish, beyond the power of contradiction, that there is not a natural incapacity in the minds of Hottentots for civil, moral, and religious improvement. Much remains to induce deep and painful commiseration, but much may be anticipated to justify the assurance of hope. The other principal settlements in South Africa are Bethany, situated in Great Namaqua Land, about fifty-five miles north of the Orange River, where a mission was commenced in 1815; Steinkopff, in Little Namaqua Land, where the gospel was introduced in 1817; the Pearl, in the district of Stellenbosch, first occupied in 1819; and Cape Town, where a number of heathens attend the ministry of Dr. Phillip.

We next direct the attention of the reader to the labors of the society in *Asia*, including the *East India Islands*, with the extensive country of *China*. In the month of February, 1804, some missionaries sailed from England to commence their work on the coast of Coromandel; they selected Vizagapatam, the capital of one of the five districts into which the northern circars are divided. In 1808 they were joined by a converted brahmin, named Ananderayer, who, in the October following, went on a missionary tour to the southward, and preached the gospel to many hundreds of his countrymen. In 1809 the Rev. George Cran, one of the missionaries, died; and two, Messrs. Gordon and Lee, arrived by way of America, to join Mr. Des Grayes, who by the decease of his coadjutor had been left alone. Mr. Rengletaube, who sailed to India in 1804, selected the Tinivelly country as the scene of labor; but being precluded from going thither till February, 1806, he extended his labors into Travancore, and made that kingdom the principal seat of the mission. After laboring faithfully at this station for several years, ill-health compelled him to relinquish it; in 1816 other persons succeeded him, and in 1818 and 1819 nearly 3000 of the natives placed themselves under religious instruction. In the spring of 1810 the Rev. J. Hands arrived in India with the hope of commencing a mission to Seringapatam; but, as he could not gain access, he was induced to direct his attention to Bellary, in the northern part of the province of Mysore. In 1816 he was joined by Mr. Reeve; many additions were made to the church. In January, 1819, a Juvenile Bible Society was formed in this place; and during the year the gospel was carried several hundred miles through the dark villages, and several thousand tracts were distributed. Messrs Hands and Reeve are advancing with the Canara version of the Old Testament; and Mr. Reeve has undertaken a compilation of a Canarese and English Dictionary. Besides these stations, others have been established in various parts of the East Indies, as at Chinsurah, Madras, Surat, Calcutta, Bangalore, Benares, Belgaum, Quilon, Cuddapat, and Seringapatam.

China.—In order to convey the glad tidings of the Christian salvation to this populous and benighted empire, the London Society resolved to attempt a translation of the Holy Scriptures; the Rev. Robert Morrison was selected for this arduous work, and was assisted in London by a native of China in learning the language and transcribing a harmony of the gospels and other parts of the New Testament from a MS. copy in the British Museum. His attention was also directed to mathematics and astronomy. In the month of January, 1807, Mr. Morrison sailed from England, and arrived in safety at Canton, where he remained till, from a misunderstanding between the European residents at Canton and the Chinese government, all intercourse with foreigners was prohibited. Mr. Morrison, therefore, retired in the beginning of November to Macao, where he applied himself unremittingly to the study of the language. Matters being amicably arranged, our missionary returned to

Canton, and in 1809 was appointed Chinese translator to the English factory. He found the ideas of the Chinese exceedingly obscure with respect to the nature of the true and living God. In September, 1810, Mr. Morrison sent the Acts of the Apostles carefully revised with the Greek text to a Chinese printer, and agreed to pay him 521 dollars for 1000 copies, including the cutting of 30,000 characters, the wood on which they were to be cut, the paper, printing, and binding. When this little work was completed, three ambassadors from the Leki-yo islands, coming to China with tribute, arrived just in time to be presented with some copies. The vernacular tongue of these islands is a dialect of the Chinese language, which is read by the literati. In April, 1812, Mr. Morrison, who had previously forwarded a translation of the Gospel by St. Luke, and a Chinese tract on the way of salvation, now sent a translation of a Chinese edict, declaring the printing of books on the Christian religion in China a capital crime. In the summer of 1814 Mr. Morrison travelled, in the suite of the British embassy, through six provinces of China. This occupied about six months; the embassy arrived at Canton on its return in January, 1817. In September, of the same year, Mr. Morrison says, in a letter to the society, 'I have translated the morning and evening prayers of the church of England, as helps for devotion. The church of Scotland supplied us with a catechism: the congregational churches with a form for Christian assembly. We are of no party; we recognize but two divisions of our fellow-creatures, the righteous and the wicked, those who love our Lord Jesus Christ, and those who do not.' In a letter dated March, 1819, Dr. Morrison observes, that he had recently written a small book, called *A Voyage Round the World*, to this he added a map of the world; but the printer, in copying that part in which Judea was mentioned as the place where Jesus the Saviour was born, obliterated the name of Jesus, probably through fear. In 1820 Dr. Morrison opened at Macao a dispensary for the Chinese sick poor; it became very popular; but, after the return of his family from Europe, our missionary found his time inadequate to its continuance. From the year 1813 the gospel has been more or less regularly preached both in English and Chinese at Macao or Canton; and, besides the advantages derived by European or American residents, these services have not been destitute of beneficial results to some Chinese themselves. In 1823, on the 9th of December, Dr. Morrison embarked for England, where he arrived in safety on the 20th of March; he was presented to the king by the president of the Board of Control, and permitted to lay before his majesty the Chinese version of the Holy Scriptures, made by himself and the late Dr. Milne, and an account of the Anglo-Chinese College at Singapore. His majesty was pleased to convey the expression of his marked approbation. Dr. Morrison had intended to return to China about the latter end of 1824, but consented to remain in England for the purpose of communicating elementary instructions in the Chinese language

and conferring with those who might be desirous of becoming acquainted with it for sacred purposes, or objects of general knowledge and literature.

Malacca.—In the autumn of 1812 the Rev. W. Milne sailed from England to assist Dr. Morrison in his missionary labors in China: he was, however, through the influence of some Catholic priests, obliged to retire from Macao to Canton. He afterwards visited Java, and, having distributed books in great numbers in Batavia, he made a tour through the east of Java and the island of Madura. On his return to China he determined, with the concurrence of Dr. Morrison, to settle at Malacca; accordingly he and Mrs. Milne embarked in April 1815, and, on the 22nd of May, arrived at his destination; he commenced his labors with a charity school for poor Chinese boys, who were instructed in the elementary books common in China, together with writing and arithmetic according to the Chinese method. In January Mr. Milne paid a visit to Penang, or Prince of Wales' Island, and, during his stay, distributed tracts, testaments, &c. On his return to Malacca, in February, he opened two new schools, containing about eighty boys, and introduced the method of writing in sand. In April Mr. Milne distributed some tracts and testaments on board some junks from Siam and Cochin China; in November a Chinese, named Leang Kung Fah, was baptised; in the course of the same month he opened a Thursday evening lecture in the temple Ta-pek-Kung. On the 11th of November, 1818, major Farquhar, commandant of Malacca, laid the foundation stone of an institution called the Anglo-Chinese College, in the presence of the governor of the colony; the chief objects of this institution are the cultivation of Chinese and English literature, and the diffusion of Christianity in the countries and islands eastward of Penang: it owes its origin to Dr. Morrison, who generously devoted the sum of £1000 sterling to the erection of the building, and promised an additional sum of £100 annually, for the first five years, commencing from the opening of the college. This establishment is to be known in future by the name of the Singapore Institution; and in that promising seat of learning the five principal languages of the inhabitants of that part of the globe are to be taught, spoken by not fewer than 300,000,000 of the human race. In March, 1819, Mr. Milne lost his amiable and pious wife; and in 1822, at the beginning of the year, the society sustained the severe loss of his own death. In the month of January, 1819, Mr. Medhurst, who had previously assisted Dr. Milne at Malacca, embarked for Penang; and in 1823 a chapel was erected by subscription for Chinese, Malay, and English worship; the estimated expense was 6000 Spanish dollars: nearly half the sum was raised on the spot, including a donation of 400 dollars from his excellency governor Phillips. The foundation stone was laid on the 11th of June; and, in the course of the summer, the chapel was attended by large and respectable congregations.

Java.—The society, anxious to circulate Dr. Morrison's translations of the Holy Scriptures,

and extend the knowledge of Christianity through the island of Java, the residence of about 100,000 Chinese, sent out missionaries to Batavia, the principal city, and they embarked accordingly on the 31st of December, 1813: these missionaries saw the fruit of the books circulated by Mr. Milne; and here, as well as in the island of Amboyna, prosperity followed their labors. In October, 1819, Mr. Milton removed from Malacca to Singapore, the town and principality of which were originally founded by some adventurers from the island of Sumatra, but which had recently been ceded to the English. Here Mr. Milton established a Christian mission, and his design received the patronage of Sir Stamford Raffles, and W. Farquhar, esq., who gave a piece of land for the object. In 1822 Mr. Thomson removed to this station to take charge of the Malay department, and a place of worship was commenced for services both in the Chinese and Malay languages. In January, 1823, Dr. Morrison visited this station in his way to Malacca, and had several interviews with Sir S. Raffles, who expressed an earnest desire for the removal of the Anglo-Chinese College to Singapore, and that it should be united with a Malayan college to be founded in the settlement, which was eventually done; and the Singapore institution thus formed was to consist of the following departments: 1. A scientific department for the common advantage of the several colleges that may be established; 2. A literary and moral department for the Chinese; and, 3. A literary and moral department for the Siamese, Malay, &c. In the same year Mr. Milton went to Calcutta to purchase presses and other articles for printing; and, on his return, the printing of a Siamese version of Genesis was immediately commenced. About this time the government ordered 200 acres of land to be enclosed for settling and employing such persons as might be desirous of receiving Christian instruction; and directed that converts to Christianity should be admitted to burial in the European cemetery.

The mission to *Demerara* commenced in December, 1807; that to Madagascar in 1818.

A few particulars may be stated respecting each. The success which attended the preaching of the gospel in Demerara, during the year 1808, continued to increase and abound; so that, early in the ensuing spring, the number of slaves admitted into the church by baptism amounted to twenty-four. Mr. Wray had been sent hither at the solicitation of Mr. Post, a respectable and pious Dutch planter, who resided on the east coast of the colony; this excellent man died on the 29th of April, deeply mourned, and deservedly lamented. Mr. Wray says, 'a more affecting scene was perhaps never presented; more than 500 negroes of his own, and from other estates, bitterly lamenting his loss.' Mr. Post secured to the use of this mission the chapel and dwelling house of the minister; and assigned the sum of £100 sterling toward the minister's support, so long as the London Society shall continue to provide a missionary for that station who shall preach the doctrine of the reformed church. On the 25th of May the colonial government issued a proclamation prohibiting

the slaves, under severe penalties, from assembling together before sun-rise or after sun-set; this regulation had an injurious influence in circumscribing the usefulness of the missionary, and Mr. Wray paid a visit to England that a respectful representation of this grievance might be laid before his majesty's government; an official letter was in consequence transmitted to the governor of Demerara, signifying the determination of the government at home that slaves should be allowed to meet every Sunday for worship and instruction, from five in the morning to nine in the evening; and, on other days, from seven to nine in the evening, provided they had permission of their respective masters. This interposition was immediately and readily attended to by the governor, who expressed himself very favorable to the missionaries and their exertions, and it was followed by very salutary effects among the slaves. Mr. Wray, with the consent of the directors, afterwards removed to Berbice; and in January, 1817, Mr. John Smith was sent out by the directors to fill the vacant station, which he continued to occupy, with much usefulness and prosperity, till May 1823, when circumstances arose, of a very painful nature, which have been before the public in all their affecting details, and which led to the termination of his valuable services and life, in the month of February, 1824. The sensation occasioned by this event was communicated to the whole British nation, and it occupied the consideration of the British parliament; and, from the opinions expressed by the leading members of government on that occasion, it is believed the cause of Christian missions will derive important and lasting benefits.

The mission to *Madagascar* was commenced by Bevan and Jones in 1818. They opened a school at Tamatave, and every thing appeared promising and auspicious; but, in the space of a few months, five individuals were carried to an untimely grave, and Mr. Jones, after a partial recovery from the Malagache fever, was compelled to return to the Mauritius. In September, 1820, Mr. Jones returned in company with Mr. Hastie, a gentleman sent by the governor to negotiate with king Radama for the abolition of the slave trade in his dominions. He consented to the proposed treaty, on condition that he should be allowed to send some of his people to the Mauritius and England for instruction, and that artificers should be sent over to him; this request was repeated, and he finally determined to agree in all respects, on condition that Mr. Hastie would take twenty of his subjects for instruction, ten to proceed to Mauritius, and ten to England, and thus a wide door was opened to civilisation and Christianity in Madagascar. His majesty addressed a letter to the directors of the London Missionary Society, to solicit missionaries and artisans; and at the annual meeting in London, in May 1821, the directors and members had the gratification of seeing among them prince Rataffe, the brother-in-law and prime minister of Radama, who had been previously presented to his Britannic majesty at the drawing room. He was attended, on this occasion, by his secretary and interpreter, and four of the youths who

had been sent to England for instruction. These youths were subsequently placed, at the expense of government, in the British and Foreign School, with a view to their learning to read and write the English language. On the 6th of August, in the same year, prince Rataffe, accompanied by the Rev. J. Jefferies and four artisans, sailed to Madagascar. On the 6th of May following they landed at Tamatave, and proceeded, on the 21st, to the interior, where they were received by the king in the most gracious manner, and land was allotted to their use. Of the Malagache youths, one died in England in 1824, leaving behind pleasing evidence of conversion, and three left England for their own country, of whom two were in ill health, which rendered their return indispensable; one was baptised previously to his embarkation; and the remaining three are diligently employed in acquiring a knowledge of their respective trades.

In addition to various stations already noticed the society has sent out laborers to many other parts of the globe: it has devoted missionaries at St. Petersburg and Selinginsk, in Russia; at Corfu and Malta, in the Mediterranean; at George Town, in Demerara; at New Amsterdam, in Berbice; and at the island of Mauritius.

The present state of the missions, considered as a whole, is highly satisfactory. According to the returns received from the South Sea Islands the number of baptised, for the year ending May 1827, was upwards of 300, and the additions to the churches between 300 and 400. Pomare III., and two native distinguished warriors, died during the year, converts to the Christian faith. The gospel by Mark has been printed; also the epistles to the Galatians, Philemon, and Hebrews, and of James and John. The book of Revelation is in the press; the Book of Judges, and the two Books of Samuel, have been revised. Isaiah, the Psalms, and some other epistles, are under revision.

From the islands of Raivavai, Harvey Islands, Marquesas, Friendly Islands, &c., the intelligence is satisfactory and encouraging.

Sandwich Islands.—The mission in this groupe continues to flourish greatly. The labors of the Tahitian teachers are very useful, and meet the approbation of the American missionaries.

New South Wales.—Considerable progress is made in the language of the aborigines; but the great expense, unless aid can be obtained from the local government, renders its continuance doubtful.

ULTRA GANGES. China.—Dr. Morrison has arrived safely at Macao. During his absence Leangafa had composed notes on the Epistle to the Hebrews; an Essay on the true Principles of the World's Salvation; and An Account of Interesting Conversations with his Countrymen.

Malacca.—Native Schools are seven, containing about 250 boys, who make good progress. The number of students in the Anglo-Chinese College, in June 1826, was nearly thirty. *Java* has three Chinese schools. The Chinese, Malayan, and English, services are continued. The subjects of the mission publications are now discussed by the Chinese themselves in the absence of the missionary. *Amboyna*.—Seven native

teachers have been lately sent hence to different islands of the Malayan Archipelago. Mr. Kam's translation of the first volume of Mr. Burder's Village Sermons is in circulation.

EAST INDIES. *Calcutta*.—In the Christian seminary, which has been restricted to the descendants of native Christians, three youths are under instruction, and a speedy addition to their number is expected. In *Bengal* the mission schools make encouraging progress; the stated native services are continued in the towns, and occasional preaching in surrounding villages. Mr. Mundy has composed, in Bengalee, a concise View of the Christian Religion, and a Catechetical Exposition of the Gospel by St. Mark. *Berhampore*.—Here are inveterate prejudices to overcome. There are eight schools; six for boys, containing 280, and two for girls, containing forty. About thirty persons have become converts, and a Christian church has been formed. *Benares*.—Here are four native schools, containing 206 boys, all in a prosperous state: a substantial mission-house has been erected. *Surat*.—Six native schools; boys under instruction about 350. A society has been formed at Bombay called the Bombay Missionary Union; the remaining stations are Madras, Vizagapatam, Conboconum, Cuddapah, Chitoor, Belgaum, Belari, and Bangalore in South Travancore, Nagercoil, and Quilon.

AFRICA.—The Rev. Dr. Phillip still remains in this country. Mr. Miles has visited several missionary stations in the interior, and extended his journey to Caffreland, and the country of Tambookies. Caffraria presents a promising field for missionary enterprise. At Bethelsdorp the amount of subscriptions to the auxiliary society, for the year ending May 1826, was 260 rix dollars. The stations here are numerous:—Paarl, Tulbach, Roscheffeld, Pacaltsdorp, Hankey, Bethelsdorp, Theopolis, Caffraria, Griqua Town, Campbell, Philippolis, Lattakoo, Africamer's Kraal, Bethany, Steinkopf, Pella, and the Islands of Mauritius and Madagascar. In the latter island his majesty Radama continues to take a lively interest in the mission; and the rapidly advancing importance of this station has induced the directors to accept the services of the Rev. J. J. Freeman, late minister of the Gospel at Kidderminster, on the principle of limited service.

WEST INDIES.—At *Demerara* the labors of Mr. Davies, lately deceased, were attended with success: the average attendance at his chapel in George Town was about 400 negroes, the number in church fellowship 130, and in the school 300 adults and 100 children. At *Berbice* the number of adults baptised during 1826 was forty-one; the number in the school, at the close of 1826, was 230, and many have since been admitted. The total number of children in the native schools, in connexion with the several missionary stations, besides numerous adults, is upwards of 12,000.

LONDON, New, a county of Connecticut, in the United States. Its population is 34,107. Its chief towns are New London and Norwich; the former situated on the west bank of the Thames, three miles above its mouth. It has an excel-

lent harbour defended by two forts, and is one of the most commercial towns in Connecticut. It is fifty-four miles east of Newhaven, and 237 north-east by east of Philadelphia.

Also a post town of the United States, in Rockingham county, New Hampshire, containing a respectable and well endowed academy. It is twenty-five miles S. S. E. of Concord, and thirty-five W. S. W. of Portsmouth.

LONDONDERRY, a county of Ireland, is bounded on the south by Tyrone; on the west by Donegal; on the north by the Scottish Sea; and on the east by Antrim, from which it is separated by Lough Neagh, and the river Bann. Its figure is that of an irregular triangle about forty English miles from north to south, and about thirty-one in breadth, including an area of 511,688 English acres, and 798 square miles. It is divided into four baronies, Terkerin, Kenauight, Loughlinsholin, and Coleraine, and thirty-one parishes. About a fourth part of the county is bleak mountains and glens; and even half the remainder is mountainous, a range of mountains running from the northern coast the whole length of the country southwards. But fertile plains and valleys are interspersed between the mountains, composed of rich loams, and gravels, clay, marl, and moor. The mountainous region is diversified by many alpine tracts, interspersed with spots of peat, many of which are reclaimable. There are schistose ridges on the western side of the Roe, near the bed of which marly flats run along almost the whole length of the river. Near Lough Foyle and Lough Neagh they are in general sandy or loamy. These are much occupied as rabbit warrens, which yield, on an average, about 36,000 rabbits annually, the sale of whose skins produces a large revenue. Good pasture has been produced by the burning of the heathy soils in some places; and excellent crops of oats are raised on the low lands, by the same practice. The principal mountains are, in the north, Benyevenagh, which is 1250 feet high; Sawel, towards the south, 1600 feet in height; Benbrodagh, in the centre of the county, 1300 feet in height; Alt English, at some miles distance, of the same height; Slieve Gallen, 1250 feet in height; Donald's hill, 1200 feet.

The system here adopted of letting land on short leases is not calculated to promote agricultural improvement. The arable land is divided and subdivided into the smallest portions, from 250 to a single acre. The great proportion of it is let in parcels containing from three to thirty acres Irish. Potatoes is the principal crop; but on some of the clay grounds wheat is raised, and oats, barley, flax, and rye, occasionally appear. The land is every where destitute of fences, but small plantations are met with in many places. The minerals of this county deserve attention. Basaltic layers, with veins of white lime, clays, zeolite, &c., are found to the east of the river Roe; granite is often found, and in the interior of the county freestone and sandstone; also the beautiful rock crystals, called Irish diamonds. Iron is also in great abundance throughout the county; but the only work ever established for

smelting it was afterwards abandoned. Small quantities of copper and lead have been also found, and coal seems to appear in various parts. The linen manufacture is the staple of the county: and woollen cloth is manufactured at home by the poorer part of the peasantry. The principal rivers are the Foyle or Green River: it is a wide and deep stream; and, after having divided the counties of Tyrone and Donegal, enters this county, a little above the city of Londonderry, and, passing it, expands into the large lake known by the name of Lough Foyle. The Bann, or the White River, flows from Lough Neagh towards the town of Coleraine, four miles below which it meets the sea, over a shallow bar. The Faughan and Roe, which rise in the Cairntogher Mountains, flow into Lough Foyle. Among the streams which join the Bann in its course, or increase the waters of Lough Neagh, is the Mayola. Lough Foyle affords a tolerably good harbour, though there is some difficulty of entering it when a strong wind blows from the west. It is a large oval basin, twelve miles long, and nearly seven broad in the widest part, but it has only one deep channel in the middle, between long banks of sand. The Bann affords a harbour for small vessels up to Coleraine; but Portrush, four miles below it, is generally preferred for vessels of burden. The chief towns, besides Londonderry, are Coleraine, Newton-limavady, Magherafelt, Dungiven, Moynemore, Castle-Dawson, Maghera, Garvagh, Desartmartin, &c.

LONDONDERRY, the capital of the above county, is situated on the west bank of the Foyle, and contains four main streets, which cross at right angles within the walls, and form, with the smaller streets and lanes, a sort of parallelogram, extending 1273 feet by 635. The streets issue from the exchange, and terminate at a gate denominated from them. The ground on which the town stands is hilly and uneven; but great attention has been paid to the paving and lighting of the streets. The old walls, which were built in the year 1614, still remain. On the top of the rampart is a platform covered with a noble parapet. The cathedral is a Gothic structure, built in the year 1633. The tower was lately ornamented, or at least surmounted, with a spire; it has an organ which is esteemed valuable. There are, beside the cathedral, a chapel of ease, two presbyterian meeting houses, and a Roman Catholic chapel. The central market house, or town hall, was built in 1692, over which were the courts of justice; but it has been superseded by a spacious and handsome architectural structure, recently erected for these purposes. The new gaol is esteemed one of the best in the north of Ireland; and the episcopal palace is spacious. Schools for the education of the lower classes have been recently built, and an infirmary has been lately erected on a very large scale. There is a small theatre and linen hall. The chief wharfs and quays, with a good portion of the city, are without the walls. In 1790 a very handsome wooden bridge, upwards of 1000 feet in length, and forty in breadth, was here thrown across the Foyle, a great part of which was thrown down by the ice in 1813. An ex-

tensive commercial intercourse is carried on between Londonderry, the West Indies, and America. The imports are West India produce, hardware, earthenware, flax seed, iron, and timber: the exports yarn, linen, &c. In the harbour there is at all times fourteen fathoms of water.

Both the abbey and town of Londonderry are of great antiquity; and are said to have been burned by the Danes in the year 783. In 1158 it was made an episcopal see; and the cathedral was erected six years afterwards. In 1515 its charter was granted to the London Company. In 1608 it was burned by an Irish chieftain, but the walls were soon re-erected; and in 1641 it was besieged and rescued from the Irish, by whom, however, it was taken in 1649. In 1688 it sustained from the Irish forces, under king James, a siege, which lasted from the month of December 1688 till August 1689; and it was on the eve of being surrendered by the governor, when the inhabitants chose for their governors the Rev. George Walker, an episcopal clergyman, and major Baker. Under these intrepid chiefs the town resisted to the last, and until all the efforts of king James's forces proved abortive. The corporation consists of aldermen, a mayor, twenty-four burgesses, one chamberlain, and two sheriffs. It is 115 miles N. N. W. of Dublin, and fifty-eight W. N. W. of Belfast.

LONDONDERRY (Robert Stewart, marquis of), the second son of the first marquis, was born in the north of Ireland, June 18, 1769, and was educated at Armagh, after which he became a commoner of St. John's college, Cambridge. On leaving the university, he made the tour of Europe, and, on his return, was chosen a member of the Irish parliament. He joined the opposition, in the first place, and declared himself an advocate for parliamentary reform; but, on obtaining a seat in the British parliament, he took his station on the ministerial benches. In 1797, having then become lord Castlereagh, he returned to the Irish parliament, and, the same year, became keeper of the privy seal for that kingdom, and was soon after appointed one of the lords of the treasury. The next year, he was nominated secretary to the lord-lieutenant, and, by his strenuous exertions, and abilities in the art of removing opposition, the union with Ireland was greatly facilitated. In the united parliament, he sat as member for the county of Down, and, in 1802, was made president of the board of control. In 1805, he was appointed secretary of war and the colonies; but, on the death of Mr. Pitt, he retired, until the dissolution of the brief administration of 1806 restored him to the same situation in 1807; and he held his office until the ill-fated expedition to Walcheren, and his duel with his colleague, Mr. Canning, produced his resignation. In 1812, he succeeded the marquis of Wellesley as foreign secretary, and the following year proceeded to the continent, to assist the coalesced powers in negotiating a general peace. His services after the capture of Napoleon, and in the general pacification and arrangements which have been usually designated by the phrase the 'settlement of Europe,' form a part of history. It is suffi-

cient to notice here, that he received the public thanks of parliament, and was honored with the order of the garter. On the death of his father, in April, 1821, he succeeded him in the Irish marquise of Londonderry, but still retained his seat in the British house of commons, where he acted as leader. After the arduous session of 1822, in which his labor was unremitting, his mind was observed to be much shattered; but, unhappily, although his physician was apprised of it, he was suffered to leave London for his seat at North Cray, in Kent, where, in August, 1822, he terminated his life by inflicting a wound in his neck, with a penknife, of which he died almost instantly. This statesman has been censured for a severe, rigid, and persecuting government, and for an undue countenance of despotic encroachment and arrangement as regards the social progress of Europe. His party and supporters, in answer to these strictures, for the most part, plead political necessity and expediency, while no small portion of them defend his views on the ground of principle. He was an active man of business, and a ready, although not an elegant, orator. His remains were interred in Westminster abbey, with great ceremony, but not without an exhibition of popular ill-will.

LONE, *adj.* From **ALONE**. Solitary; **LONELINESS**, *n. s.* } single; unfrequented:
LONELY, *adj.* } loneliness and lonesomeness
LONENESS, *n. s.* } mean solitude; solitary
LONESOME, *adj.* } disposition: lonely, solitary, or addicted to solitude: lonesome, dreary; dismal.

LONG, *adv.* Sax. *gelang*, a fault. By the fault; by the failure. Obsolete, but a 'truly English' word, says Dr. Johnson.

Respective and wary men had rather seek quietly their own, and wish that the world may go well, so it be not *long* of them, than with pains and hazard make themselves advisers for the common good.

Hooker.

LONG, *adj. & adv.* Sax. *long*; **LONGANIMITY**, *n. s.* Gothic, *lung*; **LONG-BUAT**, *n. s.* Fr. *long*; Ital. *longe*; Latin, *longus*. Pro-
LONGEVITY, *n. s.* } tracted; of con-
LONGSOME, *adj.* } siderable length
LONG-SUFFERING, *adj. & n. s.* in space, time,
LONGTAIL, *n. s.* or measure-
LONGWAYS, *adv.* ment; not soon
LONG-WIND'ED, *adj.* terminating or
LONGWISE, *adv.* ceasing; hence
dilatatory, tedious; as an adverb, to a great length; not soon; at a distant point of time; continuously, throughout: longanimity and long-suffering mean forbearance; patience of offence, or suffering: longevity (Lat. *longævus*), length of life: longinuous (Lat. *longinuosus*), long-handed: longimetry, the art of measuring lengths or distances: lonsome, tedious: long-tail, in Shakspeare, 'cut and long-tail,' a cant term for one or another. 'A phrase, I believe, taken from dogs, which, belonging to men not qualified to hunt, had their tails cut.'—Johnson. Longways and longwise, in a longitudinal direction: long-winded, long-breathed; dilatatory; tedious; wordy.

Them among
There sat a man of ripe and perfect age,
Who did them meditate all his life long.

Fuerie Queene.

Some say, that ever 'gainst that season comes,
Wherein our Saviour's birth is celebrated,
The bird of dawning singeth all night long,
And then, they say, no spirit walks abroad.

Shakspeare.

He will maintain you like a gentlewoman.
— Aye, that I will, come cut and longtail under the degree of a squire. *Id. Merry Wives of Windsor.*

They found the war so churlish and lonsome, as they grew then to a resolution, that, as long as England stood in state to succour those countries, they should but consume themselves in an endless war.

Bacon's War with Spain.

With mighty barres of long-enduring brass.

Fairfax.

Doubts and fears are the sharpest passions: through these false optics all that you see is like the evening shadows, disproportionable to the truth, and strangely longer than the true substance. *Sucklin*

He was laid upon two beds, the one joined longwise unto the other, both which he filled with his length.

Hakewill.

Certainly, God is wonderfully gracious, as he is also infinitely just, even to those that will needs incur damnation, having tendered unto them many powerful helps to their repentance; which he hath with much patience and longanimity expected.

Bp. Hall.

That innocent and holy matron had rather go clad in the snowy white robes of meekness and longanimity, than in the purple mantle of blood.

Howel's England's Tears.

These, as a line, their long dimensions drew,
Streaking the ground with sinuous trace. *Milton.*

They open to themselves at length a way
Up hither, under long obedience tried. *Id.*

Long and ceaseless hiss.

But first a long succession must ensue. *Milton.*

It had overcome the patience of Job, as it did the meekness of Moses, and surely had mastered any but the longanimity and lasting sufferance of God.

Browne's Vulgar Errors.

The villainy of this Christian exceeded the persecution of heathens, whose malice was never so longinuous as to reach the soul of their enemies, or to extend into the exile of their elysiums. *Browne.*

We made the trial in a long-necked phial left open at the top.

Boyle.

If the world had been eternal, those would have been found in it, and generally spread long ago, and beyond the memory of all ages.

Tillotson.

And long it was ere he the rest could raise,
Whose heavy eyelids yet were full of night.

Dryden.

The martial Ancus

Furbished the rusty sword again,

Resumed the long-forgotten shield. *Id.*

No man has complained that you have discoursed too long on any subject, for you leave us in an eagerness of learning more.

Id.

They first betray their masters, and then, when they find the vessel sinking, save themselves in the longboat.

L'Estrange.

It may help to put an end to that long-agitated and unreasonable question, whether man's will be free or no?

Locke.

Eldest parents signifies either the eldest men and women that have had children, or those who have longest had issue.

Id.

That those are countries suitable to the nature of man, and convenient to live in, appears from the *longevity* of the natives. *Ray on the Creation.*

Say, that you once were virtuous long ago? *Id.*

A frugal, hardy people. *Philip's Briton.*

This island stands as a vast mole, which lies long-ways, almost in a parallel line to Naples. *Addison on Italy.*

Reduce, my muse, the wandering song; *Id.*

A tale should never be too long. *Prior.*

When chilled by adverse snows and beating rain, We tread with wearied steps the longsome plain. *Id.*

At the first descent on shore, he did countenance the landing in his *longboat*. *Wotton.*

We infer from the mercy and *longsuffering* of God, that they were themselves sufficiently secure of his favour. *Rogers.*

The instances of *longevity* are chiefly amongst the abstemious. *Arbuthnot on Aliments.*

Our two eyes are like two different stations in *longimetry*, by the assistance of which the distance between two objects is measured. *Cheyne's Philosophical Principles.*

A ponderous mace,

Full twenty cubits long, he swings around. *Pope.*

Heaven restores

To thy fond wish the long-expected shores. *Id.*

My smile you minded,

Which, I confess, is too *longwinded*. *Swift.*

Long sentences in a short composition are like large rooms in a little house. *Shenstone.*

Absurd *longevity*! More, more, it cries: More life, more wealth, more trash of every kind. *Young.*

But Beatoun had enjoyed powers too long to be a favourite of the nation. *Robertson's History of Scotland.*

Fain would I hide what I fear to discover,

Yet long, long too well have I known:

All that has caused this wreck in my bosom,

Is Jenny, fair Jonny alone. *Burns.*

Another consequence of such a bill would be a *longer* residence of the bishops in their several dioceses. *Bp. Watson.*

And if we do but watch the hour,

There never yet was human power

Which could evade, if unforgiven,

The patient search and vigil long

Of him who treasures up a wrong. *Byron.*

LONG, *v. n. & adj.* Sax. langian, of Germ.

LONG'ING, *n. s.* } *gelangen*, to ask; beg.—

LONG'INGLY, *adv.* } Skinner, Ex Gal. *loing*,

LONG'LY, *adv.* } i. e. *longinquam*.—Min-

sheu. To desire eagerly or earnestly, taking for or after before the object: as an adjective it signifies desiring; eager. Longly is used for longing by Shakspeare.

And thine eyes shall look and fail with *longing* for them. *Deut. xxviii. 32.*

The great master perceived that Rhodes was the place the Turkish tyrant *longed* after. *Knolles.*

Master, you looked so *longly* on the maid,

Perhaps, you mark not *what's* the pith of all. *Shakspeare.*

Fresh expectation troubled not the land

With any *longed* for change, or better state. *Id.*

I have a woman's *longing*,

An appetite that I am sick withal,

To see great Hector in the woods of peace. *Id.*

If the report be good, it causeth love,

And *longing* hope, and well-assured joy. *Davies.*

When within short time I came to the degree of uncertain wishes, and that those wishes grew to unquiet *longings*, when I would fix my thoughts upon nothing, but that within little varying they should end with Philoclea. *Sidney.*

Praying for him, and casting a *longing* look that way, he saw the galley leave the pursuit. *Id.*

His sons, who seek the tyrant to sustain,

And *long* for arbitrary lords again,

He dooms to death deserved. *Dryden's Æneid.*

To his first bias *longingly* he leans,

And rather would be great by wicked means. *Dryden.*

The will is left to the pursuit of nearer satisfactions, and to the removal of those uneasinesses which it then feels in its want of, and *longings* after them. *Locke.*

There's the tie that binds you;

You *long* to call him father: Marcia's charms

Work in your heart unseen, and plead for Cato. *Addison's Cato.*

Else whence this pleasing hope, this fond desire, This *longing* after immortality? *Id.*

Nicomedes *longing* for herrings, was supplied with fresh ones by his cook, at a great distance from the sea. *Arbuthnot.*

To thee my soul shall pour its prayer,

And ere the dawn has streaked the sky,

To thee direct its *longing* eye. *Merrick's Psalms.*

--then, even then,

I *longed*, and was resolved to speak;

But on my lips they died again,

The accents tremulous and weak,

Until one hour. *Byron.*

LONG (Roger), D. D., a native of Norfolk, was educated at Cambridge; where he became master of Pembroke Hall, and Lowndes professor of astronomy. He was also rector of Cherryhinton in Huntingdonshire, and of Bradwell in Essex; and was author of a Treatise of Astronomy, and the inventor of a very curious astronomical machine, thus described by himself:—'I have, in a room lately built in Pembroke Hall, erected a sphere of eighteen feet diameter, wherein above thirty persons may sit conveniently; the entrance into it is over the south pole by six steps; the frame of the sphere consists of a number of iron meridians, not complete semi-circles, the northern ends of which are screwed to a large round plate of brass, with a hole in the centre of it; through this hole, from a beam in the ceiling, comes the north pole, a round iron rod about three inches long, and supports the upper parts of the sphere to its proper elevation for the latitude of Cambridge; the lower part of the sphere, so much of it as is invisible in England, is cut off; and the lower or southern ends of the meridians, or truncated semi-circles, terminate on, and are screwed down to, a strong circle of oak, of about thirteen feet diameter; which, when the sphere is put into motion, runs upon large rollers of lignum vitæ, in the manner that the tops of some windmills are made to turn round. Upon the iron meridians is fixed a zodiac of tin painted blue, whereon the ecliptic and heliocentric orbits of the planets are drawn, and the constellations and stars traced: the Great and Little Bear and Draco are already painted in their places round the north pole; the rest of the constellations are proposed to follow; the

whole is turned round with a small winch, with as little labor as it takes to wind up a jack, though the weight of the iron, tin, and wooden circle, is about 1000 lbs. When made use of, a planetarium will be placed in the middle. The whole, with the floor, is well supported by a frame of large timber. All the constellations and stars of the northern hemisphere, visible at Cambridge, are painted in their proper places upon plates of iron joined together, which form one concave surface.' Dr. Long published a Commencement Sermon in 1728; and an answer to Dr. Galley's Pamphlet on Greek Accents. He died December 16th 1770, aged ninety-one.

LONG (Edward), the historian of Jamaica, was born at St. Blaize in Cornwall, in 1734, being the son of a gentleman who possessed estates in that island. He was brought up to the law; and on the death of his father, in 1757, proceeded to Jamaica, where he became secretary to Sir Henry Moore his brother-in-law, and lieutenant governor of the island. In 1769 he was obliged to return to England for his health, where he devoted the remainder of his life to literary pursuits, and particularly to the completion of his History of Jamaica, published in 1774, in 3 vols. 4to. In 1797 he resigned his office, and died March 13th, 1813, at the house of his son-in-law, Henry Howard Molyneux, esq., of Arundel Park, Sussex. Mr. Long also wrote a collection of essays, entitled *The Præter*; a novel called *The Antigallican*; *Letters on the Colonies*; and various minor pieces.

LONG (James Le), a French writer of the seventeenth century, born in Paris in 1665. He was a priest of the oratory, and librarian of St. Honore. He published, 1. *Bibliotheca Sacra*, 2 vols. folio, 1723; 2. *Bibliothèque de la France*, folio; 3. *A Historical discourse on Polyglott Bibles*. He died at Paris in 1721.

LONG ISLAND, an island in Penobscot Bay, on the coast of Maine; twelve miles long, and two broad. Also a small island near the coast of Virginia, at the mouth of York River. Long. 76° 35' W., lat. 37° 16' N.

LONG ISLAND, an island belonging to the state of New York, extending east from the city of New York 140 miles. It is not more than ten miles in breadth on a medium, and is separated from Connecticut by Long Island Sound. The island is divided into three counties; King's, Queen's, and Suffolk. Long. 72° to 74° W., lat. 40° 50' N. Population 48,751. Sag-Harbour is the principal port. The south side of the island is flat land, of a light sandy soil, bordered on the sea coast with large tracts of salt meadow. The soil, however, is well calculated for raising grain, especially Indian corn. The north side of the island is hilly, and of a strong soil, adapted to the culture of grain, hay, and fruits, and the eastern part is remarkably adapted to the growth of wood, and supplies, in great part, the city of New York with this article. The principal towns and villages on the island are Brooklyn, Jamaica, Sag-Harbour, Flatbush, Flushing, Setauket, and Huntington.

LONG ISLAND, or HAMOTE, an island on the coast of New Zealand, in Queen Charlotte's Sound, about forty miles long. It has much

wood and large flocks of sea and other fowl, are also seen about the cliffs. Nine miles south of Port Jackson.—Also an island about forty miles with current on the coast of Papua or New Guinea.

LONG ISLAND SOUND, a kind of inland sea, from three to twenty-five miles broad, and about 140 long, extending the whole length of the island, and dividing it from Connecticut. It communicates with the ocean at both ends.

LONGEVITY. Immediately after the creation, when the world was to be peopled by one man and one woman, the ordinary age was 900 and upwards. See ANTEDILUVIANS. Immediately after the flood, when there were three persons to people the world, their age was shortened, and none of those patriarchs, but Shem, arrived at 500. In the second century we find none that reached 240: in the third none but Terah that came to 200 years: the world, at least a part of it, by that time being so well peopled, that they had built cities, and were cantoned out into distant nations. By degrees, as the number of people increased, their longevity dwindled, till it came down to seventy or eighty years; and there it has continued to stand ever since the time of Moses.

That the common duration of man's life has been the same in all ages, since the above period, is plain both from sacred and profane history. Yet instances of lives greatly exceeding that period are not only to be found in the history of all ages and countries, but even in our own country and in the present age. Mr. Whitehurst, in his Enquiry into the Origin and Strata of the Earth, has given a list (since enlarged by Dr. Fothergill) of thirty-two persons, who died between 1635 and 1781, all of whom had lived above a century, most of them considerably longer, and one who was living in 1780 had attained the astonishing age of 175! Lord Bacon assures us, from the most incontestable evidence, that in A. D. 76, when a general taxation was made over the Roman empire, by Vespasian, there were found living in Italy, between the Appennines and the Po, no fewer than 124 persons aged 100 and upwards. Of these fifty-four were 100 years old, fifty-seven were 110, two 125, four 130, four 136, and three 140 years old each; besides nineteen others in Parma, Placentia, Faventia, Rimini, &c., of whom six were 110 years old, seven 120, one 125, two 130, one 131, one 132, and one 150. And, in our own age and country, Sir John Sinclair's Statistical Account affords numerous and authentic evidences, that longevity is far from being uncommon. In proof of this, we might, if room permitted, give quotations from above 400 of the 938 parochial accounts in that work; but we shall content ourselves with only one from that of Crossmichael in Galloway:—'Within these twenty years,' says the Rev. J. Johnstone, 'at least twelve persons have died in the lower parts of Galloway, from 100 to 115 years old. William Marshal, a tinker in this place, is now 118. He might pass for sixty. His faculties are unimpaired, and he walks through the country with ease.' From the various instances of longevity given by Mr. Whitehurst and others, we shall only select a few of the most remarkable.

Names.	Ages.	Places of birth or abode.	Living or dead about
Hippocrates	104	Isle of Coos	358 A. A. C.

LONGFORD, an inland county in the province of Leinster, and kingdom of Ireland, bounded on the north by the counties of Leitrim and Cavan: on the south and east by Westmeath county: and on the west by Roscommon. It extends about twenty-six miles in length, and measures about twenty-four in breadth. Its superficial contents are 134,152 acres, which are subdivided into twenty-three parishes, and six baronies, the latter called Longford, Granard, Ardagh, Moydoe, Rathcline, and Abbeyshruel. Longford is rather a level country, much intermixed with bog, the northern angle alone being occupied by hills, which are bleak and barren. In the townland of Lisardowling is a small hill or moat called the centre of Ireland.

The chief rivers are, the Shannon, which forms its western boundary, the Inny, the Camlin, and the Faller; the swellings of these, besides the inundations of Lough Gawnagh, lay great parts of the country occasionally under water, and considerably obstruct tillage. The articles of manufacture produced here are yarn, and good brown

linen; and the agricultural export consists chiefly of oats. The chief towns are Longford, Granard, Lawsborough, Johnstown, and Edgeworthstown, near which is the residence of that elegant and moral writer, Miss Edgeworth. Longford formed part of the ancient district of Annaly or Angalia, the country of the O'Ferrals, who were dispossessed by the English settlers, the Delamares, and Tuites.

LONGFORD, the chief or assizes town of the county of the same name in Ireland, is situated on the river Camlin, in the barony of Longford, at the distance of about seventy English miles from the city of Dublin. It is a market, post, and fair town, consisting of one principal street, with a market-house, new gaol, court house, infirmary, diocesan school, permanent barrack, a good inn, and brewery. The situation is flat, exposed, marshy, and unhealthy; the only elevated ground in the vicinity is the hill of Fenagh-fadd, which rises to a height of about 200 feet only. The trade of this little town, as well as the salubrity of its climate, would derive material

benefit, by a branch from hence to the canal at Killashee, only four miles distant. The family of Pakenham derive the title of earls from this place.

LONGING is a preternatural appetite in pregnant women, and in some sick persons when about to recover. It is called *pica*, from the bird of that name, which is said to be subject to the same disorder. It consists of a desire of unusual things to eat and drink, and in being soon tired of one and wanting another. It is called *malacia*, from *μαλακος*, weakness. Chlorotic girls, and men who labor under suppressed hemorrhoids, are very subject to this complaint, and are relieved by promoting the respective evacuations. In general, whether this disorder is observed in pregnant women, in persons recovering from an acute fever, or in those who labor under obstructions of the natural evacuations, this craving of the appetite should be moderately indulged.

LONGINUS (Dionysius), a celebrated Greek critic of the third century, by some said to have been born in Athens, by others in Syria. His father's name is unknown, but by his mother he was allied to the celebrated Plutarch. His youth was spent in travelling with his parents, which afforded him an opportunity of collecting knowledge, and of improving his taste. After his travels, he fixed his residence at Athens, and with the greatest assiduity applied to study. Here he published his Treatise on the Sublime; which raised his reputation to such a height, and gave the Athenians such an opinion of his judgment and taste, that every work was received or rejected by the public, according to his decisions.

He seems to have staid in Athens a long time; here he taught the academic philosophy, and among others had the famous Porphyry for his pupil. But it was at length his fortune to be drawn from Athens, and to mix in more active scenes; to train up young princes to virtue and glory; to guide the busy passions of the great to noble objects; and at last to die in the cause of liberty. Zenobia, queen of the east, prevailed on him to take the education of her sons; and he soon gained a great share in her esteem. That princess was at war with Aurelian: and being defeated by him near Antioch, was compelled to shut herself up in Palmyra, her capital city. The emperor wrote her a letter, in which he ordered her to surrender; to which she returned an answer, drawn up by Longinus, which filled him with resentment. The emperor laid siege to the city; and the Palmyrians were at length obliged to surrender. The queen and Longinus endeavoured to fly into Persia; but were overtaken and made prisoners when on the point of crossing the Euphrates. The queen, intimidated, weakly laid the blame of vindicating the liberty of her country on its true author; and the brave Longinus, to the disgrace of the conqueror, was immediately executed. The writings of Longinus were numerous, some on philosophical, but the greater part on critical subjects. Dr. Pearce has collected the titles of twenty-five treatises, none of which have escaped the depredations of time and barbarians. The best edition of his works is that of Tollius, printed at Utrecht, in 1694, cum notis variorum. It has been translated into English by Mr. Smith.

LONGITUDE.

LONGITUDE, *n. s.* 2. Fr. *longitude*; Lat.

LONGITUDINAL, *adj.* *Longitudo*. Length; the greatest dimension; the earth's circumference measured from a given meridian; the distance of any part of the earth east or west of any other given place.

To conclude;
Of *longitudes*, what other way have we,
But to mark when and where the dark eclipses be?

Donne.

The ancients did determine the *longitude* of all rooms, which were longer than broad, by the double of their latitude.

Wotton.

Some of Magellannus's company were the first that did compass the world through all the degrees of *longitude*.

Abbot.

The *longitude* of a star is its distance from the first point of numeration towards the east, which first point, unto the ancients, was the vernal equinox.

Brown's Vulgar Errors.

His was the method of discovering the *longitude* by bomb-vessels.

Arbuthnot and Pope's Martin Scriblerius.

The variety of the alphabet was in mere *longitude* only, but the thousand parts of our bodies may be diversified by situation in all the dimensions of solid bodies; which multiplies all over and over again, and overwhelms the fancy in a new abyss of unfathomable number.

Bentley.

Longitudinal is opposed to transverse; these vesti-

culæ are distended, and their *longitudinal* diameters straightened, and so the length of the whole muscle shortened.

Cheque.

LONGITUDE, in geography and navigation, is the angle at the pole, included between the meridian of any place, and the first meridian; and it is generally measured on the equator; though, considered in itself, it may with equal propriety be measured on any parallel of latitude; but, when difference of latitude and difference of longitude are to be composed, it is expedient that they should be estimated on circles of equal radii, therefore in navigation longitude is measured on the equator. See **NAVIGATION**.

The method of finding the longitude is a problem of such importance and such difficulty, and has occupied so large a space in the application of science to the business of practical life, that an account of the circumstances which have contributed to bring its solution to the state in which we now have it, cannot fail to be in a high degree interesting. We shall therefore give a brief sketch of the various methods which have been proposed for discovering it, the principles on which they depend, with directions for putting in practice such of them as have been found useful, and illustrate the whole with appropriate examples.

HISTORY OF THE ATTEMPTS WHICH HAVE BEEN MADE TO DISCOVER THE LONGITUDE AT SEA.

No sooner had navigators ventured out of sight of land, than the importance of some method of finding the longitude as well as the latitude by observation began to be felt. In 1598 Philip III. of Spain offered a reward of 1000 crowns to any one who could give a solution adequate to the wants of seamen; and soon after the states general offered a reward of 10,000 florins. The British parliament passed an act in 1714, empowering certain commissioners to make such experiments as they might deem necessary to facilitate the solution of this problem, and assigned £2000 to defray any expenses that might attend the experiments: and further granting a reward to the person who might make any progress in the solution, proportionable to the degree of accuracy which might arise by the solution in practice; £10,000, £15,000, and £20,000, being the rewards offered, if the proposed solution should be capable of determining the longitude to a degree of a great circle, two-thirds of a degree, or half a degree respectively.

The improvements in nautical science which the preceding munificent rewards induced philosophers, mathematicians, and artists, to labor at accomplishing, having ultimately been so far successful, that the highest reward was adjudged to one individual; it was represented to parliament, in 1818, that the longitude could now be by at least two separate methods be found at sea within the limits which had been previously specified, a new act was passed empowering the commissioners for the discovery of the longitude to propose from time to time to his majesty in council, to establish three scales of proportionate rewards to be paid to any one who shall by any principle not yet made public, ascertain the longitude within three new corresponding scales of limit and condition, those rewards not respectively exceeding £5000, £7500, and £10,000; and giving also to the board of longitude very liberal powers to reward any discovery tending to benefit navigation; and finally permitting the board to recompense any person who may propose or contrive any thing ingenious in itself and useful in science, and which may deserve encouragement, even though the results which it furnishes may not come within the limits of that exactness to which his majesty may be recommended, to adhere in adjudging the preceding rewards.

Encouraged by such offers, the talent which has been employed on this problem is not to be wondered at. In 1635 John Morin, professor of mathematics at Paris, proposed a method of solving it to cardinal Richelieu; and though, from the then imperfect state of the lunar tables, the commissioners employed to examine this method judged it insufficient, Cardinal Mazarin in 1645 procured a pension of 2000 livres for the author.

The many attempts that have been made at the solution of this problem may all be said to depend on the same principle, the determining the difference of time between two meridians; for this time is the same part of twenty four hours, that the angle included between those meridians is of four right angles. Hence one hour of difference

in time corresponds to a difference of 15° of longitude.

The time at the place of observation can generally be obtained with great ease and exactness, so that the chief difficulty in the solution of this problem lies in finding the time at the first meridian.

Gemma Frisius in 1530 seems first to have suggested the method of finding the longitude at sea by means of watches or time keepers, which machines he says were then but lately invented.

Such a machine being regulated, to Greenwich time, for example, would always show the time of day at Greenwich wherever it might be carried to, and the difference between this time and that at the place found by observation would give, as we have shown above, the longitude of the place from Greenwich.

The same method was soon after attempted by Metius, and some others, but the art of watch-making was at that time too imperfect to enable them to succeed. Dr. Hook and Mr. Huygens, about the year 1664, applied the pendulum spring to watches which were employed for the purpose of discovering the longitude at sea. Dr. Hooke's indeed, from his having quarrelled with the ministry, were never put on trial at sea, but many experiments were made with those constructed by Huygens. Major Holmes in particular, in a voyage from the coast of Guinea in 1665, predicted, by the aid of one of these watches, the longitude of the island of Fuego to a considerable degree of accuracy. Experience however soon convinced Huygens that unless some method could be found of correcting the irregularities caused in the going of these watches by the effects of heat and cold, they could be but of little practical use in finding the longitude.

A method of finding the longitude was proposed by Whiston and Ditton, which, though perfectly useless for determining the longitude at sea, has been successfully practised for finding it on land. In the improved method of putting it in practice, rockets are fired perpendicularly at some intermediate place between those whose difference of longitude it is proposed to determine, and the time at each place, when the rocket is seen to explode in the air, being noted, the difference of those times gives the element required. The relative situations with respect to longitude, of some of the observatories on the continent, have been determined by this method, and very recently a series of experiments of this kind have been successfully concluded for determining the difference of longitude between the observatories of Greenwich and Paris.

In 1714 Henry Sully, an Englishman, printed a small tract at Vienna, upon the subject of watch-making. Having afterwards removed to Paris, he applied himself to the improvement of time-keepers for the discovery of the longitude. He taught the famous Julian de Roy; and this gentleman, with his son, and M. Berthoud, are the only persons, who, since the days of Sully, have turned their thoughts this way. But, though experiments were made at sea with some of their watches, they were not able to accomplish any thing of importance with regard to the principal point. SEE CLOCK-MAKING.

The first who succeeded in any considerable degree was Mr. John Harrison; who, in 1726 produced a watch which went so exactly, that for ten years together it did not err above one-second in a month. In 1736 it was tried in a voyage to Lisbon and back again, on board one of his majesty's ships; during which it corrected an error of a degree and a half in the computation of the ship's reckoning. In consequence of this he received public encouragement to go on; and, by the year 1761, had finished three time-keepers, each of them more accurate than the former. See HARRISON.

The last turned out so much to his satisfaction that he now applied to the commissioners of longitude for leave to make an experiment with his watch in a voyage to the West Indies. Permission being granted his son Mr. William Harrison to set out in his majesty's ship the *Deptford* for Jamaica in the month of November 1761, this trial was attended with all imaginable success. The longitude of the island, as determined by the time-keeper, differed from that found by astronomical observations only one minute and a quarter of the equator; the longitude of places seen by the way being also determined with great exactness. On the ship's return to England, it was found to have erred no more during the whole voyage than $1^{\circ} 54\frac{1}{2}''$ in time, little more than twenty-eight miles in distance; which being within the limits prescribed by the act, the inventor claimed the £20,000 offered by government. Objections, however, were started. Doubts were pretended about the real longitude of Jamaica, as well as the manner in which the time had been found both there and at Portsmouth. It was alleged also that although the time-keeper happened to be right at Jamaica, and after its return to England, this was by no means a proof that it had always been so in the intermediate times; in consequence of which allegations another trial was appointed in a voyage to Barbadoes.

Precautions were now taken to obviate as many of these objections as possible. The commissioners sent out proper persons to make astronomical observations at that island; which, when compared with others in England, would ascertain beyond a doubt its true situation. In 1764, then, Mr. Harrison junior set sail for Barbadoes; and the result of the experiment was, that the difference of longitude betwixt Portsmouth and Barbadoes, was shown by the time-keeper to be $3h. 55m. 3s$; and by astronomical observations to be $3h. 54m. 20s$; the error being now only $43''$ of time, or $10' 45''$ of longitude. In consequence of this and the former trials Mr. Harrison received one-half of the reward promised, upon making a discovery of the principles upon which his time-keepers were constructed. He was likewise promised the other half of the reward as soon as time-keepers should be constructed by other artists, which should answer the purpose as well as those of Mr. Harrison himself. At this time he delivered up all his time keepers, the last of which was sent to Greenwich to be tried by Mr. Nevil Maskelyne the astronomer royal. On trial, however, it was found to go with much less regularity than had been expected; but Mr. Harrison attributed this to his having made some

experiments with it which he had not time to finish when he was ordered to deliver up the watch. Soon after this an agreement was made by the commissioners with Mr. Kendall to construct a watch upon Mr. Harrison's principles; and this upon trial was found to answer the purpose even better than any that Harrison himself had constructed. This watch was sent out with captain Cook in 1772; and during all the time of his voyage round the world in 1772, 1773, 1774, and 1775, never erred quite $14\frac{1}{2}''$ per day; in consequence of which the house of commons, in 1774, ordered the other £10,000 to be paid to Mr. Harrison. Mr. Harrison had also at different times received other sums of money as encouragement to continue his endeavours, from the Board of Longitude, the East India Company, and from many private individuals, Mr. Arnold, Mr. Mudye, Mr. Ernshaw, and many others have since made many good watches for the same purpose. In 1821 government directed the astronomer royal to receive on trial whatever chronometers might be sent to him for that purpose, and agreed to purchase at a liberal price, every year the three best, provided their going was within certain assigned limits of exactness. In consequence there are always now at the observatory a great number of chronometers sent by the makers on trial, many of which perform most admirably; and indeed it may be said that the great price of chronometers is now the only obstacle to their introduction into general use.

Several astronomical methods have been proposed for finding the time at the first meridian; and any celestial phenomenon, whose times of happening can be predicted, may theoretically be made subservient to that purpose. But, in actual practice, the phenomenon must be such as can without extraordinary difficulty be observed with sufficient nicety; and those depending on the motions of the moon, and the rotation of the satellites of Jupiter round their primary, have been found to be the only ones of any practical value.

The principle on which all astronomical methods of finding the longitude rest is, that the difference between the time of day at meridian, and the time of day at the place of observation, is the longitude of the meridian of that place in time. Now apparent time signifies, or is measured by the angle at the pole included between the meridian of any place and the meridian on which the sun is at that instant. Mean time is the angle included between the meridian of the place, and the meridian on which the mean place of the sun might at the instant be conceived to be. Siderial time is the angle included between the meridian of any place, and the meridian on which the first point of Aries is at the instant.

Let A in the annexed figure represent the first point of Aries; S and S', the true and mean places of the sun; G Greenwich, and B, C, any other two places, P being the pole. Then GPA, GPS, and GPS', are respectively the siderial, apparent, and mean time at Greenwich; BPA, BPS, and BPS', the siderial, apparent, and mean time at B; CPA, CPS, and CPS', the siderial, apparent and mean time at C. Now $GPA - BPA$, or $GPA - BPS$, or $GPA - BPS'$, $= BPG$ the longitude of B, or

of any place on the meridian PB, westerly. And CPA—GPA, or CPS—GPS, or CPS'—GPS', = GPC, the longitude of C, or of any place on the meridian PC, and easterly. Hence it appears that the difference between the sidereal time at the first meridian and the sidereal time at any other meridian is the longitude of that meridian; and that the difference between the mean times, or between the apparent times at the first meridian and that of any other place is the longitude of that other meridian; easterly when the time at the first meridian is behind, and westerly when before the time at the meridian whose longitude it is proposed to find.

If eclipses of the moon happened more frequently they would afford one of the easiest methods of finding the longitude that can be conceived. For the time at the place of observation being noted when the eclipse begins or ends, and compared with the Greenwich time of the corresponding phenomenon as given in the Nautical Almanac, the difference of the times gives the required longitude. It must, however, be observed on this method, that the beginning or end of a lunar eclipse can seldom be determined by observation, to nearer than two or three minutes of time, owing to the gradual shading off of the shadow; and therefore in any single observation the longitude cannot be depended on to nearer than half or three-quarters of a degree.

The eclipses of Jupiter's satellites have been of great use in settling within reasonable limits of exactness the longitudes of places on land; but at sea it has been found impracticable to manage telescopes of sufficient power to note the times at which the eclipses happen. Mr. Irvin invented what he called a marine chair, in which he conceived that even on ship-board a telescope adequate to making such observations might be used with success; but Dr. Maskelyne, who tried it in a voyage to Barbadoes, found that he could derive no benefit from the use of it.

The first and second satellites of Jupiter, as they circulate most rapidly round their primary, are best adapted to the purpose of finding the longitude, but the tables even of their motions are not sufficiently accurate to satisfy the wants of the present state of science. From the observations of the late colonel Beaufoy it appears that the predicted and actual times of an eclipse of the first satellite sometimes differ more than two minutes, though they generally differ less than twenty seconds of time; and with respect to the second satellite the difference in some cases

has been found to amount to nearly three minutes. The method of finding the longitude, from the eclipses of Jupiter's satellites, may therefore be characterised as one which, though easy of application, cannot be depended on as affording results of any very great degree of exactness. Of course the utility of the method will be increased by every improvement in the tables of the motions of the satellites, and every advance that is made in perfecting the construction of telescopes.

The time of the moon's transit over the meridian has also been made subservient to finding the longitude of that meridian. It appears to have been first mentioned by Purchas in his account of Hall's discovery of Greenland; and soon after (in 1635) it was clearly explained in Carpenter's Geography. It is mentioned by Dr. Maskelyne, in his instructions relative to the transit of Venus in 1769; by Bernoulli, and by the abbé Toaldo, in a pamphlet published in 1784; and lastly by Mr. Pigott, who, without knowing that the method had been thought of before, recommended it very strongly to the public, in a paper published in the Philosophical Transactions.

On land, the time of the moon's transit may be determined with great precision with the aid of a transit instrument fixed in the plane of the meridian, and this method is always practised in regular observations. It may also be determined with tolerable accuracy by observing equal altitudes of the moon with a sextant and an artificial horizon, making allowance in the time of the transit, deduced from equal altitudes, for the change of declination in the interval between the observations.

Eclipses of the sun, and the analogous phenomena of occultations of stars by the moon, have also been applied to the finding the time at the first meridian. Mr. F. Baily, in a recent volume of the Memoirs of the Astronomical Society of London, has brought forward, in a new and greatly improved form, the method of finding the longitude from the moon's meridian transit. We merely notice it here as connected with one department of the history of this important problem; and shall recur to it again in a subsequent part of this article.

We have purposely omitted till now, in this historical sketch, to refer to by far the most ingenious and useful method that has ever been proposed for solving this important problem, the method of deducing the longitude from the moon's observed distance from the sun or a star, with the altitudes of both objects. This is commonly called a lunar observation, and from the improvements that have been made in the lunar tables, and in instruments for observing the distance and altitudes, it has been brought to a degree of perfection which fifty years ago could not have been anticipated.

The method consists simply in deducing from the altitudes of the objects, and their distance, with their parallaxes, and the refractions corresponding to their altitudes, what their distance would have been if the observer had been at the centre of the earth; and this distance, compared with those computed and given for

Greenwich time in the *Nautical Almanac*, enables the computer to find the instant at Greenwich when his observation was made; and this time, compared with the time at the place at which he is, gives the required longitude.

John Werner, of Nuremberg, appears to have been the first who proposed this method of finding the longitude in his annotations on the first book of Ptolemy's *Geography*, printed in 1514. It was recommended by Oronce Fine of Briancçon, and again by Gemma Frisius in 1545; and the celebrated Kepler was fully persuaded of its utility. Almost every writer on astronomy down to the time of Flamsteed adverted to it; but even in his day, setting aside the imperfections of the instruments of observation, such was the state of the lunar tables, that he says, 'we find the best tables extant cring sometimes twelve minutes or more from the moon's apparent place, which would cause a fault of half an hour, or $7^{\circ} 30'$ in the longitude, deduced by comparing her place in the heavens with that given by the tables.' This method, therefore, though it appeared to be the only one likely to be applied successfully at sea, was at that time abandoned as impracticable.

But, when Dr. Maskelyne succeeded to the situation of astronomer royal in 1765, such advances had been made in astronomical science, that under his auspices this method of finding the longitude was again brought forward, and after devoting a great portion of his long and valuable life to bring the method to perfection, and to introduce it into practice at sea, he had the satisfaction of seeing his meritorious exertions crowned with almost complete success.

One of the great obstacles to its introduction into general practice was the difficulty in making the necessary calculations from the tables and formulæ which the labors of astronomers had supplied; but this formidable objection was completely obviated by the publication of the *Nautical Almanac*, which, on Dr. Maskelyne's suggestion, was undertaken by the board of longitude in 1766, and it has ever since been continued annually, and is generally published three or four years in advance for the convenience of mariners going on long voyages. Similar publications have since been brought out in several countries in Europe, under the patronage of their respective governments. The French *Connaissance de Temps*, the *Jar Book* of Vienna, and the *Coimbra Ephemeris*, are all similar, and valuable compendiums; and two separate and large editions of the *English Nautical Almanac* are annually published in America.

But before mariners in general could be materially benefited, by all these efforts for their advantage, it was requisite that they should be furnished with such instruments for observing as they could use with readiness, and depend upon with confidence; and with simple as well as appropriate rules for making the necessary computations after their observations were completed.

The artists of this country answered well to the call which this consideration made upon their talents, and devised such improvements in the construction and graduation of quadrants,

sexants, and circles, for nautical observations, that little appears left to be desired on the subject; and, in all the useful problems of nautical astronomy, the methods of calculation have been so simplified that it is not easy to conceive for what situation, connected with the navigation of a ship, the person is fitted who is incapable of applying them.

PRACTICAL DIRECTIONS FOR FINDING THE LONGITUDE.

1. *By a chronometer.*—The error of the chronometer must be found for some known meridian, and its rate or its daily gain, or loss. Call this error e , the rate r , and the number of days from the time that the chronometer had the error e , till it is used for finding the longitude, d , and call the longitude of the place for which the error e was found, l ; then the true mean time T at the meridian of Greenwich may be found from t , the time shown by the chronometer, by the following formula: $T = t + e + dr + \frac{d^2 r^2}{2}$, e being negative when the watch is fast, r negative when the watch is gaining, and l negative in east longitude. And this time, being compared with the mean time at the place as deduced from observation, will give the longitude of the place; west, if the Greenwich time is before, but east if the Greenwich time is behind the time at the place of observation.

Example. If at sea, on October 11th, I find by observation that the mean time is 4h. 2m. 4cs. when a chronometer (which on September 14th was 30m. 2s. fast for mean time at Constantinople, and gaining 4s. per day) showed 7h. 2m. 12s., required the longitude here $d = 27$, $r = -4s.$, $e = -30m. 2s.$, and $l = 12^{\circ} 35'$, $E = -50m. 20s.$. Hence $T = 7h. 2m. 12s. - 30m. 2s. - 1m. 40s. = 50m. 12s. = 6h. 40m. 18s.$; and $6h. 40m. 18s. - 4h. 2m. 40s. = 2h. 37m. 38s. = 39^{\circ} 24' 30''$, the required longitude west.

2. *By the eclipses of Jupiter's satellites.*—Let the Greenwich time of the expected immersion or emersion be looked for in the *Nautical Almanac*, and subtract the supposed longitude of the place of observation from this time, if west, but add it if east, and the result will give the time about which the phenomenon expected ought to be looked for. Let the observer then be settled to his telescope a few minutes before this time, and wait attentively for the instant in which the satellite either enters the shadow, or emerges from it; note the precise instant in mean time at the place when the immersion or emersion is observed; and the difference between that time, and the Greenwich time of the observation as given in the *Almanac*, will be the longitude of the place of observation in time.

Or if at any time afterwards the time at which the eclipse was observed at Greenwich should happen to be known, the difference between that time and the time of the place of observation will give the longitude more exactly than it can be expected to be obtained from a comparison with the computed times in the *Nautical Almanac*. The eclipses, which in favorable weather may be observed at Greenwich, are marked in the *Nautical Almanac* with an asterisk.

Example.—On April 11th I observed by the Nautical Almanac, that the first satellite of Jupiter would emerge from his shadow at 11h. 28m. 4s. Greenwich mean time; I conceived my longitude to be about 9° west, and therefore at about 10h. 45m. I sat down to the telescope, and waited till 10h. 53m. 1s., when I saw the satellite emerge, I therefore concluded that my longitude was 11h. 28m. 4s. — 10h. 53m. 1s. = 35h. 3s. = 8° 4534' west.

3. *By the moon's transit over the meridian.*—If the meridian of a given place, say that of Greenwich, produced to the heavens, were to pass through the sun, the moon, and a fixed star, in the next instant the sun by its motion in right ascension will separate itself from the star, and the moon by her greater motion in right ascension will separate herself still further from the star; or, in other words, at any time after these objects were on the meridian, the star will be the most west of the meridian, the moon least, and the sun in an intermediate position.

The meridian after quitting these bodies will again pass through the star after describing 360° in 23h. 56m. 4.09s., through the sun, after describing 360° 59' 8.3", in 24h., and through the moon in an interval greater than 24h., depending on the daily increase of the moon's right ascension. A spectator on a different meridian would note similar effects; but less in degree as his distance from the first meridian is less. He will note an increase of the sun's right ascension or a separation of the sun from the fixed star, but less than 59m. 8.3s., an increase in the moon's right ascension, but less than its increase between two successive transits; and consequently an excess of the increase of the moon's right ascension above that of the sun's, but less than the excess in the interval between two successive transits of the moon over the first meridian.

Hence, if the increase of the sun or moon's right ascension were known in the interval between two successive transits (and from the Nautical Almanac they can readily be obtained), an observer who could by actual observation determine their right ascensions at the time at which they passed his meridian, might by simple proportion find his longitude, either by comparing the sun and star, the moon and star, or the moon and sun. But, on account of the slow motion of the sun, the first of these methods is of no use in practice; we shall therefore consider only the two latter.

Let A, a , be the respective increases of the right ascensions of the sun and moon in 24h.; then the interval between two successive transits of the moon over any given meridian is 24h.

$\left\{ 1 + \frac{A-a}{24} + \left(\frac{A-a}{24}\right)^2 + \left(\frac{A-a}{24}\right)^3 \&c., \right.$
and the retardation in 24h. is $A - a + \frac{(A-a)^2}{24} + \frac{(A-a)^3}{24^2} + \&c.,$ and the increase

of A due to her retardation is $\frac{A}{24}(A-a) + \frac{(A-a)^2}{24^2} + \frac{(A-a)^3}{24^3} \&c.,$ and consequently $E,$
the increase of her right ascension between two

successive transits, $A + A \left\{ \frac{A-a}{24} + \left(\frac{A-a}{24}\right)^2 + \left(\frac{A-a}{24}\right)^3 + \&c. \right\}$

Hence, if e be the observed increase of the moon's right ascension between her passing the first meridian and that of the place of observation, then the longitude of that place is $24 e \div A.$

$\left\{ 1 + \frac{A-a}{24} + \left(\frac{A-a}{24}\right)^2 + \left(\frac{A-a}{24}\right)^3 \&c. \right\}$

In the case of the sun $E = A - a + \frac{(A-a)^2}{24} + \frac{(A-a)^3}{24^2} \&c.;$ and $e' = e - \epsilon,$

representing the star's acceleration proportional to the time corresponding to the difference of meridians. Hence the longitude = $24 \frac{e - \epsilon}{A - a}$

$\div \frac{A-a}{24} \left\{ 1 + \frac{A-a}{24} + \left(\frac{A-a}{24}\right)^2 + \left(\frac{A-a}{24}\right)^3 \&c. \right\}$

The moon's right ascension is given in the Nautical Almanac for every 12h.; we may therefore employ $\frac{A-a}{2}$, the difference of the increases

of right ascension in 12h., instead of $A - a$, the difference for 24h., using accordingly in the formulæ 12h. instead of 24h.

Though the above divisors in the formulæ for the longitude are infinite series, it will be sufficiently accurate in practice to take the sum of three of their terms.

Example.—If, on April 8th 1800, the right ascension be observed when on the meridian of Greenwich to be 12h. 36m. 26.6s., and on a meridian to the west of Greenwich 12h. 47m. 56.7s. required the longitude of that meridian.

Here 12h. 36m. 26.6s. $\sqrt{12h. 47m. 56.7s. = 11m. 30.1s. = c,}$ and by the Nautical Almanac we have $A = 52m. 6s.,$ and $a = 3m. 39.3s.,$ whence $A - a = 48m. 26.7s.;$ and time of moon's describing $A - a = 50m. 7.8s.,$ for which time the proportional increase of 52m. 6s. is 1m. 48.8s.; hence $E = 52m. 6s. + 1m. 48.8s. = 53m. 54.8s.;$ and consequently 53m. 54.8s. : 11m. 30.1s. :: 24h. : 5.1200h. = 5h. 7m. 12.25s., the required longitude in time.

Mr. Francis Baily, a gentleman who stands at the head of astronomical science in this country, has, in part I. vol. 2 of the Memoirs of the Astronomical Society of London, greatly improved the method of finding the longitude, by the method now under consideration. This method consists in observing with a transit instrument the difference of right ascension between the border of the moon and certain fixed stars previously agreed upon; restricting the observations to such stars as differ very little from the moon in declination. 'It is evident,' he observes, 'that this method is quite independent of the errors of the lunar tables, except as far as the horary motion of the moon in right ascension is concerned, and which in the present case may be depended on with sufficient confidence: that it does not involve any question respecting the compression of the earth: that a knowledge of the correct position of the star is not at all

required; and finally that an error, even of several seconds, in the state of the clock, is of no consequence. Consequently a vast mass of unsatisfactory computation is avoided.'

Since the publication of Mr. Baily's memoir, lists of stars proper to observe with the moon for this purpose have been published in Schumacher's *Astronomia Nachrichten*, and Mr. Baily himself has also published some in this country, the last of which was for the first six months of 1823. These stars have been called moon culminating stars, and several distinguished astronomers have determined the longitude of their observatories by means of them; and lieutenant Forster, the astronomer employed by government in captain Parry's second voyage, applied the method successfully in determining the longitude of Port Bowen.

Let the difference between the time of the transit of the moon's limb and of the fixed star previously agreed on, at the observatory situated most westerly, be denoted by t , and at the observatory situated most easterly by τ . These values will be positive when the transit of the star precedes that of the moon; otherwise they will be negative. Then $t - \tau$ will denote the increase in the right ascension of the moon's limb, in the interval between the observations.

Let us denote, for the apparent time of the moon's culmination at the western observatory, her true radius as seen from the earth by r ; her true declination by d ; and let those quantities at the time of her culmination at the eastern observatory be respectively denoted by ρ and δ . Then $(t - \tau) \pm \frac{1}{15} \left(\frac{r}{\cos. d} - \frac{\rho}{\cos. \delta} \right) = \Delta$

will be the true difference of right ascension of the moon's centre for the two instants of observation; the upper sign being used when the western border of the moon is observed; and the lower sign when the eastern border is observed. But when the difference of meridians is not great we may use the formula in the simple form $t - \tau = \Delta$. The semi-diameter and declination

of the moon above alluded to are such as they are supposed to be if seen from the centre of the earth.

In all cases the longitude required may be supposed to be approximately known; to say within a minute of time. Call this approximate longitude l , and the true longitude λ . Let the apparent time (at the meridian for which the ephemeris employed is computed) of the culmination at the western observatory be denoted by c , and the moon's true right ascension at that time by a ; and let the corresponding time and right ascension at the culmination observed at the eastern observatory be denoted respectively by x and χ ; then $a - x : c - \chi :: \Delta : \lambda$: the angle in time described by the western meridian in the interval of the observations; that is equal to the difference of longitude added to Δ . Whence we have $\lambda = \left(\frac{c - x}{a - x} - 1 \right) \Delta$; or expressing

$\frac{c - x}{a - x}$ in time instead of one, we have $\lambda = \left(15 \cdot \frac{c - x}{a - x} - 1 \right) \Delta$. Or to reduce the time $c - x$, which is apparent, into sidereal time, let $\frac{s}{24h}$ represent the value of a solar day in sidereal

time, and then $\lambda = \left(\frac{s}{24h} \cdot 15 \cdot \frac{c - x}{a - x} - 1 \right) \Delta$ $= \left(\frac{s}{5760} \cdot \frac{c - x}{a - x} - 1 \right) \Delta$; or resuming the value of Δ we have finally $\lambda =$

$\left[t - \tau \pm \frac{1}{15} \left(\frac{r}{\cos. d} - \frac{\rho}{\cos. \delta} \right) \right] \times \left[\frac{s}{5760} \cdot \frac{c - x}{a - x} - 1 \right]$; on which formula it may

be remarked that when more stars than one have been observed on any given night, $t - \tau$ must be taken equal to the mean of all the comparisons made at the same culmination of the moon.

Example.—M. Nicolai at Manheim, and M. Strucer at Dorpat, observed the culmination of the first border of the moon on the 3d of March, 1822; the observations are as under:—

Stars.	Manheim. $t =$	Dorpat. $\tau =$	Diff. $t - \tau =$
1822. 309 Mayer, + 13m. 18.30s.	+ 10m. 17.56s.	3m. 0.71s.	
March 3d, 82 Gemin, + 8 9.42	+ 5 8.25	3 0.88	
μ' Cancri, — 9 41.11	— 12 41.89	3 0.78	

Mean = 3 0.80 = 180.8s.

Manheim.	Dorpat.
$\gamma = 15m. 44.4s.$	$\gamma = 15m. 44.8s.$
$\delta = 23^{\circ} 51' 42''$	$\delta = 24^{\circ} 2' 18''$

And consequently $\frac{1}{15} \left(\frac{\gamma}{\cos. d} - \frac{\delta}{\cos. \delta} \right) = -$

0.123s. whence $\Delta = + 180.8s. - 0.123s. = 180.677$.

To find the values of a and x we must compute by means of second differences the true right ascension of the moon, for the apparent times denoted by c and x ; and the difference between them will be the true motion of the moon in the interval $c - x$. The following are the values deduced from the *Con. des Temps*:—

Manheim.	Dorpat.	Diff.
1822 $c =$	$x =$	$c - x =$
March 3d, 8h. 26m.	7h. — 10m. 1h. — 16m.	

The true semi-diameter and declination of the moon at Manheim and Dorpat, at the above hours, Paris time, will be:

$$c = 8h. 26m. \quad a = 116^{\circ} 49' 24.4''$$

$$x = 7 \ 10 \quad x = 116 \ 4 \ 7.6$$

$$c. - x = \overline{1 \ 16} \quad a - x = 45 \ 16.8$$

The length of a solar day, or the value of s was 86623.4s.; hence we have,

$$\lambda = 180.677s. \left(\frac{86623.4}{5760} \times 1.67845 - 1 \right) = 44.4$$

12m. 59.45s., the difference of longitude between Manheim and Dorpat.

By occultations.—The observations requisite in this method are of the simplest possible character, and, through the skill of modern astronomers, the computations have been greatly simplified. All that is requisite in making the observation is an ordinary telescope, with a watch, or chronometer, and an instrument to find its error for time at the place of observation. Mr. Galbraith of Edinburgh, in his truly valuable Mathematical and Astronomical Tables, has given the following rules for making the computations, being, with a few alterations, the same as those given by Dr. Inman in his Navigation.

From the time at the place of observation, and the estimated longitude, find the estimated Greenwich time; and for that time taken from the Nautical Almanac, the true right ascension of the sun and moon, the moon's true declination, with its change for 10s., for the purpose of repeating the observations if necessary; and the moon's semi-diameter, as well as her horizontal parallax, corrected for the figure of the earth. Take also the moon's true right ascension for 3h. after the first estimated time; and take from the Nautical Almanac, or other tables, the apparent right ascension and declination of the star, and correct the latitude for the figure of the earth, and find in the usual way the star's meridian distance, which is equal, apparent time + sun's R. A. — *'s R. A.

Make four columns and number them (1) (2) (3) (4), and under each write the proportional logarithm of the reduced horizontal parallax. Under (1) and (2) put the secant of the reduced latitude; under (3) the cosecant of the same; under (1) the cosecant of the star's meridian distance (a), and take the sum of the numbers now under (1). Below that sum put the constant logarithm 1.17609 and the cosine of the star's declination; at the same time put under (2) the cosecant, and under (3) the secant of the same; the sum of the three logarithms under (1) will be the proportional logarithm of one first, or the parallax in R. A. in time nearly, one half of which (b) is to be subtracted from (a) giving ($a-b$) the corrected hour angle.

Under (2) put the secant of the hour angle thus corrected. The sum of the logarithms under (3) will be the proportional logarithm of the first part of the parallax in declination, and that under (2) the second part. The first part must be applied with such a sign as to diminish the star's distance from the elevated pole: the second must be applied with the same sign as the first when the hour angle and polar distance are of different affections, otherwise with a contrary sign; and the result will be the true declination of the observed point of the moon's

limbs. Take the difference between this true declination of the observed point and the declination of the moon's centre, found from the Nautical Almanac; under which put the moon's semi-diameter properly corrected, and take the sum and difference. Add together the proportional logarithms of this sum and difference, and to half the sum add the cosine of the mean between the moon's true declination and that just found, and the sum will be the proportional logarithm of the moon's semi-diameter in right ascension nearly.

Under (4) put 1.17609, the first sum under (1) and the cosine of the declination of the observed point, and the sum will be the proportional logarithm of the exact parallax of R. A. in time, which being added to the star's R. A. when west of the meridian, but subtracted if east, will give the true R. A. of the point observed. To the true R. A. thus obtained add the moon's semi-diameter in R. A. or subtract it according as the re-appearance or disappearance of the star has been observed, and the result will be the true right ascension of the moon's centre deduced from the observation. If this differs considerably from the R. A. taken from the Nautical Almanac, alter the moon's declination by as many seconds as will make a corresponding variation in the first R. A. such as the Nautical Almanac would give for the same alteration in the declination. Repeat the operation till this is the case, and the last R. A. will be that required.

Under this put the moon's (1) R. A. taken from the Nautical Almanac for the Greenwich time, and then the moon's R. A. three hours afterwards. Take the difference between the second and each of the others, and from the proportional logarithm of the less difference, subtract the proportional logarithm of the greater, and the remainder will be the proportional logarithm of a portion of time which must be added to the Greenwich time when the first right ascension is greater than the second; or otherwise subtracted, and the result will be the Greenwich apparent time; the difference between which and the apparent time at the place of observation, will be the longitude of that place in time.

Example.—On March 3d, 1823, at Bahia, in latitude $12^{\circ} 57' 17''$ S., longitude by estimation $38^{\circ} 30'$ W., the re-appearance of Antares from the dark limb of the moon, was observed at 15h. 30m. 0.3s.; required the true longitude?

Bahia, March 3d	15h. 30m.
Longitude in time	2 \quad 34

Greenwich estimated time	18 \quad 4
--------------------------	------------

To this time we have the sun's R. A. 22h. 56m. 58.64s., * R. A. 16h. 18m. 35.8s., *'s declination $26^{\circ} 1' 50.1''$ S., *'s R. A. $244^{\circ} 27' 29.75''$, declination $25^{\circ} 55' 15.6''$ S., variation for 10s. $0.63''$ S., semi-diameter $14' 50''$ reduced parallax $54' 26''$; *'s R. A. 3h. after $246^{\circ} 6' 16.82''$; reduced latitude of Bahia $12^{\circ} 52' 17''$ S. Hence *'s meridian distance = apparent time + ☉'s R. A. — *'s R. A. = 22h. 8m. 23.12s., which taken from 24h. leaves 1h. 51m. 36.88s. = $27^{\circ} 54' 13.2'' = a$.

Lieutenant Drinkwater of the royal navy has lately communicated to the astronomical society of London another method of making the preliminary computations for deducing the longitude from an occultation. In his method the sun's right ascension, the moon's declination, horizontal parallax, and semidiameter are taken as in the above method from the Nautical Almanac, for the approximate Greenwich time; the star's meridian distance found, and the latitude and parallax corrected for the earth's ellipticity. Then calling the reduced horizontal parallax P , the star's meridian distance M , its polar distance p , and the latitude l ; he computes arc A , from $\tan. A = \cos. M. \cot. l$; arc B from $B = p + A$; C the principal effect of parallax in polar distance, from $C = P \sin l \sin B$. sect A (—when it is less than p , otherwise +, unless when M exceeds six hours, when it is always —); D the parallax in right ascension, from $D = P. \cos. l. \sin. M. \operatorname{cosect} p$, (—when the star is east of the meridian, otherwise +); and E , the final correction of declination from $E = \frac{D^2 \sin 2 p}{\sin 1''}$ always—.

And, having thus found the declination of the point of occultation, the difference between it and that of the moon's centre is known; and, from this difference, the moon's semidiameter, and the declinations of both objects, the difference between the right ascension of the point of occultation, and that of the moon's centre is found exactly in the same way as in the method given above. Hence the right ascension of the moon's centre is known, and thence, by interpolating in the Nautical Almanac, the Greenwich time of occultation is found. The methods above given for finding the longitude astronomically, require fixed instruments, and particular conjunctions for putting them in practice; we have now to explain the method of finding the longitude by means of the moon's distance from the sun or a star, a method in which neither the observer nor his instrument is required of necessity to be steady, but may be practised under almost any conceivable circumstances of difficulty, and in the absence of clouds may be resorted to whenever the moon is above the horizon, except for two or three days before and after her change.

We have already remarked that the Nautical Almanac was formerly intended to facilitate the finding of the longitude by this particular method; and that in its pages are found the distance of the moon from the sun and certain stars, for every three hours of Greenwich time. It is evident, therefore, that if by any means whatever, instrumental or computative, an observer could determine at any instant the distance of the moon from the sun, or any of the stars for which the Greenwich times, corresponding to her distances, are on the day of observation given in the Nautical Almanac; he may, by referring to that publication, find either at once, or by simple proportion, the precise instant of Greenwich time; and he might thus make the moon serve as the pointer of a Greenwich clock whose face was contained in the pages of the Nautical Almanac. But the distances given in the Nautical Almanac are such as the objects would appear to have if the observer were at the centre of the world; and, as all observations must of necessity be made on the surface, we must determine by computation what they would have been if observed at the centre, before any comparison can be instituted between them and those given in the Nautical Almanac, for the purpose of determining the Greenwich time. This computation is what is known in nautical astronomy by the problem of clearing the lunar distance.

All celestial objects are elevated by refraction above the place in which they would appear if refraction had no existence, and those at which the radius of the earth subtends any sensible angle appear lower, on that account, when observed at the surface, than they would do if they could be viewed from the centre of the earth; this latter deviation of the apparent place of a celestial object from its true place is called the parallax of the object, and varies, as does also the refraction, with the altitude of the object, both vanishing when the object is in the zenith. The moon's parallax varies from a little less than 54' to a little more than 61', according to her distance from the earth. The sun's parallax fluctuates a small fraction of a second above or below 8.75", and may, for the purposes of computation in this problem, be taken equal to 9". The parallaxes of the planets vary according to their distances: that of Venus when nearest the earth is about 30", and when most remote is about 5"; Mars's varies from 21" to about 5"; Jupiter's from 2" to about 1"; and Saturn's from 1' to about 8', and that of the fixed stars is altogether insensible. The moon's, which is by far the largest, as well as the most variable, is given with her semidiameter in the Nautical Almanac for every twelve hours of Greenwich time.

The parallax of an object, when it appears in the horizon, is called its horizontal parallax, and it is that which is meant in the above statement of the parallax of the leading planets in the solar system. When a celestial object is above the horizon, the angle which the radius of the earth on which an observation may be made, subtends at the object, is called the parallax of the object

in altitude. In the annexed figure, let C be the object in the horizon, D its place at the altitude D A C, and B the centre of the earth, then C is the horizontal parallax, and D the parallax in altitude.

Now, as with the same planet C B and B D are equal, we have $C B : B A :: B D : B A$; but $C B : B A :: \text{rad.} : \sin. C$, and $B D : B A :: \sin. B A D$, or $\cos. C A D : \sin. D$; hence $\text{rad.} : \sin. C :: \cos. C A D : \sin. D$; or as radius is to sine of the horizontal parallax; so is cosine of the apparent altitude to the sine of the parallax in altitude. To this proportion the parallax in altitude may be computed when the horizontal parallax is obtained from the Nautical Almanac, or any similar publication.

The difference between the refraction and parallax of a celestial object is called its correction of altitude; and, the parallax of the moon at any altitude being greater than the refraction at the same altitude, her correction of altitude is additive to her apparent altitude to obtain her true altitude. But, with respect to the sun or any planet, the parallax at any altitude is less than the corresponding refraction, and, therefore, for the sun or a planet, the correction of altitude is subtractive from the apparent to obtain the true altitude. And, as the fixed stars have no sensible parallax, the refraction is the sole correction of their altitudes, and subtractive. From what has just been said, we may infer generally that the true place of the moon is above her apparent place, and that the true place of any other celestial object is below its apparent place.

Now the distance of the moon from the sun or a star, being measured with a sextant circle, or other appropriate instrument, the apparent altitudes of the objects must either be taken at the same instant, or determined by calculation, and the problem then occurs to determine from the apparent altitudes and distance (the parallaxes of the objects and the refractions corresponding to the altitudes being also known), what their true distances would be if viewed from the centre of the earth.

In the first place we may remark that the true and apparent places are always in the same vertical circle; and, therefore, that the two spherical triangles formed one by the apparent distance of the objects and their apparent distances from the zenith, and the other by the true distance of the objects and their true distances from the zenith, have the angle included between the vertical circles on which the objects are observed common to both triangles.

Let Z, in the annexed figure, be the zenith, A the apparent place of the moon; M its true place; B the apparent place of the sun or a star; and S its true place; and let C D be the arc of the

horizon, included between the vertical circles ZC and ZD; then AC is the moon's apparent altitude, BD the sun's or star's apparent altitude, MC the moon's, and SD the sun's or star's true altitude, AM the moon's, and BS the sun's or star's correction of altitude, or the difference between the parallax and refraction; AZ is the moon's apparent, and MZ her true zenith distance; and BZ, SZ, are respectively the true and apparent zenith distance of the sun or star.

The computation of MS from the given data is therefore exceedingly simple; for we have only with the apparent zenith distance AZ and BZ (the complements of AC and BD) and the apparent distance AB, to find the angle Z; and then, in the spherical triangle MZS, we have given the angle Z, and the true zenith distances MZ and SZ, to find the true distance MS.

Much time and talent have been applied to

simplify the computations of this very simple problem. The time occupied in taking proportional parts for seconds, in the simple and obvious solution above pointed out, it has been thought might be well spared; and the risk of error in a problem, where seconds of one are important, ought by all practicable means to be diminished. It would be needless to attempt a sketch of many of the expedients which have been devised for this purpose. We shall content ourselves with giving the investigation of two or three of the most practical, and refer to works professedly treating on navigation and nautical astronomy, those who may be desirous of farther information on the subject.

The first which we shall give is that of the chevalier Borda, which requires no tables except the common one of logarithmic sines and cosines.

Let D = the true distance MS (see the above figure); d = the opposite distance AB, A, a , ($90^\circ - ZM$, $90^\circ - ZS$), the true altitudes; and H, h , ($90^\circ - ZA$, $90^\circ - ZB$), the apparent altitudes. *

Then in the triangle SZM, $\cos. Z = \frac{\cos. D - \sin. A \cdot \sin. a}{\cos. A \cdot \cos. a}$; and in the triangle AZB, $\cos.$

$Z = \frac{\cos. D - \sin. H \cdot \sin. h}{\cos. H \cdot \cos. h}$; and by equating these two expressions we have $\cos. D = (\cos.$

$d - \sin. H \cdot \sin. h) \frac{\cos. A \cdot \cos. a}{\cos. H \cdot \cos. h} + \sin. A \cdot \sin. a - (\cos. d + \cos. H + h - \cos. H \cdot \cos. h)$

$\frac{\cos. A \cdot \cos. a}{\cos. H \cdot \cos. h} = 2 \cdot \cos. \frac{H + h + d}{2} \cdot \cos. \frac{H + h \sin d}{2} \cdot \frac{\cos. A \cdot \cos. a}{\cos. H \cdot \cos. h} - (\cos. A \cdot \cos. a - \sin.$

$A \cdot \sin. a)$. But the last term = $\cos. A + a$; subtract both sides of the equation from 1; then; since $1 - \cos. D = 2 \sin. \frac{D}{2}$, and $1 + \cos. \frac{A + a}{2} = 2 \cos. \frac{A + a}{2}$; we have, after dividing

by 2, and putting $F = \frac{\cos. A}{\cos. H} \cdot \frac{\cos. a}{\cos. h} \cdot \sin. \frac{2D}{2} = \cos. \frac{2A + a}{2} - \cos. \frac{H + h + d}{2} \cdot \cos.$

$\frac{H + h \sin d}{2} \times F = \cos. \frac{2A + a}{2} \left(1 - \frac{\cos. \frac{H + h + d}{2}}{\cos. \frac{H + h \sin d}{2}} \right)$. And if we take

$\cos. \frac{H + h + d}{2} \cdot \cos. \frac{H + h \sin d}{2}$

$\cos. \frac{2A + a}{2}$

$\sin. \frac{D}{2} = \cos. \frac{A + a}{2} \cdot \cos. \theta$.

The method which J. de Mendoza Rios selected, and which he compiled his extensive and most valuable collection of tables to facilitate, depends on the same principles as the preceding.

Equating as above, the two expressions for $\cos. Z$, we have $\frac{\cos. D - \sin. A \cdot \sin. a}{\cos. A \cdot \cos. a} =$

$\frac{\cos. d - \sin. H \cdot \sin. h}{\cos. H \cdot \cos. h}$; adding to each, we have $\frac{\cos. A \cdot \cos. a}{\cos. A \cdot \cos. a} + \frac{\cos. D - \sin. A \cdot \sin. a}{\cos. A \cdot \cos. a} =$

$\frac{\cos. H \cdot \cos. h}{\cos. H \cdot \cos. h} + \frac{\cos. d - \sin. H \cdot \sin. h}{\cos. H \cdot \cos. h}$ or, $\frac{\cos. D + \cos. A + a}{\cos. A \cdot \cos. a} = \frac{\cos. d - \cos. H + h}{\cos. H \cdot \cos. h}$;

whence, $\cos. D = (\cos. d - \cos. H + h) \frac{\cos. A \cdot \cos. a}{\cos. H \cdot \cos. h} - \cos. A + a$. Put $\frac{\cos. A \cdot \cos. a}{\cos. H \cdot \cos. h} =$

$2 \cos. N$; or let $\cos. N = \frac{\cos. A \cdot \cos. a \cdot \text{sect. } H \cdot \text{sect. } h}{2 \text{ rad. }^2}$; then we have $\cos. D = (\cos. d -$

$\cos. H + h) 2 \cos. N - \cos. A + a = 2 \cos. d \cdot \cos. N - 2 \cos. H + h \cdot \cos. N - \cos. A + a$
 $= \cos. d + N + \cos. d \cos N + \cos. (H + h + N) + \cos. (H + h \cos N) - \cos. A + a$ or

1 -- cos. $D = 1 + \cos. A + a - \cos. d + N - \cos. d \oslash N - \cos. (H + h + N) - \cos. (H + h \oslash N)$, or, vers. $D = s \cos. A + a - \cos. d + N - \cos. d \oslash N - \cos. (H + h + N) - \cos. (H + h \oslash N)$. Or adding 4, to reduce the cosines to versed sines, and deducting 4 from the same, vers. $D = s \cos. A + a + \text{vers. } d + N + \text{vers. } d \oslash N + \text{vers. } (H + h + N) + \text{vers. } (H + h \oslash N) - 4$, an expression which requires only the addition of five versed sines.

The simplification in this solution depends chiefly on having the auxiliary arc N computed and tabulated, which has been done in a very convenient form.—See Rio's Nautical Tables, Inman's Tables, and Riddle's Navigation and Nautical Astronomy.

The true distance being computed by the methods pointed out above, or by any other of the many formulæ that have been contrived for the purpose, seek in the Nautical Almanac for the distances of the moon from the object whose distance from her has been computed, between which that distance falls,—call the first distance a , and the second, or that three hours after, b , and the time of the first distance t ; then the time corresponding to the true distance D will be

$$t + \frac{3^a a \oslash D}{a \oslash b}. \text{ The numerical result from the}$$

second part of this theorem is greatly facilitated by the use of proportional logarithms. See LOGARITHMS in this work.

After this account of the various methods by which the time at the first meridian may be found, we shall add an account of the chief methods which may be employed for finding the time at the place of observation.

With a transit instrument, which moves in the plane of the meridian, we have simply to notice the time at which a known star comes to the meridian, and the difference between that time and the star's right ascension is the error of the chronometer for sidereal time. Call the time by the clock at which the star passes the meridian T , the star's right ascension r , and the sun's right ascension R , and the equation of time e , then $T \oslash r$, $T \oslash r \oslash R$, and $T \oslash (r \oslash R \pm e)$ are the errors of the clock for sidereal, apparent, and mean time respectively. This observation being repeated on several stars, the error of the clock and its rate may be ascertained with great precision.

$$\sin. \frac{2H}{2} = \text{sect. } l. \cos e \alpha. p \sin \frac{a + l + p}{2}$$

time; the upper sign being used when the object is westward of the meridian, or when the altitude is decreasing, and the lower sign when the object is eastward of the meridian, or when the altitude is increasing. Further, we have $r \pm H - R =$ the apparent time, and this corrected for the equation of time, gives mean time when the altitude was observed.

ON THE METHOD OF ADJUSTING THE SEXTANT.

The adjustments of which this instrument admits are, to make the index and horizon mirrors perpendicular to the plane of the instrument, and the telescope parallel to the same plane; and it is also necessary, previous to making any deductions from observations made with the instrument, to ascertain its index error, that is the

If the time of the sun's passing the meridian be noted, the error of the clock, either for mean or apparent time, will be known.

But it is in few places, whose longitude it is required to determine, that the observer has time to make the delicate adjustments which a transit instrument requires before it can be applied with any advantage in determining the times. Recourse must therefore in general be had to other methods. One of the simplest and best is to take equal altitudes of the same star, east and west of the meridian, noting the times by the clock when each altitude is observed, and half the sum of those times will be the time by the clock when the star is on the meridian; hence the error of the clock is known; and consequently the true time may be known by it, at any given instant, by allowing for the known error, on the time which it shows.

The time may also be found from equal altitudes of the sun observed east and west of the meridian; but, the declination of the sun being variable, a correction on that account, called the equation of equal altitudes, must be applied to the middle time, to obtain the time at which the sun was on the meridian. This correction depends both on the sun's declination, its change in the interval, and the latitude of the place of observation, whereas the two preceding methods are independent of them all. But considerable accuracy in the result will be obtained, without any very exact knowledge either of the latitude or declination, if the change of declination in the interval be exactly known.

If the latitude of the place has been correctly ascertained, the time may be deduced from the altitude of any known celestial object. Let $l =$ the latitude, a the altitude of the object, r its right ascension, R the sun's right ascension, and H the object's meridian distance, then

$$\sin. \left(\frac{a + l + p}{2} - a \right); \text{ and } r \pm H = \text{sidereal}$$

point on the limb at which the zero division of the index stands when the mirrors are parallel.

The index mirror is generally fixed by the maker firmly in its proper position, and in some instruments there are no direct means of adjusting it if it should happen to get out of order.

A B in the annexed figure represents a section of the mirror, and A F B the plane, by which it is attached to the index by means of the three screws C, D, and E. The mirror is known to be in adjustment when the image of the limb of the instrument, seen in it by reflection, is in the same plane with the limb itself; the index

being placed any where on the arch. If the reflected image of the limb appears to incline downward from the plane of the limb, the plane of the limb inclines backward; and, if the instrument has no other means of adjustment, the screws C, D, and E, must be slackened, and a piece of paper, or other thin compressible matter, put below the plane AFB at F, and the screws so tightened that the reflected image of the limb and the limb itself may appear as one continuous plane. If the reflected image appears too high, then a slip of paper must be put below AB, and the screws tightened so that the adjustment may be perfect.

In some instruments the screw E is not a fastening but an adjusting screw, pressing on the plane of the index when screwed in, and consequently giving the plane of the mirror an inclination forward; and the converse when it is slackened. In other instruments the adjustment is effected by a screw acting on a spring, against which the top part of the mirror rests.

The best method of examining the adjustment of the horizon mirror is (having previously adjusted the index reflector) to look at the sun, and, moving the index slowly backwards and forwards, to observe whether the sun, as seen directly, is exactly covered by his reflected image, in passing. If it does the instrument is adjusted. See **SEXTANT**.

In the annexed figure let A represent the sun as seen directly, and let B, C, D, be the image of the sun as passing A, from the motion of the index. If the instrument were in exact adjustment, C would completely cover A. If it does not, the screw, which gives vertical motion to the glass, with reference to the plane of the instrument, must be turned till C and A exactly coincide.

This screw is differently placed, according to the fancy of the maker. For example: AB representing the plane of the mirror; CDEF the apparatus by which it is attached to the plane of the instrument; then the vertical adjustment is made by means of a screw placed as at G, H, I, or K indifferently.

To make the telescope parallel to the plane of the instrument, turn its eye piece till the wires in the focus of it are parallel to the plane of the instrument; then bring the sun and moon, when at a great distance from each other, in apparent contact on the wire nearest the instrument, and immediately bring them on the opposite wire, on which, if they also appear in apparent contact, the line of collimation, or the axis of the telescope, is properly adjusted. If the images should appear to separate or overlap, slacken one of the sunk screws in the collar into which

the telescope is screwed, and lighten the other till the contact of the images is perfect on both wires, when the adjustment will be perfect.

It remains now only to ascertain the index error of the instrument, or the position of the zero of the index, when the index and horizon mirrors are parallel. This may be done in various ways: 1st, Move forward the index till the direct and reflected images of the distant horizon appear as one line; then, if the zero of the index stands on the left of the zero on the limb, what it does so stand to the left is the index error, subtractive. If on the contrary, the index error is additive, 2dly, Make the direct and reflected images of the sun coincide, and the position of the zero will, as above, show the index error. The same may also be effected by making the direct and reflected images of the moon or a bright star coincide. 3dly, Move the index forward, till the reflected image of the sun, as B, exactly touch the limb of the sun, A, as at C; then the difference between the position of the zero of the index and the sun's diameter, as given in the Nautical Almanac, will be the index error;—additive when the diameter is the greater, but otherwise subtractive. 4thly, Bring the limbs of the sun and his reflected image in contact alternately right and left, as at D and E in the annexed

figure, and half the difference of the readings will be the index error, when the zero of the index stands on different sides of zero on the limb; otherwise half the sum of the readings will be the index error; and additive when the greater reading is on the right of the zero on the limb, but subtractive when the greater reading is on the left.

This last is by far the best and most independent method of ascertaining the index error, and it besides affords the observer an excellent opportunity of judging of his skill in estimating a contact; for the distance of the two points at which the index stands, when the reflected image of the sun is in contact with his limb, is double the sun's diameter; hence, by comparing this difference with the known diameter of the sun, an observer may readily discover whether there is any peculiarity or defect in his method of estimating a contact, and he may accordingly endeavour to correct any faulty habit of observing, which such an experiment may show him to have acquired.

The instrument being adjusted, the next object is to take the requisite observations for obtaining the data necessary in the solution of the problem. These are generally the distance of the moon from the sun or a star, with the altitudes of both objects at the same instant. The altitudes are taken in the usual way, either with a quadrant or sextant; the most important element, the distance, requires to be taken with the utmost nicety. Look in the Nautical Almanac for the distance in a rough way between the moon and the required object

DH

at the time of observation, and set the index any way not far from that distance; then look through the telescope at the dimmer object, and turn round the instrument till its plane coincides with one passing through the eye, and the two objects whose distance it is required to measure, and the reflected image of the brighter object will readily be found. Then turn down such screens as may appear necessary, and bring the limbs in contact in the centre of the field of view of the telescope, and the observation will be completed; and the altitudes with the time of observation, as noted by an assistant observer, being read and entered, the observations may be repeated, till half a dozen or more sets are obtained; and the mean of the whole may be taken as a single observation.

If the dimmer object is to the right of the brighter one, there are many persons who find it extremely difficult to hold the instrument in the manner in which it must be then held, if the telescope be pointed as above directed to the dimmer object. Let then the contact be nearly

completed, and screw down the telescope towards the plane of the instrument, turn down the proper screens before the horizon glass, and remove them before the index glass; then look toward the brighter object, and turn the instrument round till the image of the dimmer one is seen, and complete the contact; which, in this position of the instrument, can be done with much greater ease.

It may be observed, however, that this method cannot be satisfactorily practised if the dimmer object is very dim; as the moon during the day at three days old; or as α Arietis near the moon at full. But it is of great importance that whatever difficulties may attend taking this delicate observation should not be increased by mechanical difficulties attending any particular manner of holding the instrument, when these difficulties may be avoided.

For practical examples on the methods of finding the longitudes by observation at sea, see the article NAVIGATION.

LONGLAND, or **LANGLANDE** (Robert), a secular priest, fellow of Oriel College, Oxford, in the fourteenth century, supposed to have been the author of *The Vision of Pierce Plowman*, and *Pierce Plowman's Crede*. He is said to have been a disciple of Wycliffe, his poems being satires on the vice and luxury of the Romish clergy. He hazarded such remarkable prophecies of an impending reformation, in the church, that Warton declares he should have supposed them to have been foisted into the copies, since the suppression of monasteries in England, if he had not seen them in MSS. as old as the beginning of the fifteenth century.

LONGOMONTANUS (Christian), a learned astronomer, born in a village of Denmark in 1562. He was the son of a ploughman, and was obliged to suffer during his studies many hardships, dividing his time, like the philosopher Cleanthes, between the cultivation of the earth and the lessons he received from the minister of the place. At last, when he was fifteen, he left his family, and went to Wiburg, where there was a college, in which he spent eleven years; and, though he was obliged to earn a livelihood, he studied with such ardor that he learned the mathematics in great perfection. He afterwards went to Copenhagen; where the professors of that university recommended him to the celebrated Tycho Brahe. He lived eight years with that famous astronomer, and was of great service to him in his observations and calculations. At length, being extremely desirous of obtaining a professor's chair in Denmark, Tycho Brahe consented to part with him, and furnished him with money for the expense of his journey. He obtained a professorship of mathematics in the university of Copenhagen in 1605; and discharged the duty of it worthily till his death, in 1647. He wrote many learned works: the chief of which is his *Astronomia Danica*; 1640, folio. He also endeavoured to square the circle, and thought he had made that discovery: but Dr. John Pell, an English mathematician, proved that he was mistaken in his calculations.

LONGUEIL (Christopher de), a learned writer, born at Malines in 1490. He was much in favor with several princes. He was employed by pope Leo X. to write against Luther. He wrote also Commentaries on Pliny's book of Plants; and Observations on the Civil Law. He died in 1522.

LONGUERUE (Louis de), a learned French divine, born at Charleville in 1652. He wrote, 1. A Latin dissertation on Tatian; 2. *La Description Historique de la France*; 3. *Annales Arsacidarum*; 4. A Discourse on Transubstantiation; and 5. Remarks on the Life of Cardinal Wolsey.

LONGUS, a Greek sophist, author of a book entitled *Ποσειδάων*, or *Pastorals*; and a romance containing the loves of Daphnis and Chloe. Huetius, bishop of Avranches, speaks very highly of this work, but censures some passages as obscene. As no ancient author mentions Longus, the time when he lived cannot be ascertained. J. Craggs, esq., secretary of state, translated his work into English.

LONICERA, honeysuckle, in botany, a genus of the monogynia order, and pentandria class of plants: cor. monopetalous and irregular: berry polyspermous, bilocular, and inferior.

L. alpeigena, the upright red-berried honeysuckle, rises with a shrubby, short, thick, upright stem, branching strongly and erectly four or five feet high; largish, spear-shaped, leaves, in pairs, opposite; and from the sides of the branches many red flowers by twos on long foot-stalks, each succeeded by two red berries, joined together at their base: it flowers in August, and the berries ripen in autumn.

L. cærulea, the blue-berried upright honeysuckle, rises with a shrubby upright stem, branching moderately three or four feet high, with many white flowers proceeding from the sides of the branches; appearing in May, and succeeded by blue berries joined together at their base.

L. caprifolium, the Italian honeysuckle, rises with shrubby declinated stalks, sending out long

slender trailing branches, terminated by verticillate or whorled bunches of close-sitting flowers, very fragrant; and white, red, and yellow, colors.

L. periclymenum, the common climbing honeysuckle, has two principal varieties, viz. the English wild honeysuckle, or woodbine of our woods and hedges; and the Dutch or German honeysuckle. The former rises with shrubby, weak, very long, slender stalks, and branches trailing on the ground, or climbing round a support; all terminated by oval imbricated heads, furnishing smallish flowers of white or red colors, and appearing from June or July till autumn. The latter rises with a shrubby declinated stalk, and long trailing purplish branches, terminated by oval imbricated heads, furnishing large beautiful red flowers of a fragrant odor, appearing in June and July.

L. sempervirens, the evergreen trumpet-flowered honeysuckle, rises with a shrubby declinated stalk, sending out long slender trailing branches, terminated by naked verticillate spikes, of long, unreflexed, deep scarlet, flowers, very beautiful, but of little fragrance.

L. xylostemum, the fly honeysuckle, rises with a strong shrubby stem, branching erect to the height of seven or eight feet; with erect white flowers, proceeding from the sides of the branches; each succeeded by large double red berries, joined together at their base. The flowers appear in June, and the berries ripen in September. The easiest method of propagating all these plants is by layers and cuttings. In both cases they readily emit roots, and form plants in one year fit for transplantation. Some sorts are also propagated by suckers and seed.

IONS LE SAULNIER, a large town of France, the capital of the department of the Jura. It is agreeably situated on the river Solvan; and has salt springs which ebb and flow, and which have given rise to salt works of considerable extent in the neighbourhood. Here is also a silver mine. Population 7000. Sixty-two miles south-east of Dijon, and 269 south-east of Paris.

LONTAR PULO ISLE, an island in the Indian Ocean, separated by a narrow strait from the peninsula of Malacca. Its inhabitants derive their subsistence from the sea, and appear wholly ignorant of agriculture: the rice they use is procured from the Malays in exchange for fish. Long. 99° 0' E., lat. 70° 30' N.

LOO, *n. s.* From the French palace of Loo, probably. A game at cards.

A secret indignation, that all those affections of the mind should be thus vilely thrown away upon a hand at loo.

Addison.

In the rights of loo.

Pope.

LOOBY, *n. s.* } Welsh *llabc*.—Junius. Or
Loobily, *adv.* } see **LOW**. A stupid, clumsy fellow.

The plot of the farce was a grammar school, the master setting his boys their lessons, and a loobily country fellow putting in for a part among the scholars.

L'Estrange.

The vices trace

From the father's scoundrel race.

Who could give the looby such airs?

Were they masons, were they butchers?

Swift.

LOOCHOO, **LEWCHIEW**, **LIQUEO**, or **LIEOU** ISLANDS, are a group of islands in the Eastern Ocean, to the south of Japan, and about 400 or 500 miles east of China. They consist, according to the accounts of Mr. M'Leod and captain Hall, of thirty-six islands, of which the one called the Great Loochoo is of considerable dimensions, being about fifty miles long, and from twelve to fifteen broad. Its existence was scarcely known to Europeans till it was visited by captain Maxwell and Hall, in their return with lord Amherst from the embassy to China. The part visited by the ships is called Napa-kiang or Napafoo, and is only five miles from Kin-tching the capital and residence of the king. Toward the northern extremity of the island is one of the finest harbours in the world, somewhat similar but far superior, to port Mahon. It was surveyed by captain Hall, and named by him port Melville. Captain Maxwell used every means that prudence would allow to obtain an interview with the king, but this could not be granted, as he did not come in any official character. The king, however, wrote a letter to the prince regent in the Chinese character, which was unfortunately lost when the *Alceste* was wrecked. I was written in a tone of great humility; hoping that the attentions which had been shown to the ships—'the great ship and her little child,'—would be satisfactory to the king of the English.

The whole island exhibited a gentle ascent from the sea, on which 'the grounds were disposed more like the finest country-seats in England than those of an island so remote from the civilised world.' They anchored in front of a town. The climate and soil are among the happiest on the globe. The sea breezes, blowing continually over it, preserve it from the extremes of heat and cold; while its configuration supplies it with rivers and streamlets of excellent water. The fruits and vegetables are consequently of the most exquisite kind: and those of distinct regions are found in a flourishing state. The orange and the lime, the banyan of India, and the Norwegian fir, all thrive here: but the chief object of cultivation is rice. They have also a very nourishing species of sweet potatoe: our ships left them some English ones. The animal creation is of diminutive size, their bullocks seldom weighing more than 350lbs. though plump and well conditioned, and the beef excellent; their goats and pigs are also diminutive, but the poultry large and excellent. The bull is used in agriculture. Few wild animals are seen. The whole coast is surrounded with coral reefs, but abounds in good harbours.

The inhabitants present, however, the most interesting feature of contemplation. They are a small race, the average height of the men not exceeding five feet two inches: but, though small, they are sturdy, well-built, and athletic. They are as fair as the southern Europeans, and have no trace either of Indian or Chinese features.

Captain Hall tells us that numerous parties came off from the shore, and that the deportment of all was modest, polite, timid, and respectful. They had the address however to amuse their visitors a whole fortnight, parrying with

considerable ingenuity every proposal that was made to go on shore, and setting aside with great adroitness every allusion to that subject; giving them at the same time every thing they could possibly want in the way of provisions, and even anticipating their wishes. At length, however, a greater number of boats than usual were observed coming off in a kind of procession, and it was soon discovered that a great man was in one of them. He appeared to be about sixty, and had a cheerfulness of expression and a liveliness of manner remarkable for a man of that age; his manners were graceful and elegant, and from the first moment he seemed to be quite at his ease; every thing about him indicated good breeding, and a familiarity with good society. He examined every part of the *Alceste* with the greatest attention, and seemed to be highly entertained with what he saw. Still, however, there was a strong jealousy exhibited of any attempt to land.

The departure of the *Lyra*, however, to examine the coast, produced the desired effect; the chiefs hastened on board the *Alceste* to enquire what was become of the little ship. Captain Maxwell told them that they had trifled with him so long, and refused to let him land his casks and stores with such obstinacy, that he found it necessary to look out for some more favorable place at which to refit. On hearing this they entreated that he would not think of moving from Napa-kiang; adding that he should have store-rooms on shore for whatever he desired; and that he and his officers might land where they pleased, and walk to the top of the hill without being guarded. In short they now assigned for their immediate use an oblong enclosure, sixty yards by forty, surrounded by a wall twelve feet high. Of this prison (for such it might be considered) they kept undivided possession during the remainder of their stay, which was about a month.

Into the interior of their town, however, the English were never admitted, and even their walks were limited to a certain space. When any attempt was made to pass these bounds, the sentinels interposed by a polite request, and by representing the reproach which would fall upon themselves if the orders of the court were transgressed. Some overtures were made for an audience with the king; but this was declined, on the ground that no embassy or letters were brought from the kind of England. When captain Maxwell toasted the king of Loochoo, they appeared gratified, and in return gave the king of England, whom they appeared to consider as at least his equal. They appeared to live with each other in a very social manner, holding frequent pic-nic parties in the fields; the dinner being carried about in little japanned boxes, with sliding drawers, fastened to the end of a bamboo. A repast to which the English were invited consisted of hard boiled eggs, colored and sliced, fish dried in butter, sliced pork smoked, sliced pig's liver; then tea, which, being new, tasted like an infusion of hay. A dish consisting of a mass of coarse, soft, black sugar, wrapped up in unbaked dough, and powdered over with rice flour, dyed yellow, was the only unpalatable one; the intervals were filled up with sackee, pipes and tobac-

co; and every thing passed off with the greatest good humor. The English saw also specimens of their dancing, which might rather be called hopping, as they jump about on one foot, keeping the other up, clapping their hands, and making a number of extravagant motions; at the same time singing a tune.

Not a single instance of theft occurred during the whole stay of the ships: one striking peculiarity, which may perhaps in part account for this, consists in their being apparently quite strangers to the use of fire-arms, so that the musquetry and shot of the English were objects of great wonder and awe. They appear to have been shocked, however, to see them shooting the birds, but merely requested that they would desist, saying, that they were glad to see them flying about their houses, and offering at the same time a larger supply of fowls. They appeared also to have no money.

Among three or four persons who constantly attended them there was an individual of the name of Madera, whose character is drawn with great ability by captain Hall.

'Two of the natives,' he says, 'have been studying English with great assiduity and with considerable success. One is called Madera, the other Anya. They carry note books, in imitation of Mr. Clifford, in which they record in their own characters every word they learn. They are both keen fellows, and are always among the strangers. From the respect occasionally paid to them it is suspected that their rank is higher than they give out, and that their object in pretending to be people of ordinary rank is to obtain a more free intercourse with all classes on board the ships. Madera, by his liveliness and propriety of manners, has made himself a great favorite; he adopts our customs with a sort of intuitive readiness, sits down to table, uses a knife and fork, converses and walks with us; in short, does every thing that we do, quite as a matter of course, without any apparent effort or study. He is further recommended to us by the free way in which he communicates every thing relating to his country; so that as he advances in English, and we in Loo-choo, he may be the means of giving us much information. As an instance of his progress in English, it may be mentioned that one day he came on board the *Lyra*, and said, 'The Ta-yin speak me, you go ship, John come shore;' by which we understood that captain Maxwell had sent him on board the brig for the interpreter. This was about three weeks after our arrival.'

We cannot resist the temptation of adding this further extract. 'Madera has made great improvement in English, and his character is altogether more developed. He is quite at his ease in our company, and seems to take the most extraordinary interest in every thing belonging to us; but his ardent desire to inform himself on all subjects sometimes distresses him a good deal; he observes the facility with which we do some things, and his enterprising mind suggests to him the possibility of his imitating us; but, when he is made sensible of the number of steps by which alone the knowledge he admires is to be attained, his despair is strongly marked. He

sometimes asks us to read English aloud to him to which he always listens with the deepest attention. One day, on shore, he saw me with a book in my hand: he begged me to sit down under a tree and read: Jeeroo was the only chief present, but there were several of the peasants in attendance upon him; they all lay down on the grass, and listened with an attention and interest which are natural enough: every one expressed himself pleased and satisfied except Madera, whose anxiety was to read in the same manner himself. From the earnest way in which he enquired into every subject, we were sometimes inclined to think that he must have been directed by the government to inform himself on these topics; and certainly a fitter person could not have been selected; for he adapted himself so readily to all ranks, that he became at once a favorite, and every person took pleasure in obliging him.

Jeeroo is esteemed in another way; he is uniformly good humored and obliging, and not without curiosity; but he is not clever, and has none of the fire and enthusiasm of Madera. We all think kindly of Jeeroo, and shake him cordially by the hand when we meet him; but Madera is admired and respected, as well as esteemed, and his society is courted for his own sake.

Madera is about twenty-eight years of age, of a slender figure, and very active; his upper teeth project in front over the lower ones, giving his face a remarkable, but not a disagreeable expression. He is always cheerful, and often lively and playful, but his good sense prevents his ever going beyond the line of strict propriety. When required by etiquette to be grave, no one is so immoveably serious as Madera, and, when mirth rules the hour, he is the gayest of the gay: such indeed is his taste on these occasions, that he not only catches the outward tone of his company, but really appears to think and feel as they do. His enterprising spirit and versatility of talent have led him to engage in a number of pursuits; his success, however, is the most remarkable in his acquisition of English. About a month after our arrival, he was asked what had become of his companion Anya; he replied, 'Anya, him mother sick, he go him mother house;' and when asked if he would return, he said, 'Two, three day time, him mother no sick, he come ship.' With all these endowments and attainments he is unaffectedly modest, and never seems aware of his being superior to the rest of his countrymen. We were a long time in doubt what was his real rank; for at first he kept himself back, so that he was well known to the midshipmen before the officers were at all acquainted with him; he gradually came forward, and, though he always wore the dress of the ordinary respectable natives, his manners evidently belonged to a higher rank, but he never associated with the chiefs, and disclaimed having any pretensions to an equality with them. Notwithstanding all this, there were occasional circumstances, which, by showing his authority, almost betrayed his secret. One morning a difficulty arose about some supplies which the chiefs had engaged to procure, but which they

had neglected to send: as soon as Madera was told of the circumstance, he went to Captain Maxwell, and undertook to arrange it to his satisfaction, at the same time begging that if any difficulty occurred in future, he might be applied to. Whatever may be Madera's rank in his own society, it is highly curious to discover, in a country so circumstanced, the same politeness, self-denial, and gracefulness of behaviour which the experience of civilised nations has pointed out as constituting the most pleasing and advantageous form of intercourse.

The great interest which Madera took in the English, and the curiosity he always expressed about our customs at home, suggested the idea of taking him with us to England, where he would have been an interesting specimen of a people so little known; and he also might have carried back knowledge of the greatest use to his country. When it was proposed to him, he paused for some minutes, and then, shaking his head, said, 'I go Injeree,—father, mother, child, wife, house, all cry I not go; no, no, all cry I go.' This interesting individual they afterward found to be a chief of considerable rank. A few days before they sailed the prince Loo-choo, about fifty years old, and heir to the throne, paid a visit to the *Alceste*, and invited the officers to an entertainment on shore. The bidding a last farewell to this interesting and amiable people was an affecting event.

Sunday, 27th of October.—At day-break we unmoored, and the natives, on seeing us take up one of our anchors, thought we were going to get under weigh immediately, and give them the slip, which was not at all intended. This alarm, however, brought the chiefs off in a great hurry, not in a body in their usual formal way, but one by one, in separate canoes. Old Jeema called on board the *Lyra* on his way to the frigate; he was a good deal agitated, and the tears came into his eyes when I put a ring on his finger. He gave me in return his knife.

The other chiefs called alongside on their way to the frigate, but went on when I told them that I was just going to the *Alceste* myself. In the mean time Madera came on board, with the sextant in his hand; he was in such distress that he scarcely knew what he was about. In this distracted state he sat down to breakfast with us, during which he continued lighting his pipe and smoking as fast as he could; drinking and eating whatever was placed before him. After he had a little recovered himself, he asked what books it would be necessary to read to enable him to make use of the sextant; I gave him a nautical almanac, and told him that he must understand that in the first instance: he opened it, and, looking at the figures, held up his hands in despair, and was at last forced to confess that it was a hopeless business. He therefore put the sextant up and bade us farewell. Before he left the *Lyra* he gave Mr. Clifford his pipe, tobacco pouch, and a crystal ornament; saying, as he held out the last, 'You go Injeree, you give this to your child.'

Mr. Clifford gave him a few presents in return, and expressed his anxiety to be considered his friend. Madera, with the tears streaming

down his cheeks, placed his hand several times upon his heart, and cried, 'Eedooshee, edooshee!' My friend, my friend!

'To me he gave a fan and a picture of an old man looking up at the sun, drawn, he said, by himself; he probably meant in his picture some allusion to my usual occupation at the observatory. After he had put off in his boat, he called out, 'Ingeree noo choo sibiittee yootoosha,' I shall ever remember the English people. When he went to the Alceste, one of the chiefs remarked that he had neither his hatchee-matchee on nor his robes, and told him that it was not respectful to wait upon captain Maxwell, for the last time, in his ordinary dress; particularly as all the others were in full array. Mádera, who, poor fellow, had been too much concerned about other matters to think of dress, was shocked at this apparent want of politeness, and went immediately to apologise to captain Maxwell, who took him by the hand, and gave him a present, telling him, at the same time, that he was always too happy to see him to notice what dress he had on.

'On going into the cabin, I found the chiefs seated in a row, all very disconsolate, and apparently trying to conceal emotions different, in all probability, from any which they had ever before experienced. Captain Maxwell had made them his parting present, and I, therefore, gave to each chief some trifle, receiving from them in return, their knives, pipes, pouches, and fans. In the mean time the anchor was hove up, and, every thing being ready for making sail, the chiefs rose to take leave. Ookooma wished to say something, but was too much affected to speak, and before they reached their boats they were all in tears.

'Mádera cried bitterly as he shook hands with his numerous friends, who were loading him with presents.

'The chiefs, as well as the people in the numerous canoes which had assembled round the ships, stood up, and continued waving their fans and handkerchiefs till we were beyond the reefs, and could see them no longer.'

'Polygamy,' says captain Hall, 'is not allowed in Loo-choo as in China; they invariably spoke with horror of the Chinese practice, which allows a plurality of wives, and were much gratified on learning that the English customs in this respect were similar to those of Loo-choo.' Su-poa-quang asserts, on the contrary, that polygamy is allowed as in China; but that the young men and women see each other before marriage, and choose for themselves. The complete state of degradation in which the females are, from both accounts, indeed, placed, detracts not a little from the many good qualities of these islanders.

LOOF, EAST, or EAST LOW, an ancient borough of Cornwall, incorporated by charter from queen Elizabeth, twelve miles west of Plymouth and 23½ W. S. W. of London. It has two fairs, and a battery of four guns, and is connected with West Looe by a large stone bridge of fifteen arches. It is governed by a mayor, recorder, aldermen, and nine burgesses. It sent two members to parliament (who were chosen by

the mayor, burgesses, and freemen), until the year 1832. The corporation has the toll of the market, and holds the manor of the town of the duchy of Cornwall, at a fee-farm rent of 20s. per annum. The surrounding country is well furnished with gentlemen's seats, and a little higher up the tin works begin. Market on Saturday.

LOOE, WEST, or WEST LOW, a town of Cornwall, opposite to East Looe. It has a fair, was a borough, and sent two members to parliament, the right of election being in the mayor, burgesses, and freemen, in number about fifty-five. West Looe also sent members to parliament, but was disfranchised in 1832. The corporation, by Elizabeth's charter, consists of a mayor, twelve burgesses, &c. West Looe is also called Port Pigham. The manor anciently belonged to the crown, and was annexed by Henry III. to the duchy of Cornwall, of which it is now held by the corporation. Although the harbour is not large, it is commodious, and is defended by a strong battery; the river is navigable for vessels of 100 tons.

LOOFED, adj. From aloof. Gone to a distance.

She once being *looft*, Antony
Claps on his sea-wings, like a doating mallard,
Leaving the fight.

Shakspeare. Antony and Cleopatra.

LOOK, v. n., v. a. & n. s. } Sax *loc*, *locan* ;
LOOK'ER, n. s. } Teut. *lug*, *lügen* ;
LOOK'ING-GLASS. Belg. *louken*. To

see; have the power of vision; seem; have or assume any kind of appearance, air, mien, or manner; to direct the mind's eye or expectation; to watch; take care: as an active verb, to seek; search; regard; influence by looks. It takes almost any of the prepositions after it. The so-called interjection look is clearly the imperative mood of the verb. Look, as a substantive, means air or contour, particularly of the face; the act or exercise of looking or vision. A looker, one who is practising it; a 'looker on,' a mere spectator.

And Jhesus answeride and seide to hem, *lake ye*
that no man deceyve you. *Wiclif. Matt. 24.*

Abimelech *looked* out at a window, and saw Isaac. *Genesis.*

He was ruddy, and of a beautiful countenance,
and goodly to *look* to. *1 Sam. xvi. 12.*

Let us *look* one another in the face.

2 Kings, xiv. 8.

Thou wilt save the afflicted people, but wilt bring
down high *looks*. *Psaln xviii. 27.*

He had *looked* round about on them with anger. *Mark iii.*

If we sin wilfully, after that we have received the knowledge of the truth, there remaineth no more sacrifice for sins, but certain fearful *looking* for of judgment. *Heb. x.*

Looking my love, I go from place to place,
Like a young fawn that late had lost the hind,
And seek each where. *Spenser.*

Being a labour of so great difficulty, the exact performance thereof we may rather wish than *look* for. *Hooker.*

Such labour is then more necessary than pleasant, both to them which undertake it, and for the *lookers* on. *Id.*

She *looks* as clear
As morning roses newly washed with dew.

Shakspeare.

Nay, *look* not big, nor stamp, nor stare, nor fret,
I will be master of what is mine own. *Id.*

Your queen died, she was more worth such gazes
Than what you *look* on now. *Id. Winter's Tale.*

The gods *look down*, and the unnatural scene
They laugh at. *Id. Coriolanus.*

What haste *looks* through his eyes? *Shakspeare.*

His nephew's levies to him appeared
To be a preparation against the Polack;
But, better *looked into*, he truly found
It was against your highness. *Id. Hamlet.*
Thou

Shalt feel our justice, in whose easiest passage
Look for no less than death. *Id. Winter's Tale.*

Let this fellow be *looked to*: let some of my people
have a special care of him. *Shakspeare.*

Thou cream-faced loon!
Where got'st thou that goose *look*?
Shakspeare.

My business in this state
Made me a *looker on* here in Vienna;
Where I have seen corruption boil and bubble
Till it o'er-run the stew. *Id. Measure for Measure.*

Command a mirror hither straight,
That it may shew me what a face I have,
—Go some of you and fetch a *looking-glass*.
Shakspeare.

The state would cast the eye, and *look about* to see
whether there were any head under whom it might
unite. *Bacon.*

In regard of our deliverance past, and our danger
present and to come, let us *look up* to God, and every
man reform his own ways. *Id. New Atlantis.*

In dealing with cunning persons, it is good to say
little to them, and that which they least *look for*.
Id. Essays.

Some come to meet their friends, and to make
merry; others come only to *look on*. *Bacon.*

Look, when the world hath fewest barbarous people,
but such as will not marry, except they know means
to live, as it is almost every where at this day, ex-
cept Tartary, there is no danger of inundations of
people. *Id. Essays.*

Can these, or such, be any aids to us?
Look they as they were built to shake the world,
Or be a moment to our enterprize? *Ben Jonson.*

Did not this fatal war affront thy coast,
Yet satest thou an idle *looker on*? *Fairfax.*

It will import those men who dwell careless to
look about them; to enter into serious consulta-
tion, how they may avert that ruin. *Decay of Piety.*

Pride ever *looks* at the highest. *Bp. Hall.*

If you find a wasting of your flesh, then *look about*
you, especially if troubled with a cough. *Harvey on Consumptions.*

Inordinate anxiety, and unnecessary scruples in
confession, instead of setting you free, which is the
benefit to be *looked for* by confession, perplex you the
more. *Taylor.*

Each seemed to act that part he came to see,
And none was more a *looker-on* than he. *Denham.*

If he long deferred the march, he must *look to* fight
another battle before he could reach Oxford. *Clarendon.*

This mistake was not such as they *looked for*; and,
though the error in form seemed to be consented to,
yet the substance of the accusation might be still in-
sisted on. *Id.*

That which was the worst now least afflicts me,
Blindness, for had I sight, confused with shame,
How could I once *look up*, or heave the head? *Milton.*

Look now for no enchanting voice, nor fear
The bait of honied words. *Id.*

Casting my eye upon so many of the general bills
as next came to hand, I found encouragement from
them to *look out* all the bills I could. *Grant.*

Shepherds *your* pipe, when his harsh sound testifies
anguish, into the fair *looker on*, pastime not passion
enters. *Sidney.*

Do we not all profess to be of this excellent re-
ligion? but who will believe that we do so, that shall
look upon the actions, and consider the lives of the
greatest part of Christians? *Tillotson.*

We are not only to *look at* the bare action, but at
the reason of it. *Stillington.*

Piety, as it is thought a way to the favour of God;
and fortune, as it *looks* like the effect either of that,
or at least of prudence and courage, beget authority.
Temple.

Fate sees thy life lodged in a brittle glass,
And *looks* it through, but to it cannot pass. *Dryden.*

Thus pondering, he *looked under* with his eyes,
And saw the woman's tears. *Id. Knight's Tale.*

Bertran! if thou darest, *look out*
Upon yon slaughtered host. *Id. Spanish Fryar.*

Cowards are offensive to my sight;
Nor shall they see me do an act that *looks*
Below the courage of a Spartan king. *Dryden.*

I must with patience all the terms attend,
Till mine is called; and that long *looked for* day
Is still encumbered with some new delay. *Id.*

Look o'er the present and the former time,
If no example of so vile a crime
Appears, then mourn. *Id. Juvenal.*

Such a spirit must be left behind!
A spirit fit to start into an empire,
And *look* the world to law. *Id. Cleomenes.*

Then on the croud he cast a furious *look*,
And withered all their strength. *Dryden.*
Them gracious Heaven for nobler ends designed,
Their *looks* erected, and their clay refined. *J. Dryden, jun.*

They'll rather wait the running of the river dry,
than take pains to *look about* for a bridge. *I. Strange.*

The dog's running away with the flesh, bids the
cook *look* better to it another time. *Id.*

We should make no other use of our neighbour's
faults, than as a *looking-glass* to mend our own man-
ners by. *Id.*

They will not *look* beyond the received notions
of the place and age, nor have so presumptuous
a thought as to be wiser than their neighbours. *Locke.*

Intellectual beings, in their constant endeavours
after true felicity, can suspend this prosecution in
particular cases, till they have *looked* before them,
and informed themselves, whether that particular
thing lie in their way to their main end. *Id.*

Every one, if he would *look into* himself, would
find some defect of his particular genius. *Id.*

He that gathered a hundred bushels of apples,
had thereby a property in them: he was only to *look*
that he used them before they spoiled, else he robbed
others. *Id.*

Politeness of manners, and knowledge of the world,
should principally be *looked after* in a tutor. *Id. on Education.*

To complain of want, and yet refuse all offers of a supply, *looks* very sullen. *Burnet.*

He *looked upon* it as morally impossible, for persons infinitely proud to frame their minds to an impartial consideration of a religion that taught nothing but self-denial and the cross. *South.*

There is none so homely but loves a *looking-glass*. *Id.*

A solid and substantial greatness of soul *looks down* with a generous neglect on the censures and applauses of the multitude. *Addison.*

Should I publish any favours done me by your lordship, I am afraid it would *look* more like vanity than gratitude. *Id.*

He wished he had indeed been gone,
And only to have stood a *looker on*. *Id. Ovid.*

If a harmless maid
Should ere a wife become a nurse,
Her friends would *look on* her the worse. *Prior.*

Though I cannot tell what a man says; if he will be sincere, I may easily know what he *looks*. *Collier.*

Is a man bound to *look out* sharp to plague himself? *Id.*

Look you! we that pretend to be subject to a constitution, must not carve out our own quality; for at this rate a cobbler may make himself a lord. *Id. on Pride.*

The optick nerves of such animals as *look* the same way with both eyes, as of men, meet before they come into the brain; but the optick nerves of such animals as do not *look* the same way with both eyes, as of fishes, do not meet. *Newton's Opticks.*

It will be his lot to *look* singular, in loose and licentious times, and to become a by-word. *Atterbury.*

The more frequently and narrowly we *look into* the works of nature, the more occasion we shall have to admire their beauty. *Id.*

John's cause was a good milch cow, and many a man subsisted his family out of it: however, John began to think it high time to *look about* him. *Arbuthnot's History of John Bull.*

Those prayers you make for your recovery are to be *looked upon* as best heard by God, if they move him to a longer continuance of your sickness. *Wake's Preparation for Death.*

Where a foreign tongue is elegant, expressive, and compact, we must *look out* for words as beautiful and comprehensive as can be found. *Felton on the Classics.*

This makes it *look* the more like truth, nature being frugal in her principles, but various in the effects thence arising. *Cheyne.*

Late, a sad spectacle of woe, he trod
The desert sands, and now he *looks* a god. *Pope.*

The curious are *looking out*, some for flattery, some for ironies, in that poem, the sour folks think they have found out some. *Swift.*

From the vices and follies of others, observe how such a practice *looks* in another person, and remember that it *looks* as ill, or worse, in yourself. *Watts.*

Look out of your door—take notice of that man; see what disquieting, intriguing, and shifting, he is content to go through, merely to be thought a man of plain dealing; three grains of honesty would save him all his trouble:—alas! he has them not. *Sterne.*

The present life is a state of trial, wherein virtue or holiness is necessary, not only to entitle us to that salvation which, through the mercy of God and the
Vol. XIII.

merits of his Son, Christians are taught to *look for*; but also to prepare us, by habits of piety and benevolence, for a reward; which none but the pure in heart can receive, or could relish. *Beattie.*

The sick penitent, therefore, should be often reminded of this:—that nothing will be *looked upon* as true repentance, but what would terminate in a holy life. *Paley.*

Shakespeare paints so very close to nature, and with such marking touches, that he gives the very *look* an actor ought to wear when he is on his scene. *Cumberland.*

I've *looked* on Ida with a Trojan's eye.

Athos, Olympus, Ætna, Atlas, made
These hills seems things of lesser dignity. *Byron.*

LOOK OUT. There is always a look-out kept on a ship's fore-castle at sea, to watch for any dangerous objects lying near her track, and to which she makes a gradual approach as she advances: the mate of the watch accordingly calls often from the quarter-deck, 'Look out afore there!' to the person appointed for this service.

LOOKING-GLASSES. See **GLASS.**

LOOL, in metallurgy, a vessel made to receive the washings of ores of metals. The heavier or more metalline part of the ores remain in the trough in which they are washed; the lighter and more earthy run off with the water, but settle in the lool.

LOOM, *n. s.* Swed. *lom*; Dan. *loom*; French *lumma*. A sea-fowl.

A *loom* is as big as a goose; of a dark color, dappled with white spots on the neck, back, and wings; each feather marked near the point with two spots: they breed in Farr Island. *Grew.*

LOOM, *n. s.* Sax. *loma*; Goth. *lom*, which also signify **LIMB**, see that word. A jointed frame or instrument of weaving.

Minerva, studies to compose
Her twisted threads, the web she strung,
And o'er a *loom* of marble hung. *Addison.*

A thousand maidens ply the purple *loom*,
To weave the bed, and deck the regal room. *Prior.*

He must leave no uneven thread in his *loom*, or by indulging to any one sort of reproveable discourse himself, defeat all his endeavours against the rest.

Government of the Tongue.

Breathe still softer, or be chid;
And other worlds send odours, sauce, and song,
And robes, and notions, framed in foreign *looms*. *Young.*

These men never destroyed their *looms* till they were become useless, worse than useless; till they were become actual impediments to their exertions in obtaining their daily bread. *Byron.*

LOOM, in weaving, is a machine whereby many distinct threads are woven into one piece. Looms are of various structures, accommodated to the various kinds of materials to be woven, and the various manner of weaving them: viz. for woollens, silks, linens, cottons, cloths of gold; and other works, as tapestry, ribands, stockings, &c., which will be found under their proper heads. See **WEAVING**. The weaver's loom-engine, otherwise called the Dutch loom-engine, was brought into use from Holland to London, in or about 1676. See **COTTON**.
U

LOON, *n. s.* Sax. *lun*, lean; Goth. *laun*; Teut. *lohn* (hire); Scot. *loun*. A servant; a country fellow; a low fellow.

Thou cream-faced loon!

Where got'st thou that goose look?

Shakspeare. Macbeth.

The false loon, who could not work his will
By open force, employed his flattering skill
I hope, my lord, said he, I not offend;
Are you afraid of me that are your friend? *Dryden.*

This young lord had an old cunning rogue, or, as the Scots call it, a false loon of a grandfather, that one might call a Jack of all trades.

Arbuthnot's History of John Bull.

LOONGHEE, a town of the Burmese empire, on the Irrawaddy river, across which is a remarkable ridge of rocks that the natives have a tradition is a petrified cable. The neighbourhood is famous for its fine cattle. Long. 91° 55' E., lat. 19° 41' N.

LOOP, *n. s.* Goth. *laup*; Belg. *loop*,

LOOPER, *adj.* } *loopen*, to run. A running

LOOPHOLE, *n. s.* } knot, or noose; the doubled

LOOPHOLE, *adj.* } part of a string: hence any ornamental double, or fringe consisting of doubles: loophole, an aperture, or hole to give passage: hence evasion; shift; mental doubling.

Fifty loops shalt thou make in the one curtain, and fifty loops shalt thou make in the edge of the curtain that is in the coupling of the second, that the loops may take hold one of another. *Exod. xxvi. 5.*

Nor anie skil'd in workmanship embossed
Nor anie skil'd in loupes of fingering fine,
Might with their diverse cunning ever dare,
With this so curious net-work to compare.

Spenser.

Make me to see't, or at least so prove it,

That the probation bear no hinge, nor loop,
To hang a doubt on. *Shakspeare. Othello.*

Poor naked wretches, wheresoe'er you are,
That bid the pelting of this pitiless storm!
How shall your houseless heads and unfed sides,
Your looped and windowed raggedness, defend you
From seasons such as these? *Id. King Lear.*

The Indian herdsman, shunning heat,
Shelters in cool, and tends his pasturing herds,
At loopholes cut through thickest shades. *Milton.*

Ere the blabbing eastern scout,

The nice morn on the Indian steep,
From her cabined loophole peep. *Id.*

This uneasy loop-holed gaol,
In which y' are hampered by the fetlock,
Cannot but put y' in mind of wedlock.

Hudibras.

Walk not near yon corner house by night; for
there are blunderbusses planted in every loophole, that
go off at the squeaking of a fiddle.

Dryden's Spanish Fryar.

An old fellow shall wear this or that sort of cut
in his cloaths with great integrity, while all the rest
of the world are degenerated into buttons, pockets,
and loops. *Addison.*

Loop, in the iron works, is a part of a sow or block of cast iron broken or melted off from the rest, and prepared for the forge or hammer. The usual method is, to break off the loop of about three-fourths of a hundred weight. This loop they take up with their slinging tongs, and beat it with iron sledges upon an iron plate near the fire, that so it may not fall to pieces, but be in a condition to be carried under the hammer. It is then placed under the hammer, and, a

little water being drawn to make the hammer move but softly, it is beaten very gently, and by this means the dross and foulness are forced off; and after this they draw more and more water by degrees, and beat it more and more till they bring it to a square mass, of about two feet long, which they call a bloom.

LOOPING, in metallurgy, a word used by the miners of some counties of England to express the running together the matter of an ore into a mass, in the roasting or first burning, intended only to calcine it so far as to make it fit for powdering. This accident, which gives the miners some trouble, is generally owing to the continuing the fire too long in this process.

LOORD, *n. s.* Belg. and Teut. *loerd*; Fr. *lourdant*; Erse. *lurdan*. A heavy, stupid, or witless fellow: obsolete. Spenser's Scholiast says, *loord* was wont, among the old Britons, to signify a lord; and therefore the Danes, that usurped their tyranny here in Britain, were called, for more dread than dignity, *lurdant*, i. e. lord Danes, whose insolence and pride was so outrageous in this realm, that if it fortune'd a Briton to be going over a bridge, and to see the Dane set foot upon the same, he must return back till the Dane was clean over, else he must abide no less than present death: but, being afterwards expelled, the name of *lurdane* became so odious unto the people whom they had long oppressed, that, even at this day, they use for more reproach to call the quartan ague the fever *lurdane*. So far the Scholiast, but erroneously. From Spenser's own words, it signifies stupid dulness rather than magisterial arrogance. A drone.

Siker, thou'st but a lazy loord,

And rekes much of thy swinke,
That with foud terms and witless words
To bleer mine eyes do'st think.

Spenser's Pastorals.

LOOSA, in botany, a genus of the monogynia order, in the polyandria class of plants: cal. pentaphyllous, superior; there are five subovate, cucullated, and large petals; the nectarium consists of five leaves, gathered into a conical figure, each terminated by two filaments: caps. is turbinate, unilocular, and trivalved at top; the seeds are very numerous; and there are three linear and longitudinal sinuses.

LOOSE, *v. a., v. n., adj., & n. s.* } Sax. *leaz*,

LOOSELY, *adv.* } *lezan*; Goth.

LOOSEN, *v. n., v. a., & adj.* } *laus*; Swed.

LOOSENESS, *n. s.* } Teut.

Belg. *los*; Dan. *loes*; Gr. *λυσις, λυσω*. To make or set free; unbind; untie; detach; disengage: hence, to deliver from obligation, perplexity, or trouble: as a neuter verb, to set sail or depart by loosing anchor: as an adjective, unshackled; unbound; detached; not fast, fixed, tied, or close; unconnected; hence, free in any sense, not rigid, or accurate; not enslaved or bound to; not strict in expression; vague, indeterminate, or immoral; unchaste; wanton: to break loose is to obtain liberty with more or less of violence; to set loose; to place in a state of liberty or freedom from restraint of some kind: loose as a substantive is a barbarous synonyme of liberty; Bacon uses it for dismissal from:

restraint : to loosen is to separate, part asunder, or lead to separation ; also, as a verb active, to relax ; make less compact or coherent ; free from restraint ; make less costive : the adverb and noun substantive, looseness, follow these senses.

And let the living bird *loose* into the open field.

Lev. xiv.

Canst thou *loose* the bands of Orion ? *Job.*

Lo ! I see four men *loose* walking.

Dan. iii. 25.

The captive hasteneth that he may be *loosed*. *Isaiah.*

Loose him, and bring him to me. *I.uke.*

The shoes of his feet I am not worthy to *loose*.

Acts.

Ye should have hearkened, and not have *loosed* from Crete.

Id.

Art thou *loosed* from a wife ? seek not a wife.

1 Corinthians.

Who is worthy to *loose* the seals thereof ?

Rev. v. 2.

Courtly court he made still to his dame,
Poured out in *looseness* on the grassy ground,
Both careless of his health and of his fame.

Spenser.

Fair Venus seemed unto his bed to bring
Her, whom he waking evermore did ween
To be the chaste flower that ay did spring
On earthly branch, the daughter of a king,
Now a *loose* leman to vile service bound.

Id. Faerie Queene.

Her golden locks for haste were *loosely* shed

About her ears.

Id.

Because conscience, and the fear of swerving from that which is right, maketh them diligent observers of circumstances, the *loose* regard whereof is the nurse of vulgar folly.

Hooker.

We have not *loosely* through silence permitted things to pass away as in a dream.

Id.

The emperor *loosing* from Barcelona, came to the port of Mago, in the island of Minorca.

Knolles.

But in what habit will you go along ?

— Not like a woman ; for I would prevent the *loose* encounters of lascivious men.

Shakspeare.

If he should intend his voyage towards my wife, I would turn her *loose* to him ; and, what he gets more of her than sharp words, let it lie on my head.

Id.

A prince should not be so *loosely* studied, as to remember so weak a composition.

Id.

Loosing thence by night, they were driven by contrary winds back into his port.

Raleigh.

A bishop, living *loosely*, was charged that his conversation was not according to the apostles' lives.

Camden.

It is but a *loose* thing to speak of possibilities, without the particular designs ; so is it to speak of lawfulness without the particular cases.

Bacon.

Air at large maketh no noise, except it be sharply percussed ; as in the sound of a string, where air is percussed by a hard and stiff body, and with a sharp *loose*.

Id.

Fear *looseneth* the belly ; because, the heat retiring towards the heart, the guts are relaxed in the same manner as fear also causeth trembling.

Id. Natural History.

The cause of the casting of skin and shell should seem to be the *looseness* of the skin or shell, that sticketh not close to the flesh.

Id.

He endeavoured to win the common people, both by strained curtesy and by *looseness* of life.

Hayward.

He *loosed* and set at liberty four or five kings of the people of that country that Berok kept in chains.

Abbot.

I account this body nothing but a close prison to my soul ; and the earth a larger prison to my body. I may not break prison, till I be *loosed* by death ; but I will leave it not unwillingly when I am *loosed*.

Ep. Hall.

We ourselves make our fortunes good or bad, and when God lets *loose* a tyrant upon us, or a sickness, if we fear to die or know not to be patient, the calamity sits heavy upon us.

Taylor.

With extended wings a host might pass,

With horse and chariots ranked in *loose* array.

Milton.

From their foundation *loosing* to and fro,
They plucked the seated hills with all their load.

Id.

Part *loosely* wing the region, part more wise
In common, ranged in figure, wedge their way.

Id.

When *loose* epistles violate chaste eyes,
She half consents who silently denies.

Dryden's Ovid.

Ay ; there's the man, who, *loosed* from lust and pelf,

Id.

Less to the pretor owes than to himself.

Id.

She breaks her back, the *loosened* sides give way,

Id.

Like two black storms on either hand,
Our Spanish army and the Indians stand ;
This only space betwixt the clouds is clear,
Where you, like day, broke *loose* from both appear.

Id.

Come, and forsake thy cloying store,
And all the busy pageantry

That wise men scorn, and fools adore :

Come give thy soul a *loose*, and taste the pleasures of the poor.

Id. Horace.

The chiming of some particular words in the memory, and making a noise in the head, seldom happens but when the mind is lazy, or very *loosely* and negligently employed.

Locke.

If to break *loose* from the conduct of reason, and to want that restraint of examination which keeps us from chusing the worse, be liberty, madmen and fools are the only freemen.

Id.

If improvement cannot be made a recreation, they must be let *loose* to the childish play they fancy ; which they should be weaned from, by being made surfeit of it.

Id.

What hath a great influence upon the health, is going to stool regularly : people that are very *loose* have seldom strong thoughts, or strong bodies.

Id. On Education.

He has within himself all degrees of perfection that exist *loosely* and separately in all second beings.

Norris.

This is to cut the knot, when we cannot *loose* it.

Burnet.

Fame makes the mind *loose* and gayish, scatters the spirits, and leaves a kind of dissolution upon all the faculties.

South.

Now I stand

Loose of my vow ; but who knows Cato's thoughts ?

Addison's Cato.

Lucia, might my big swoln heart

Vent all its griefs, and give a *loose* to sorrow,

Marcia could answer thee in sighs.

Id.

The fiery Pegasus disdains

To mind the rider's voice, or hear the reins !

When glorious fields and opening camps he views,

Prior.

He runs with an unbounded *loose*.
A general *looseness* of principles and manners hath seized on us like a pestilence, that walketh not in darkness, but wasteth at noon-day.

Atterbury.

Fat meats, in phlegmatick stomachs, procure *looseness* and hinder retention.

Arbuthnot on Aliments.

When the polypus appears in the throat, extract it that way, it being more ready to *loosen* when pulled in that direction than by the nose. *Sharp's Surgery.*

If an author be *loose* and diffuse in his style, the translator needs only regard the propriety of the language. *Felton.*

Those few that clashed might rebound after the collision; or, if they cohered, yet by the next conflict might be separated again, and so on in an eternal vicissitude of fast and *loose*, though without ever consociating into the bodies of planets. *Bentley.*

The stage how *loosely* does Astræa tread,

Who fairly puts all characters to bed! *Pope.*

Vario spends whole mornings in running over *loose* and unconnected pages, and with fresh curiosity is ever glancing over new words and ideas, and yet treasures up but little knowledge. *Watts on the Mind.*

O ye, to Pleasure who resign the day,
As *loose* in Luxury's clasping arms you lie,
O yet let pity in your breast bear sway,
And learn to melt at Misery's moving cry. *Beattie.*

Loose waved behind her golden train of hair,
Her sapphire mantle swam diffused in air. *Darwin.*

Though slight was the grasp so mortal cold,
He could not *loose* him from its hold. *Byron.*
The treacherous current works its noiseless way,
The fibres *loosen*, and the roots decay;
Prostrate the beauteous ruin lies; and all
That shared its shelter, perish in its fall. *Canning.*

LOP, *v. a. & n. s.* Goth. *leipa*; Swed. *lupa*, from Teut. *laub*, a leaf, as Skinner thinks: but Sax. *lopa* is 'any sudden manner of cutting,' Thomson. To cut off the branches of trees; to cut off abruptly in any way or respect: that which is lopped off.

Or siker thy head very tottie is,
So on thy corbe shoulder it leans amiss;
Now thyself hath lost both *lop* and top,
As my budding branch thou would'st crop. *Spenser.*

Gentle niece, what stern ungente hands
Have *lopped* and hewed, and made thy body bare
Of her two branches, those sweet ornaments? *Shakspeare.*

The gardener may *lop* religion as he pleases. *Howell.*

The plants whose luxury was *lopped*,
Or age with crutches underpropped. *Cleveland.*

Like two pillars,
Or hollowed bodies, made of oak or fir,
With branches *lopped* in wood, or mountain felled. *Milton.*

So long as there's a head,
Hither will all the mountain spirits fly;
Lop that bud off. *Dryden's Spanish Fryar.*
The oak growing from a plant to a great tree, and then *lopped*, is still the same oak. *Lacke.*
Nor should the boughs grow too big, because they give opportunity to the rain to soak into the tree, which will quickly cause it to decay, so that you must cut it down, or else both body and *lop* will be of little value. *Mortimer.*

Rhyme sure in needless bonds the poet ties,
Procrustes like, the ax or wheel applies,
To *lop* the mangled sense, or stretch it into size. *Smith.*

All that denominated it paradise was *lopped* off by the deluge, and that only left which it enjoyed in common with its neighbour countries. *Woodward's Natural History.*

The hook she bore, instead of Cynthia's spear,
To *lop* the growth of the luxuriant year. *Pope.*

The stoical scheme of supplying our wants, by *lopping* off our desires, is like cutting off our feet when we want shoes. *Swift.*

You call these men a mob, desperate, dangerous, and ignorant; and seem to think that the only way to quiet the 'Bellua multorum capitum,' is to *lop* off a few of its superfluous heads. *Byron.*

LOP, a lake and city of Central Asia, on the great road from Cashgar to China. It is situated on the west side of the desert of Shamo, or Cobi. Marco Polo described the caravans as usually stopping here, in his time, to prepare for crossing that extensive tract.

LOPE, pret. of leap. Obsolete.

With that sprang forth a naked swain,
With spotted wings like peacock's train,
And laughing *lope* to a tree. *Spenser's Pastorals.*

LOPIUS, or LOPHIUS, fishing-frog, toad-fish, or sea-devil; a genus of the branchiostegous order of fishes, whose head is in size equal to all the rest of the body. The most remarkable species is *L. piscatorius*, the common fishing-frog, an inhabitant of the British seas. This singular fish was called by the ancients *βαρπαγος*, and rana, for the same reason that we call it the fishing-frog; because it resembles the frog in a tadpole state. Pliny takes notice of the artifice used by it to take its prey: 'It puts forth the slender horns it has beneath its eyes, enticing by that means the smaller fish to play round, till they come within reach, when it springs on them.' The fishing-frog grows to a large size, some bringing between four and five feet long. The fishermen on that coast have a great regard for this fish, from a supposition that it is a great enemy to the dog-fish; and, whenever they take it with their lines, set it at liberty. It is a fish of very great deformity: the head is much bigger than the whole body; is round at the circumference, and flat above, the mouth of a prodigious wideness. Mr. Pennant mentions one taken near Scarborough, whose mouth was a yard wide. The under jaw is much longer than the upper: the jaws are full of slender sharp teeth; in the roof of the mouth are two or three rows of the same: at the root of the tongue, opposite each other, are two bones of an elliptical form, thick set with very strong sharp teeth. The nostrils do not appear externally, but in the upper part of the mouth are two large orifices that serve instead of them. On each side the upper jaw are two sharp spines, and others are scattered about the upper part of the head. Immediately above the nose are two long tough filaments, and on the back three others; these are what Pliny calls cornicula. Along the edges of the head and body are a multitude of short fringed skins, placed at equal distances. The aperture to the gills is placed behind; each of these is very wide, so that some writers have imagined it to be a receptacle for the young in time of danger. The body grows slender near the tail, the end of which is quite even. The color of the upper part of this fish is dusky, the lower part white; the skin smooth.

LOQUACIOUS, *adj.* { Lat. *loquax*, *loqua-*
LOQUACITY, *n. s.* } *cit.* Full of talk or tongue.

Why *loquacity* is to be avoided, the wise man gives sufficient reason: for in the multitude of words there wanteth not sin. Ray.

To whom sad Eve,
Confessing soon; yet not before her judge
Bold, or *loquacious*, thus abashed, replied.

Milton.

In council she gives licence to her tongue,
Loquacious, brawling, ever in the wrong.

Dryden.

Blind British bards, with volant touch
Traverse *loquacious* strings, whose solemn notes
Provoke to harmless revels.

Philips.

Too great *loquacity*, and too great taciturnity by fits.

Arbutnot.

LORANTHUS, in botany, a genus of the monogynia order, in the hexandria class of plants: natural order forty-eighth, aggregatæ: germen inferior: CAL. none: COR. sextid and revolutid; the stamina are at the tops of the petals: **NERRY** monospermous. There is only one species, a native of America, discovered by F. Plumier, and found growing naturally at La Vera Cruz by Dr. Houston. It rises with a shrubby stalk, eight or ten feet high, dividing into several branches, having at their ends clusters of small scarlet-colored flowers, succeeded by oval berries with a pulpy covering, and a hard shell with one cell, enclosing several compressed seeds. It is propagated by seeds, which should be sown soon after they are ripe; otherwise they are very apt to miscarry, or lie a year in the ground without germinating. The plants require always to be kept in a bark stove.

LORARI, among the Romans, officers whose business it was, with whips and scourges to compel the gladiators to engage. They also punished slaves for disobedience.

LORCA, a large town of Murcia, Spain, divided into the Upper and Lower towns, the latter of which is tolerably regular and well built. It has nine churches and several monasteries. The convents worthy of attention are those of St. Jago and St. Domingo. The front of the great church is also elegant. The inhabitants are descendants of the converted Moors. The manufactures of saltpetre are of great extent: and the public walks are considered beautiful. In 1802 this town suffered materially from the bursting of a reservoir in the neighbourhood. It is forty miles S.S. W. of Murcia, and forty-seven west of Carthagenæ. Long. 1° 22' W., lat. 37° 25' N.

LORD, *n. s. & v. n.*

} Superior ruler;
} governor; monarch;

the Supreme Being: a nobleman; a tyrant; a husband; an honorary title of various offices and dignities: to lord is to domineer; assume excessive or despotic authority: *lording* and *lordling* are diminutives of lord, used in ridicule or contempt: *lordliness*, dignity, elevated station; pride; hauteur: *lordly*, befitting or aping a lord: *lordship*, power; dominion; superiority;

seigniority; a title of the British and other peerages, and a compellation of judges; the mayors of London and York, &c.

The Lord said unto my Lord, sit thou at my right hand.

Paulin cx.

What euer seruauantis ben undir ghoke deme thei her *lordis* worthe al honour lest the name of the Lord and the doctrine be blasphemed. Wiclif. 1 Tymo. 6.

The seruauant is not grettere than his lord.

Id. Jon. 13.

They which are accounted to rule over the Gentiles, exercise *lordship* over them, and their great ones exercise authority upon them.

Mark x. 42.

Thinke on the woman Cananee, that saide

That whelpes eten som of the cromes alle

That from her *lordes* table been yfalle.

Chaucer. The Second Nonnes Tale, v. 15528.

Grant harvest lord more by a penny or two,
To call on his fellows the better to do.

Tusser.

Unrighteous lord of love! what law is this,
That me thou makest thus tormented be!

The whiles she *lordeth* in licentious bliss
Of her free will, scorning both thee and me.

Spenser.

How can those grants of the kings be avoided, without wronging of those *lords* which had those lands and *lordships* given them?

Id. On Ireland.

I'll question you

Of my lord's tricks, and yours, when you were boys.

You were pretty *lordings* then.

Shakspeare. Winter's Tale.

Thou vouchsafest here to visit me,

Doing the honour of thy *lordliness*

To one so weak. Id. Antony and Cleopatra.

Bad as yourself, my lord;

An't like your *lordly* lord protectorship?

Shakspeare.

Now being assembled into one company, rather without a lord than at liberty to accomplish their misery, they fall to division.

Hayward.

Needs must the *lordship* there from virtue slide.

Fairfax.

I assure your *lordship*,

The extreme horror of it almost turned me

To air, when first I heard it. Ben Jonson.

There is *lordship* of the fee, wherein the master doth much joy, when he walketh about his own possessions.

Wotton.

Nor were the crimes objected against him so clear, as to give convincing satisfaction to the major part of both houses, especially that of the *lords*.

King Charles.

What a little lord hast thou made over this great earth.

Bp. Hall.

Those huge tracts of ground they *lorded over*, begat wealth, wealth ushered in pride.

Hewel.

They had by this possessed the towers of Gath,
And *lorded over* them whom they now serve.

Milton.

Man over man

He made not lord.

Id.

Of me as of a common enemy,

So dreaded once, may now exasperate them,
I know not: *lords* are *lordliest* in their wine.

Id.

It being set upon such an insensible rising of the ground, it gives the eye *lordship* over a good large circuit.

Sidney.

He was confounded and disanimatd at his presence, and added, How can the servant of my lord talk with my lord?

Boyle's Seraphic Love.

'Tis death to fight, but kingly to controul

Lord-like at ease, with arbitrary power.

To peel the chiefs, the people to devour. Dryden.

But if thy passion *lord* it in thy breast,
 Art thou not still a slave? *Id. Persius.*
 So when a tyger sucks the bullock's blood,
 A famished lion, issuing from the wood,
 Roars loudly fierce, and challenges the food.

Dryden.

What lands and *lordships* for their owner know
 My quondam barber, but his worship now. *Id.*
 We have our author's only arguments to prove,
 that heirs are *lords* over their brethren. *Locke.*

The valour of one man the afflicted throne
 Imperial, that once *lorded* o'er the world,
 Sustained. *Philips.*

I should choose rather to be tumbled into the dust
 in blood, bearing witness to any known truth of our
Lord, than by a denial of truths, through blood and
 perjury wade to a sceptre, and *lord* it in a throne.

South.

Lordly sins require *lordly* estates to support them.
Id.

They called their *lord* Actæon to the game,
 He shook his head in answer to the name.

Addison.

I oft in bitterness of soul deplored
 My absent daughter, and my dearer *lord*.

Pope.

To *lordlings* proud I tune my lay,
 Who feast in bower or hall;
 Though dukes they be, to dukes I say,
 That pride will have a fall. *Swift.*

Traulus, of amphibious breed,
 By the dam from *lordlings* sprung,
 By the fire exhaled from dung. *Id.*
 O'er love, o'er fear, extends his wide domain,
 Unconquered *lord* of pleasure and of pain.

Vanity of Human Wishes.

All hail! inexorable *lord*!
 At whose destruction-breathing word
 The mightiest empires fall!
 Thy cruel, woe-delighted train,
 The ministers of grief and pain,
 A sullen welcome, all! *Burns.*

The sun that overhangs you moors,
 Out-spreading far and wide,
 Where hundreds labour to support
 A haughty *lordling's* pride. *Id.*

LORD is a title of honor given to those who are noble, either by birth or creation, amounting to much the same as peer of the realm. The title is by courtesy also given to all the sons of dukes and marquises, and to the eldest sons of earls. The Saxon word, *hlaford*, is abbreviated from *illaford* to *laford* and *lord*. 'The etymology of the word,' says J. Coates, 'is well worth observing; for it was composed of *illaf*, a loaf of bread, and *ford*, to give or afford; so that *illaford* implied a giver of bread; because, in those ages, such great men kept extraordinary houses, and fed all the poor; for which reason they were called givers of bread, a thing now much out of date, great men being fond of retaining the title, but few regarding the practice for which it was first given.'

LORDS, HOUSE OF, one of the three estates of parliament, composed of the lords spiritual and temporal. The following are among the peculiar privileges of the house of lords:—1. One very ancient privilege is declared by the charter of the forest, confirmed in parliament by 9 Hen. III.: viz. that every lord, spiritual or temporal, summoned to parliament, and passing through the king's forests, may, both in going and

returning, kill one or two of the king's deer without warrant; in view of the forester if he be present, or on blowing a horn if he be absent; that he may not seem to take the king's venison by stealth. 2. They have a right to be attended, and constantly are, by the judges of the court of king's bench and common pleas, and such of the barons of the exchequer as are of the degree of the coif, or have been made serjeants at law; also by the king's learned counsel, being serjeants; and by the masters of the court of chancery, for their advice in point of law, and for the greater dignity of their proceedings. The secretaries of state, with the attorney and solicitor general, also used to attend the house of peers, and have to this day (together with the judges, &c.) their regular writs of summons issued out at the beginning of every parliament, ad tractandum et consilium impendendum, though not ad consentiendum: but whenever, of late years, they have been members of the house of commons, their attendance in the house of lords has fallen into disuse. 3. Every peer, by license obtained from the king, may make another lord of parliament his proxy, to vote for him in his absence; a privilege which a member of the other house can by no means have, as he himself is but a proxy for a multitude of other people. 4. Each peer has a right, by leave of the house, when a vote passes contrary to his sentiments, to enter his dissent on the journal of the house, with the reasons for such dissent; which is usually styled his protest. 5. All bills, that may in their consequences in any way affect the rights of the peerage, are by the custom of parliament to have their first rise in the house of peers, and to suffer no changes or amendments in the house of commons. 6. There is also one statute peculiarly relative to the house of lords, 6 Ann. c. 13, which regulates the election of the sixteen representative peers of North Britain in consequence of the twenty-second and twenty-third articles of the union: and for that purpose prescribes the calls, &c., to be taken by the electors; directs the mode of balloting; prohibits the peers electing from being attended in an unusual manner; and expressly provides that no other matter shall be treated of, in that assembly, save only the election, on pain of incurring a praemunire; and a similar act was passed in 1800, regulating the elections of the Irish peers. See PEERS OF ENGLAND, and GREAT BRITAIN, and LAW.

LORE, *n. s.* Saxon *lær*, *læpan*, to learn; Goth. *lær*. Learning; doctrine; lesson; instruction.

This markis yet his wife to tempten more
 To the uttereste presse of hire corage,
 Fully to have experience and *lore*
 If that she were as stedfast as before.

Chaucer. Cant. Tales.

And, for the modest *lore* of maidenhood,
 Bids me not sojourn with these armed men,
 Oh whither shall I fly? *Fairfax.*

The law of nations, or the *lore* of war. *Id.*

Calm regions once,
 And full of peace; now tost, and turbulent!
 For understanding ruled not; and the will
 Heard not her *lore*! but in subjection now
 To sensual appetite. *Milton's Paradise Lost.*

Lo; Rome herself, proud mistress now no more
Of arts, but thundering against heathen *love*. *Pope*.
But why should foresight thy fond heart alarm?
Perish the lore that deadens young desire! Beattie.

LOREL, *n. s.* Sax. *leopan*. An abandoned
scoundrel. Obsolete.

Silker thou speakest like a lewd *lorell*
Of heaven to deemest so:
How be I am but rude and borrel,
Yet nearer ways I know. *Spenser's Pastorals.*
Thus sayst thou, *lorel*, when thou gost to bed,
And that no wise man nedeth for to wed.

Chaucer. Cant. Tales.

LORENZO, SAN, a town of Mexico, in New
Biscay, termed the vineyard of Cohahuila, the
whole population (about 600) pursuing no other
occupation than the cultivation of the grape. Its
gardens are delightfully interspersed with figs,
vines, apricots, and a variety of other fruits.

LORETTO, a remarkable town of Italy, in
the papal states, near the mouth of the river Mu-
sone. It is situated on the Adriatic, on a com-
manding eminence, and is surrounded with a
rampart and deep ditch, defended by towers.
The principal street is a double row of mean
shops; and the other edifices are little worth
notice. It owes its celebrity entirely to the
Santa Casa, or house said to have been inhabited
by the Virgin Mary of Nazareth, conveyed
hither, as tradition reports, in 1221, by a band
of angels. In the journey from Galilee the same
authority gives these distinguished carriers a rest-
ing place in Dalmatia. The precious relic now
occupies a conspicuous situation in the cathedral,
and is surrounded with a case of the finest mar-
ble, ornamented with beautiful bas reliefs. The
Casa also contains an image of the Virgin, pro-
fusely adorned with precious stones. On the
invasion of Italy, the French republicans
despoiled this church of its treasures; and even
the image of the Virgin was removed to Paris,
but restored in 1802. The town has, it is said,
of late fallen greatly into decay. Population
6000. Twelve miles S. S. E. of Ancona, and 115
of Rome.

LORICA, in Roman antiquity, was a cuirass,
brigantine, or coat of mail, in use among the
soldiers. It was generally made of leather, and
its name is supposed to be derived from *lorum*,
a thong. The loricae were set with plates of
metal in various forms; sometimes in hooks or
rings like a chain, sometimes like feathers, and
sometimes like the scales of serpents or fishes, to
which plates of gold were often added. There
were many other lighter cuirasses, consisting
only of many folds of linen cloth, or of flax
made strong enough to resist weapons. Such
soldiers as were rated under 1000 drachms, in-
stead of the lorica now described, wore a pecto-
rale. The Roman lorica was made like a shirt,
and defended the wearer both before and behind,
but was so contrived that the back part could be
occasionally separated from the front. Some
of the loricae were made of cords of hemp or
flax, closely set together; whence they are
called thoraces, bilices, trilices, &c., from the
number of the cords fixed one upon another;
but these were used rather in hunting than in
battle.

LORICATE, *v. a.* Lat. *lorica*, a crust or
layer of plaster. To plate or plaster over.

Nature hath *loricated*, or plastered over, the sides
of the tympanum in animals with ear-wax, to stop
and entangle any insects that should attempt to creep
in there. *Ray.*

LORME (Philibert de), one of the most cele-
brated architects in the sixteenth century, was
born at Lyons. Queen Catherine de Medicis
gave him the superintendence of buildings; and
he had the direction of those of the Louvre, the
Thuilleries, the castle of St. Anet, St. Germain's,
and other edifices erected by her orders. He
wrote several books of architecture, which are
esteemed: and died about 1577.

L'ORIENT, a fortified modern sea-port of the
north-west of France, and department of the
Morbihan, situated on the bay of Port Louis, at
the influx of the Scorff. It is built with consid-
erable regularity, and the streets are both long and
wide; the public squares spacious and hand-
some; and the harbour large and secure. Ships
of war anchor here in safety, and the trade
of the town was very flourishing under the
French East India Company, who at one time
made it the exclusive entrepôt of their imported
goods. It was declared a free port in 1784, a
privilege which, however, was abrogated at the
revolution. It is still a place of importance, on
account of its magazines for the use of the navy.
Salt is the principal manufacture. An unsuc-
cessful attack was made on it by some British ships,
under general Sinclair and admiral Lestock, in
1746. Population 18,000: 340 miles west by
south of Paris.

LORN, *adj.* Sax. *lope*, *lopan*; Belg. *lior*,
Swed. *lora*. Distressed; forsaken; lost.

Thus hath the kite my love in hire service,
And I am *lorn* withouten remedy.

Chaucer. Cant. Tales.

Who after that he had fair Una *lorn*,
Through light misdeeming of her loyalty.

Faerie Queene.

LORRAIN (Henry de), third duke of Guise,
was the son of duke Francis, and grandson of
Claude, the first duke of Guise; and born in
1550. He was a great general, but of an ambi-
tious and turbulent disposition. He formed the
rebellious association called the league, first
planned by his uncle, the cardinal of Lorraine.
Under pretence of defending the Catholic faith,
he acted in open rebellion against Henry III.,
who at last had him assassinated at Blois, whither
he had summoned the duke to appear before
him on the 23d of December 1587. See FRANCE.

LORRAIN (Robert de), an eminent sculptor,
born at Paris in 1666. He made so rapid a
progress in the art of designing, that, at the age
of eighteen, the celebrated Girardon intrusted
him with the care of teaching his children and
correcting his disciples. He committed to him
also, in conjunction with Noulisson, the execu-
tion of the famous tomb of cardinal Richelieu
in the Sorbonne, and his own tomb at St. Landreu
in Paris. On his return from Rome, he finished
several pieces at Marseilles, which had been left
imperfect by the death of Mr. Puget. He was
received into the academy of sculpture in 1701.

His masterpiece is Galatea, a work universally admired. He afterwards made a Bacchus for the gardens at Versailles, a Faun for those of Marly, and several bronzes, among which is an Andromeda. This artist succeeded chiefly in heads; particularly in those of young girls, which he performed with incomparable delicacy and truth. He died governor of the academy in 1742.

LORRAINE, an extensive district of the north-east of France, between Champagne and Alsace, and divided into the four departments of LA MEUSE, LA MOSELLE, LA MEURTHE, and LES VOSGES. See these articles.

LOS ESTEROS BAY, a bay of the coast of New California, of which the shores fall back about five miles from the ocean. Its north point, Porto del Esteros, is about thirteen miles distant from its southern, which is formed by steep cliffs. Long. of the north point 239° 22' E., lat. 35° 31' N.

LOSE, <i>v. a.</i>	} Sax. leorjan, lorjan; Goth. <i>licesan</i> ; Swed. <i>lisa</i> . To miss; part with; expend; be deprived of; forfeit; alienate; abandon: as a neuter verb, not to win; to fail; decline: loseable is subject to loss or privation: losel is an abandoned worthless fellow: loss is privation; detriment; diminution, or forfeiture of good; particularly the shipwreck of a vessel; uselessness; fault or puzzle, as in the phrase 'at a loss': lost, abandoned; imperceptible.
LOSE'ABLE, <i>adj.</i>	
Lo'SEL, <i>n. s.</i>	
Lo'SER, <i>n. s.</i>	
LOSS,	
Lost, <i>part. adj.</i>	

If salt have *lost* its savour, wherewith shall it be salted? *Matthew.*

The fear of the lord goeth before obtaining of authority; but roughness and pride is the *losing* thereof. *Ecclesi. x. 21.*

He that wole make his lyf saaf schal *lese* it, and he that schal *lese* his lyf for me schal fynde it.

Wiclif. Matt. xvi.

By Cambridge a towne I do know,
Whose *losses* by *lossels* doth shew
More heere then is needfull to tell.

Tusser's Husbandry.

A *losel* wandering by the way,
One that to bounty never cast his mind,
Ne thought of honour ever did assay
His baser breast. *Fucrie Quene.*

The only gain he purchased was to be capable of *loss* and detriment for the good of others. *Hooker.*

Be not with work of *losels* wit defamed,
Ne let such verses poetry be named.

Hubberd's Tale.

He *lost* his right hand with a shot, and, instead thereof, ever after, used a hand of iron. *Kneller.*

I will go *loss* myself

And wander up and down to view the city.

Shakspeare.

We'll hear poor rogues

Talk of court news, and we'll talk with them too,
Who *loses*, and who wins; who's in, who's out. *Id.*

A gross hag!

And, *losel*, thou art worthy to be hanged,

That wilt not stay her tongue. *Id.*

With the *losers* let it sympathize,

For nothing can seem foul to those that win. *Id.*
There succeeded an absolute victory for the English, with the slaughter of above two thousand of the enemy, with the *loss* but of one man, though not a few hurt. *Bacon.*

Nor are constant forms of prayer more likely to flat and hinder the spirit of prayer and devotion, than unpmeditated and confused variety to distract and *lose* it. *King Charles.*

I am impoverished with *losses*; that was never thoroughly good that may be *lost*. *Bp. Hall.*

If thou hast *lost* thy land, do not also *lose* thy constancy; and, if thou must die a little sooner, yet do not die impatiently.

Taylor's Rule of Living Holy.

No man can be provident of his time that is not prudent in the choice of his company; and if one of the speakers be vain, tedious, and trifling, he that hears, and he that answers, are equal *losers* of their time. *Id.*

These sharp encounters, where always many more men are *lost* than are killed or taken prisoners, put such a stop to Middleton's march, that he was glad to retire. *Clarendon.*

Although indeed man was by his fault a great *loser*, and became deprived of great advantages, yet the mercy of God did leave him in no very deplorable estate, simply considered, as to his life here.

Barrow.

The passages through which spirits are conveyed to the members, being almost infinite, and each of them drawn through so many meanders, it is wonderful that they should perform their regular destinations without *losing* their way. *Glanville.*

By them

I *lost* not what I *lost*, rather by them

I gained what I have gained, and with them dwell

Copartner in these regions of the world,

If not disposer.

Milton.

Wisdom in discourse with her

Loses discountenanced, and like folly shews. *Id.*

They have *lost* their trade of woollen drapery.

Graunt.

Consider whether motion, or a propensity to it, be an inherent quality belonging to atoms in general, and not *loseable* by them. *Boyle.*

It cannot last, because that act seems to have been carried on rather by the interest of particular countries, than by that of the whole, which must be a *loser* by it. *Temple.*

How should you go about to *lose* him a wife he loves with so much passion? *Id.*

The lightened coursers ran;

They rushed, and won by turns, and *lost* the day.

Dryden.

Who conquered him, and in what fatal strife
The youth, without a wound, could *lose* his life.

Id.

Her fellow ships from far her *loss* descried:

But only she was sunk, and all were safe beside.

Id.

Reason is always striving, and always at a *lost*, while it is exercised about that which is not its proper object. *Id.*

When the mind pursues the idea of infinity, it uses the ideas and repetition of numbers, which are so many distinct ideas, kept best by number from running into a confused heap, wherein the mind *loses* itself. *Locke.*

The abatement of price of any of the land-holder's commodities, lessens his income, and is a clear *loss*. *Id.*

Losers and malcontents, whose portion and inheritance is a freedom to speak. *South.*

Not the least transaction of *sense* and motion in man, but philosophers are at a *loss* to comprehend. *South's Sermons.*

His seely back the bunch has got

Which Edwin *lost* before.

Parnell.

We should never *lose* sight of the country, though sometimes entertained with a distant prospect of it.

Addison.

In spite of all the virtue we can boast,
The woman that deliberates is *lost*.

Id.

It would be *loss* of time to explain any further our superiority to the enemy in numbers of men and horse.

Id.

The coast

Where first my shipwrecked heart was *lost*.

Prior.

To *lose* these years which worthier thoughts require,

To *lose* that health which should those thoughts inspire.

Savage.

Fame—few, alas! the casual blessing boast,
So hard to gain, so easy to be *lost*!

Pope.

But if to honour *lost*, 'tis still decreed
For you my bowl shall flow, my flocks shall bleed;
Judge and assert my right, impartial Jove.

Pope.

Like following life in creatures we dissect,
We *lose* it in the moment we detect.

Id.

He has merit, good-nature, and integrity, that are too often *lost* upon great men, or at least are not all three a match for flattery.

Pope's Letters.

But rebel with deserts thee oft in vain,
Lost in the maze of words he turns again.

Id.

I do more complain,
Time, health, and fortune are not *lost* in vain.

Id.

Oft in the passions' wild rotation lost,
Our spring of actions to ourselves is *lost*.

Id.

In seventeen days appeared your pleasing coast,
And woody mountains, half in vapours *lost*.

Pope.

When men are openly abandoned, and *lost* to all shame, they have no reason to think it hard, if their memory be reproached.

Swift.

O! *lost* to virtue, *lost* to manly thought
Lost to the noble sallies of the soul!

Who think it solitude to be alone.

Young.

A man may sometimes be at a *loss* which side to close with.

Baker on Learning.

When you have started a good thought, pursue it;
do not presently *lose* sight of it, or suffer any trifling suggestion that may intervene to divert you from it.

Mason.

These pleasures, by repetition, *lose* their relish.

Paley.

Is this man as much overjoyed with gain, and mortified by *losses*, as he was the first day he opened his shop.

Id.

He made no wars, and did not gain
New realms to *lose* them back again.

Byron.

LOT, *n. s.* & *v. a.* } Sax. *hlōt*; Goth. *lut*;
LOTTERY. } Fr. *loterie*; Belg. and Fr.

lot; Swed. *lott*; Ital. *lotto*, all signifying chance.

See LIGHT. Portion; fortune; fate or property assigned: a die, or any thing by which chances are determined: see the quotation from the book of Proverbs. Shakspeare uses it for a good or wished-for chance: *lot*, as a verb, means to dispose of by chances or *lot*: *lottery* is a game or adventure decided by real or supposed chances.

Aaron shall cast *lots* upon the two goats: one *lot* for the Lord, and the other *lot* for the scape-goat.

Lev. xvi. 8.

The *lot* is cast into the lap, but the whole disposal thereof is of the Lord.

Proverbs.

If you have heard your general talk of Rome,
And of his friends there, it is *lots* to blanks

My name hath touched your ears; it is Menenius.

Shakspeare.

Let high-sighted tyranny range on,
Till each man drop by *lottery*.

Id.

The *lottery* that he hath devised in these three chests of gold, silver, and lead, will never be chosen by any but whom you shall rightly love.

Id.

Every warrior may be said to be a soldier of fortune, and the best commanders to have a *lottery* for their work.

South.

Kala at length concludes my lingering *lot*:

Disdain me not, although I be not fair.
Who is an heir of many hundred sheep,
Doth beauty keep which never sun can burn,
Nor storms do turn.

Sidney.

Their tasks in equal portions she divides,
And, where unequal, there by *lots* decides.

Dryden.

Fortune, that with malicious joy
Does man, her slave, oppress,
Still various and inconstant still,
Promotes, degrades, delights in strife,
And makes a *lottery* of life.

Id. Horace.

Our own *lot* is best; and, by aiming at what we have not, we lose what we have already.

L'Estrange.

Prepared I stand; he was but born to try
The *lot* of man, to suffer and to die.

Pope's Odyssey.

Ulysses bids his friends to cast *lots*, to shew that he would not voluntarily expose them to so imminent danger.

Broome.

In a like comparative sense, compared, that is, with the general *lot* of mankind, we call a man happy who possesses health and competency.

Paley.

Poland! o'er which the avenging anger past,
But left thee as he found thee, still a waste,
Forgetting all thy still-enduring claim,
Thy *lotted* people and extinguished name,
Thy sigh for freedom, thy long flowing tear,
That sound that crashes in the tyrant's ear.—

Byron.

And here and there a chestnut stood,
The strong oak, and the hardy pine;

But far apart—and well it were,

Or else a different *lot* were mine.—

Id.

Lor, לוֹר, Heb. i. e. joined together, the son of Haran, nephew of Abraham, and progenitor of the Moabites and Ammonites. His separation from Abraham, his captivity by Chedorlaomer, his restoration by the bravery of his uncle, his extraordinary hospitality, his deliverance from the destruction of Sodom, his wife's metamorphosis, with his fatal intoxication, and involuntary incest, are recorded in Genesis xiii. xiv. and xix. His righteous character is particularly taken notice of by the apostle Peter: 2 Ephesians ii. 7, 8. Some trace the immodest worship of Baal-peor, the god of the Moabites and Ammonites, to the involuntary incest of their ancestor. See BAAL-PEOR.

Lor, a department of France, consists of the ancient Quercy, a dependency of the former province of Guienne, and takes its name from the river Lot, which crosses it from east to west. The principal place of this prefecture is Cahors; it contains three arrondissements or sub-prefectures; Cahors having 113,110 inhabitants, Figeac 85,473, and Gourdon 76,713; making a total population of 275,296 souls, on an area of 5058 square miles. It is subdivided into twenty-nine cantons and 440 communes; yields a territorial

revenue of 11,306,000 francs; forms the twentieth military division, having a royal court at Agen, and a bishopric at Cahors; and is divided into four electoral arrondissements, which send five members to the chamber of deputies.

This department is bounded on the north by that of Correze; on the east by those of Cantal and of Aveyron; on the south by that of Tarn-et-Garonne, and on the west by those of Lot-et-Garonne and Dordogne. It is very hilly; some of the hills are bare, but others are covered with wood and vines, that produce very excellent wine: the plains and valleys yield abundance of corn, hemp, tobacco, and highly esteemed fruits. The pastures feed numerous flocks of sheep, which constitute a great part of the commerce. Game, poultry, and fish, are very plentiful. Part of the wine of the country is made into brandy. The climate is healthy but rather cold. The soil, consisting of fat and rich earth, is cultivated with horses, and yields more than sufficient for its population. There are about 23,000 hectares of forests, and 47,000 of vineyards; producing eighteen francs, fifty-seven cent., for each hectare of arable land.

Iron and coal mines are found here, as well as quarries of marble of every color, granite, alabaster, graystone, mill-stones, lithographic stones, calcareous spar, fullers' earth, and clay for glass-house crucibles. At Mien there are mineral waters. The manufactures are ratteens, coarse serges, hats, cotton stuffs, linen for veils, and lace. The trade consists in corn, flour, wine, brandy, walnut oil, hemp, linens, woollen stuffs, cattle, leather, salt, iron, plank timber, haberdashery, grocery, &c.

This department is watered by the Lot and the Dordogne, which are here navigable, and the medium of great maritime commerce, the Selly, the Tarn, the Aveyron, the Cerc, and the Azou. It is crossed by the great roads of Toulouse and Limoges.

LOT, THE, a river in France, which rises in the Cevennes Mountains, near the village of Bley-mard, arrondissement of Mende, in the department of Lozere. It passes by Bley-mard, Bagnois-les-Bains, Mende, Chanac, St. Geniez, St. Cosme, Espalion, Estaing, Entraygues, Livignac, Bouillac, Capdenac, Cajarc, St. Cirq, Cahors, St. Vincent, Luzech, Puy-L'evêque, Duravel Libos, Villeneuve-d'Agen, St. Livrade, Castelmoron, Clairac, and Aiguillon, below which it falls into the Garonne. The Lot is navigable for timber rafts from St. Laurent-de-Rivedolt to St. Geniez in the department of Aveyron, and navigable from Entraygues to its mouth. In its course, which is about 180 miles, it receives the Truyere, the Dourdon, the Cellé, the Almance, and several other smaller rivers.

LOT-ET-GARONNE, a department of France, is formed out of the Agenais, a dependency of the former province of Guienne, and derives its name from the rivers Garonne and Lot, which flow through it, the first from south to north-east, and the second from north-west to west. The chief place of the prefecture is Agen; it contains four arrondissements or subprefectures, Agen having 84,210 inhabitants; Marmande 99,240; Nérac

57,878; and Villeneuve-d'Agen 92,789, comprising a total population of 330,121 souls, on a superficies of 2565 square miles. It is further subdivided into thirty-eight cantons and 369 communes, yielding a revenue of 20,943,000 francs. It forms a part of the twentieth military division, has a royal court and bishopric at Agen, and contains three electoral arrondissements, which send five members to the chamber of deputies.

This department is bounded on the north by that of Dordogne; on the east by those of Tarn-et-Garonne and Lot; on the south by that of Gers, and on the west by those of Landes and the Gironde. It is intersected by cultivated plains, barren hills, uncultivated lands, marshes, and fine fruitful valleys, watered by the Lot and the Garonne. These valleys overlooked by pleasant elevations planted with fruit trees and vines, which yield tolerably good wines, produce corn in abundance, fruits of all kinds, hemp of an extraordinary tall growth, and the best tobacco in France. Its pastures are but indifferent, and artificial meadows are little known. Towards the south, at a little distance from the Garonne and on the banks of the Lot, the hills become very rugged and utterly incapable of cultivation; in fine, the landes or deserts, which amount to one-eighth part of the whole department, consist of scarcely any thing else than moveable sands, or a scanty vegetation of rye and panic, produced by means of enriching the earth with manure.

The climate of this department is rather temperate, and the air generally healthy, except in the neighbourhood of the marshes. Although the sky here is regarded as the most delightful in France, it is subject to great varieties of rain and drought, which often derange the course of the seasons, and very much injure the harvests. A sort of meteor, called brouillard, is frequently the pest and destruction of the crops. The land being much covered with heath is cultivated with oxen, yielding not quite sufficient for the inhabitants. There are about 26,026 hectares of forests, chiefly oaks, elms, and pines, and 60,000 of vineyards, producing on an average about thirty-four francs sixty centimes per hectare of arable land.

There is here also abundance of great and small game (wild boars, hares, red partridges, &c.), plenty of fresh water fish (salmon, lampreys, shad, and salmon trout); a nursery for the department at Agen; a royal dépôt of standard measures at Villeneuve and quarries of freestone, plaster, marl, potter's clay, &c. The inhabitants carry on extensive manufactures of linen cloth for veils, table linen, cotton goods, printed cottons, and serges; they have also cotton-spinning factories, brandy distilleries, blast furnaces, forges, foundries, flattening-mills, lime-kilns, glass-houses, many paper-mills, tan-yards, currying-shops, dye-houses, &c. Their trade consists in excellent flour, brandy, tobacco, flax, hemp, Agen prunes, bundles of cork, caulking stuff, and tar. The principal rivers that water this department are the Garonne, the Lot, and the Bayse navigable; the Dropt, the Barguelone the Auvignon, the Avance, the Almance, the Lède,

the Gelise, the Gers, the Seine, and the Garonne. It is crossed by the great roads of Mantauban, Auch, and Bourdeaux.

LOTE, *Loros Tree*, or nettle tree, *n. s.* A plant.

The leaves of the *lote* tree are like those of the nettle. The fruit of this tree is not so tempting to us, as it was to the companions of Ulysses: the wood is durable, and used to make pipes for wind instruments: the root is proper for hafts of knives, and was highly esteemed by the Romans for its beauty and use.

The trees around them all their food produce, *Lotos*, the name divine, nectareous juice. *Miller.*
Pope.

LOTHIAN, a name common to the three counties of Scotland, otherwise called Haddington, Edinburgh, and Linlithgow shires; or East, Mid, and West Lothian.

LOTHIAN, EAST, or Haddingtonshire, is bounded on the north-west by the Frith of Forth; on the east by the German Sea; on the south-east by Berwickshire; and on the west by the county of Edinburgh. It extends about twenty-five miles from east to west, and, where broadest, nearly fifteen from north to south. The coast, advancing northward into the Frith, forms an irregular curve. This is one of the most fruitful counties in Scotland, producing great quantities of wheat, and all sorts of grain; and being well watered, and plentifully supplied with fish, fowl, fuel, and all the necessaries of life. It is intersected by numerous streams, but the Tyne is the principal river, which falls into the German Ocean between Berwick and Dunbar. It abounds with towns, villages, and farms, interspersed with a great number of elegant houses belonging to persons of rank and fortune. For cultivation, populousness, and fertility, this shire may vie with any tract of land in Great Britain. The inhabitants on the sea-coast employ themselves in the fishery, salt-making, and foreign trade; and the more inland inhabitants in the linen and woollen manufactures. Great numbers of sheep are fed on the hills of Lammermuir. Prestonpans has a considerable manufacture of oil of vitriol, and sal-ammoniac. It abounds with excellent coal, free-stone, and lime-stone, and produces also some iron and lead.

LOTHIAN, MID, or Edinburghshire, is about thirty-five miles long, but varies in its breadth, in different places, from five to sixteen miles. It is bounded on the east by East Lothian; on the south by the county of Peebles; on the west by that of Linlithgow; and on the north by part of West Lothian and the Frith of Forth. The aspect of the country is in general level and pleasant, interspersed with a few hills. It is well watered with rivers, and shaded with woods; and produces coal and lime stone in abundance, a soft black marble, and some copper ore. The soil, naturally fertile, is finely cultivated, and yields as plentiful harvests of excellent wheat as are found in any part of North Britain. The whole county is interspersed with houses and plantations, belonging to noblemen and gentlemen of fortune; and the farmers are successful agriculturists. The land is generally occupied by tenants on leases for a term of years, excepting the comparatively small portion possessed by the pro-

prietors themselves, or let for the season in grass. Round Edinburgh the cultivation of farms is conducted with a view to the wants of that market; and potatoes, turnips, and clovers, are found more profitable than grain. The manure for raising them is amply supplied by the streets and stables of the city, which sells at 3s. a cubic yard, or more. The street soil, a few years ago, was let out to one individual, and brought the city a clear revenue of £2000 a year. The rent of farms, of from 50 to 100 acres, within a mile of the city, is in some instances so high as £8 or £10 an acre. Beyond this circle the system of cultivation is nearly the same as in the other Scottish counties. The extent of the natural wood has been estimated at 3000 acres, and of plantations about 14,000. The manufactures of the county, inclusive of those of the metropolis and Leith, are not considerable. Distilleries and paper-mills on the Esk, iron-works at Cramond, potteries and salt-pans at Inveresk, and gunpowder works at Temple, on the South Esk, are the principal. The communication between Edinburgh and Glasgow, by means of the Union Canal, promises to be of great utility to this county. The canal itself is five feet deep, and at the surface thirty-seven feet wide, contracting to twenty-two feet at the bottom. It begins at the Lothian Road, west of Edinburgh, and, crossing the Water of Leith at Slateford, passes the villages of Ratho, Broxburn, and Winchburgh, and the towns of Linlithgow and Falkirk, and joins the Forth and Clyde Canal at Lock No. 16, near the village of Camelon, after a course of thirty miles. The aqueducts are, one over the Water of Leith, at Slateford, 500 feet long and fifty feet high; and another of twelve arches of fifty feet span, over the river Avon, two miles above Linlithgow Bridge, 835 feet long, and ninety feet in height above the bed of the river.

The places worthy of note in this county (for it has no town beside Edinburgh of any consequence) are the villages of Mid-Caldor, Corstorphine, and Cramond, north-west; Penicuik, Dalkeith, Laswade, Loanhead, and Gilmerton, east and south; and Musselburgh (sometimes called the Montpelier of Scotland), including the villages of Inveresk and Fishrow, Portobello and Newhaven, on the Frith of Forth. Portobello is a pleasant bathing village, lately built. Hot and cold baths have been constructed upon an elegant plan. Dalkeith, the most populous of these places, is distinguished for its great weekly grain market.

LOTHIAN, WEST, or Linlithgowshire, is bounded on the north by the Frith of Forth; by the Almond, which divides it from Mid-Lothian, on the east. On the south-west it joins the county of Lanark; and on the west it is separated from Stirlingshire by the Avon. Its form, though irregular, approaches to a parallelogram. It measures from north-east to south-west nearly twenty miles. Its breadth, except on the shore of the Frith, does not exceed twelve: its contents are taken at 112 square miles, or 51,006 acres. The country is pleasant and fertile, abounding in corn and pasturage: in the reign of James VI. it had a rich silver mine. Linlithgow contains two royal burghs, viz. Linlithgow and Queensferry; and

the towns of Borrowstounness, Whitburn, Bathgate, and Kirklistoun. It is divided into thirteen parochial districts. The shire is but scantily supplied with running water, the Avon and Almond being the only streams which deserve notice. It abounds, however, with mineral riches, particularly coal, limestone, and lead ore. Ironstone is found in almost every parish; and wrought to a great extent in that of Bathgate. The chief articles of commerce are lime, freestone, salt, and coal. There are volcanic appearances in many places, especially in Dundas Hill, in Dalmeny, where there is a bold front of basaltic rocks, and various regular basaltic columns.

LOTION, *n. s.* Fr. *lotion*; Lat. *lotio*. A medicinal wash.

A *lotion* is a form of medicine compounded of aqueous liquids, used to wash any part with.

Quincy.

In *lotions* in women's cases, he orders two portions of hellebore macerated in two cottle of water.

Arbutnot on Coins.

A **LOTION** is, strictly speaking, such a washing as beautifies the skin, by cleansing it of those deformities which a distempered blood throws upon it. Medicines of this kind, however, are for the most part insignificant, and sometimes very dangerous; the only proper method of treating these disorders is, by administering such medicines as tend to correct that morbid state of the constitution whence they arise.

LOTOPIAGI, in ancient geography, a people of the Regio Syrtica, so called from their living on the lotus; inhabiting between the two Syrtes, from the Cinyphus to the Triton. The lotus was said to be a food so luscious, as to make strangers forget their native country. A sweet wine, according to Pliny, was expressed from it, which did not keep above ten days. See **MENINX**.

The **LOTTERY**, or the **STATE LOTTERY**, a kind of public game at hazard, formerly frequent in Britain, as well as France and Holland; to raise money for the service of the state. It was appointed with us by the authority of parliament, and managed by commissioners appointed by the lords of the treasury for that purpose. It consisted of great numbers of blanks and prizes, which were drawn out of wheels, one of which contained the numbers, and the other the corresponding blanks or prizes. The Romans invented lotteries to enliven their Saturnalia. This festival began by the distribution of tickets which gained some prize. Augustus made lotteries which consisted of things of little value; but Nero established some for the people, in which 1000 tickets were distributed daily, and several of those who were favored by fortune, got rich by them. Heliogabalus invented some very singular lotteries; the prizes were either of great value, or of none at all; one gained a prize of six slaves, and another of six flies; some got valuable vases, and others vases of common earth. A lottery of this kind exhibited an excellent picture of the inequality with which Fortune distributes her favors. The first English lottery we find mentioned in history was drawn A. D. 1569. It consisted of 400,000 lots, at 10s. each lot: the prizes were plate; and the profits were

to go towards repairing the havens of this kingdom. It was drawn at the west door of St. Paul's cathedral. The drawing began on the 11th of January 1569, and continued incessantly drawing, day and night, till the 6th of May following; as Maitland informs us in his History vol. i. p. 257. There were then only three lottery offices in London. The proposals for this lottery were published in 1567 and 1568. It was first intended to have been drawn at the house of Mr. Dericke, her majesty's servant (i. e. her jeweller), but was afterwards drawn as above mentioned. Dr. Rawlinson showed the Antiquarian Society, in 1748, one of the original proposals for this state lottery, printed by Henry Bynneyman, in 1568. In 1612 king James, in favor of the plantation of English colonies in Virginia, granted a lottery, to be held at the west end of St. Paul's; whereof one Thomas Sharplys, a taylor of London, had the chief prize, which was 4000 crowns in plate.

In the reign of queen Anne it was thought necessary to suppress lotteries, as nuisances to the public. After that time, however, they were again licensed by an act of parliament, under various regulations. The act passed in 1778 restrains any person from keeping an office for the sale of tickets, shares, or chances, or for buying, selling, insuring, or registering, without a license; for which licence each office keeper must pay £50, to continue in force for one year, and the produce to be applied towards defraying the expenses of the lottery. And no person is allowed to sell any share or chance less than a sixteenth, on the penalty of £50. All tickets divided into shares or chances are to be deposited in an office, to be established in London by the commissioners of the treasury, who are to appoint a person to conduct the business thereof; and all shares are to be stamped by the said officer, who is to give a receipt for every ticket deposited with him. The numbers of all tickets so deposited are to be entered in a book with the names of the owners, and the numbers of shares into which they are divided; and 2d. for each share is to be paid to the officer on depositing such tickets, who is therewith to pay all expenses incident to the office. All tickets deposited in the office are to remain there three days after the drawing. And any person keeping an office, or selling shares, or who shall publish any scheme for receiving moneys in consideration of any interest to be granted in any ticket in the said lottery, &c., without being in possession of such ticket, shall forfeit £500 and suffer three months' imprisonment. And no business is to be transacted at any of the offices after eight in the evening, except on the evening of the Saturday preceding the drawing. No person is to keep any office for the sale of tickets, &c., in Oxford or Cambridge, on penalty of £20. Within these few years, however, the immoral tendency of this species of state gambling has been so strongly urged upon the ministers that in 1824 they thought proper to abandon it, and lotteries are now therefore discontinued.

LOTUS, or bird's foot trefoil, in botany, a genus of the decandria order, and diadelphia class of plants; natural order thirty-second, papilionaceæ: legume cylindrical and very erect:

the alæ closing upwards longitudinally: CAL. tubulated. There are many species, but only six are usually cultivated in our gardens; viz.

L. Creticus, the Cretan silvery lotus, with slender under shrubby stalk, rising by support three or four feet high, ornamented with trifoliate, bright, silvery leaves; and branches terminated by several yellow flowers succeeded by subternate pods.

L. dorcynium, white Austrian lotus, or shrub trefoil of Montpellier, has under shrubby smooth stalks, branching three or four feet high, and the branches terminated by aphyllous heads of small white flowers, appearing in June, succeeded by small pods.

L. edulis, sends forth several trailing stalks about a foot long, furnished at their joints with trifoliate, roundish, smooth leaves, having oval stipulæ. The flowers come singly from the sides of the stalks, on long peduncles, with three oval floral leaves, the length of the flower: the latter is small, yellow; and is succeeded by a thick arched pod, having a deep furrow on its outside. This species is an annual, and a native of Italy, where the pods are eaten, like kidney beans.

L. hirsutus, the hairy Italian lotus, has upright hairy stalks branching a yard high; and terminated by heads of whitish hoary-cupped flowers appearing in June, and succeeded by oval pods full of seed, which ripen in autumn.

L. Jacobæus, the lotus of St. James's Island, with upright herbaceous stalks, branching two or three feet high; and, from the upper part of the branches, long slender foot-stalks, terminated each by three or five yellowish purple flowers, and succeeded by subternate pods filled with plenty of seeds. These five species may be propagated either by seeds or cuttings, but require to be kept in pots in the green-house during winter.

L. tetragonolobus, or the winged pea, has trailing, slender, branchy stalks, about a foot long, garnished with trifoliate oval leaves; and, from the axillæ of the branches, large, papilionaceous red flowers, one on each foot-stalk; succeeded by tetragonous solitary pods, having a membranous wing or lobe running longitudinally at each corner. It flowers in June and July, and they ripen in autumn. It is a hardy annual, and is easily raised from seed sown between February and May; requiring only to be kept from weeds. It was formerly cultivated here as an esculent; for its young green seed-pods may be dressed and eaten like peas, or kidney beans; and are used so still in the north of England.

Lotus, the lote tree. See **CELTIS**.

Lotus, in mythology, a name generally appropriated to the Egyptian *nymphæa* lotus, but also applied to the *κνᾶμος* or sacred bean of India, to some African tree on which certain people have chiefly depended for their support, and also to several herbaceous plants essential to the maintenance of domestic cattle in countries sparingly furnished with grass. The origin of this word has been much disputed. Those who have sought for its etymology in the Greek language, have derived it from *λω*, to *will* or *desire*, alluding to its being greatly esteemed.

Others have thought that both the *λωτος* of the Greeks and the lotus of the Latins had one common Egyptian origin inscrutable to us.

This plant is thus noticed by Herodotus. 'When the river Nile is become full, and all the grounds round it are a perfect sea, there grow a vast quantity of lilies, which the Egyptians call lotus, in the water. After they have cut them, they dry them in the sun; then having parched the seed within the lotus, which is most like the poppy, they make bread of it, baking it with fire. The root also of the lotus is eatable, easily becoming sweet, being round, and of the size of an apple.' M. Savary mentions it as growing in the rivulets and on the sides of the lakes; and there are two sorts or varieties of the plant, the one with a white, the other with a bluish flower. 'The calyx,' he says, 'blows like a large tulip, and diffuses a sweet smell, resembling that of the lily. The first sort produces a round root like that of a potatoe; and the inhabitants of the banks of the lake Menzel feed upon it. The rivulets in the environs of Damietta are covered with this majestic flower, which rises upwards of two feet above the water.'

It is not improbable that this flower became sacred to superstitious veneration, in that country, in consequence of its resemblance to the East India lotus, a kind of bean. The latter, from the mode of its vegetation, was adopted, in the most remote ages, to serve as an emblem of fertility; but the *nymphæa* lotus exhibits nothing which could originally have excited such an idea. It seems therefore a sort of substitute or type; and perhaps strengthens the theory of the mythology of Egypt having migrated thither from India. Among the Brahmins, and enthusiastic Hindoos, no object in nature is looked on with more superstition than the lotus; and their books abound with mystical allusions to this lovely aquatic. In the northern parts of India the petals of the lotus are blue, as well as red and white; while in the southern provinces the blue flower is not seen: the poets have hence feigned that the crimson hue was imparted to it by the blood of Siva issuing from the wound made by the arrow of Kama, when the god of love daringly endeavoured to inspire the 'king of dread' with an amorous passion, for which presumption he was reduced to ashes, or, as some say, to a mental essence, by the fire which issued from the forehead of the 'three-eyed god.' The following extract from the curious and learned dissertation of major Wilford, On the sacred Isles of the West, will serve to show the wild extravagance of Hindoo mythologists: 'The *nymphæa*, or lotus, floating on the water, is an emblem of the world; the whole plant signifies both the earth and its two principles of fecundation. The stalk originates from the navel of Vishnu, sleeping at the bottom of the ocean; and the flower is the cradle of Brama, or mankind. The germ is both Meru and the Linga; the petals and filaments are the mountains which encircle Meru, and are also the type of the Yoni.' (*Asiatic Researches*, vol. viii.)

Lotus *GLYCICALAMUS*, a name given by the ancient Greeks to an Egyptian plant according to some, and, according to others, to a rare plant, found only occasionally. The whole account

given of it, by the earliest writers, is no more than that it was of a very sweet and pleasant taste. Myrepsus uses the term frequently, and his interpreters understand him to mean the cassia fistula by it. But Homer asserts that the followers of Ulysses were detained by eating the lotus glycycalemus; and it is not at all probable that the cassia fistula could be the thing meant by the word in this place. The cassia fistula is the fruit of a tree: but this glycycalemus, we find in Homer himself, was an herbaceous plant. Quintilian calls it expressly a kind of grass, gramin; and from the other accounts of its growing in the form of reeds, and in wet places, it seems probable that it was the sugar-cane that they called by this name. See DIOSPYROS.

LOUD, *adj.* } Sax. *lud*; Goth. *lud*, of
LOUD'LY, *adv.* } Goth. *hlyda*, to hear; Swed.
LOUD'NESS, *n. s.* } *liud*; Tent. *laut*. Sounding; remarkable for force or vehemence of sound; noisy; clamorous: the adverb and substantive corresponding.

She is *loud* and stubborn; her feet abide not in her house. *Proverbs.*

The soldier that philosopher well blamed.

Who long and *loudly* in the schools declaimed. *Dentham.*

Children may be frightened into compliance by *loud* and severe increpations, but men are to be allured by rational persuasion backed with courteous usage. *Barrow.*

Had any disaster made room for grief, it would have moved according to prudence, and the proportions of the provocations: it would not have sallied out into complaint or *loudness*. *South.*

The numbers soft and clear,

Gently steal upon the ear;

Now *louder*, and yet *louder* rise,

And fill with spreading sounds the skies. *Id.*

I read above fifty pamphlets, written by as many presbyterian divines, *loudly* disclaiming toleration. *Swift.*

Sir, when I flew to seize the bird

In spite of your command,

A *louder* voice than yours I heard,

And harder to withstand. *Cowper.*

Like a scarce awakened ocean,

Then with stronger shock and *louder*.

Till the rocks are crushed to powder. *Byron.*

LOVE, *v. a. & n. s.*

LOVE'HOOD, *n. s.*

LOV'INGKIND'NESS, *n. s.*

LOV'INGLY, *adv.*

LOV'INGNESS, *n. s.*

Sax. *lufa*, *lufian*;

Goth. *love*, *liub*;

Belg. *lief*; Swed.

luif; Teuton. *leebe*.

The affection between the sexes;

courtship; tenderness;

liking or affection of any kind;

good will; friendship;

an endearing compellation; an

object beloved; a

picturesque representation of love:

as a verb it signifies

to regard with

sexual passion or

affection; regard or

be pleased with in

a general sense, and

in varying degrees

of attachment, esteem, or reverence, according to the object. *Lovely* means amiable; exciting love; beautiful. *Lovesome* is used in the same sense by Dryden. *Loving* is fond; kind; affectionate. *Lovingkindness*, favor; tenderness; mercy: applied particularly to that of the Divine Being. The other compounds are sufficiently explained by the extracts.

This is my commandment, that *ghe loue togidre* as I *louyde* ghout: no man hath more *loue* than this that a man putte his lyf for hise frendis.

Wiclif, Jon xv.

Love the Lord thy God with all thine heart.

Deut. vi. 5.

Saul and Jonathan were *lovely* and pleasant in their lives, and in their death they were not divided.

2 Samuel.

Remember, O Lord, thy tender mercies, and thy *lovingkindnesses*.

Psaln xxv. 6.

God brought Daniel into favour and tender *love* with the prince.

Daniel i. 9.

The king took her in his arms till she came to herself, and comforted her with *loving* words.

Esther xv. 8.

Shall I come unto you with a rod, or in *love*, and in the spirit of meekness?

1 Cor. iv. 21.

The one preach Christ of contention, but the other of *love*.

Phil. i. 17.

Great pity was it, as it thought hem alle,

That ever swiche a chance shulde befallle,

For gentilmen they wer of grit estat,

And nothing but for *love* was this debat.

Chaucer. Cant. Tales.

Hearken to the birds *love*-learned song,

The dewie leaves among! *Spenser's Epithalamium.*

Good shepherd, tell this youth what 'tis to *love*.

—It is to be made all of sighs and tears;

It is to be made all of faith and service;

It is to be all made of fantasy,

All made of passion, and all made of wishes,

AH adoration, duty, and obedience;

*All humbleness, all patience, all impatience,

All purity, all trial, all observance. *Shakespeare.*

Demetrius

Made *love* to Nedar's daughter Helena,

And won her soul. *Id. Mids. Night's Dream.*

If you will marry, make your *loves* to me,

My lady is bespoken. *Id. King Lear.*

He is not lolling on a lewd *love* bed,

But on his knees at meditation. *Shakespeare.*

Come, *love* and health to all!

Then I'll sit down: give me some wine; fill full. *Id.*

Lovers say, the heart hath treble wrong,

When it is barred the aidance of the tongue. *Id.*

Have I escaped *loveletters* in the holyday time of

my beauty, and am I now a subject for them? *Id.*

The breast of Hecuba,

When she did suckle Hector, looked not *lovelier*

Than Hector's fore head. *Id. Coriolanus.*

Thou art an old *lovesmonger*, and *speakest* skilfully.

Shakespeare.

Poor Romeo is already dead!

Stabbed with a white wench's black eye,

Run through the ear with a *lovesong*. *Id.*

His *lovesuit* hath been to me

As fearful as a siege. *Id. Cymbeline.*

Away to sweet beds of flowers,

Lovethoughts lie rich when canopied with bowers.

Shakespeare.

So *loving* to my mother,

That he would not let even the winds of heaven

Visit her face too roughly. *Id. Hamlet.*

Fish used to salt water delight more in fresh ; we see that salmon and smelts *love* to get into rivers, though against the stream.

Bacon's Natural History.

The enquiry of truth, which is the *love*-making or wooing of it ; the knowledge of truth, the preference of it ; and the belief of truth, the enjoying of it, is the sovereign good of human nature. *Bacon.*

This earl was of great courage, and much *loved* of his soldiers, to whom he was no less *loving* again.

Huyward.

*Love*song weeds and satyrick thorns are grown,
Where seeds of better arts were early sown. *Donne.*

Other disports than dancing jollities ;

Other *lovetricks* than glancing with the eyes. *Id.*

A *love-sick* brain adores, in romantic strains, the *lovely* idol of his heart, or sighs in real misery at her fancied frowns. *Burton.*

All earthly *love* supposeth some kind of equality, or proportion at least, betwixt the person that *loves*, and is *loved*. *Bp. Hall.*

The good wife is none of our dainty dames, who *love* to appear in a variety of suits every day new ; as if a good gown, like a stratagem in warre, were to be used but once. *Fuller.*

I could not *love*, I'm sure,

One who in *love* were wise. *Cowley.*

Wit, eloquence, and poetry,

Arts which I *loved*. *Id.*

The *love* to sin makes a man sin against his own reason. *Taylor.*

The *love* of God makes a man chaste without the laborious arts of fasting, and exterior disciplines ; he reaches at glory without any other arms but those of *love*. *Id.*

It is no great matter to live *lovingly* with good-natured and meek persons ; but he that can do so with the froward and perverse, he only hath true charity. *Id.*

Love is of two sorts, of friendship and of desire ; the one betwixt friends, the other betwixt lovers ; the one a rational, the other a sensitive *love* : so our *love* of God consists of two parts, an esteeming of God, and desiring of him. *Hammond.*

The flowers which it had pressed

Appeared to my view,

More fresh and *lovely* than the rest,

That in the meadows grew. *Denham.*

What need a vermil-tinctured lip for that
Love-darting eyes, or tresses like the morn ?

Milton.

Love-quarrels oft in pleasing concord end,
Not wedlock treachery, endangering life. *Id.*

When I approached

Her *loveliness*, so absolute she seems,

That what she wills to do, or say,

Seems wisest, virtuousest, discreetest, best. *Id.*

The *love-lorn* nightingale

Nightly to thee her sad song mourneth well. *Id.*

The *lovetale*

Infected Sion's daughters with like heat ;

Whose wanton passions in the sacred porch

Ezekiel saw. *Id. Paradise Lost.*

True *love* is nothing else but goodness exerting itself, in direction toward objects capable of its influence. *Barrow.*

Carrying thus in one person the only two bands of good-will, *loveliness* and *lovingness*. *Sidney.*

The new king, having no less *lovingly* performed all duties to him dead than alive, pursued on the siege of his unnatural brother, as much for the revenge of his father, as for the establishing of his own quiet. *Id.*

Thou lookest

Lovely dreadful. *Otway's Venice Preserved.*

This leaf held near the eye, and obverted to the light, appeared so full of pores, with such a transparency as that of a sieve, a piece of cypress, or *love-hood*. *Boyle on Colours.*

No religion that ever was, so fully represents the goodness of God, and his tender *love* to mankind, which is the most powerful argument to the *love* of God. *Tillotson.*

The Christian religion gives us a more *lovely* character of God than any religion ever did. *Id.*

You know y' are in my power by making *love*. *Dryden.*

The banished never hopes his *love* to see. *Id.*

The *lovely* babe was born with every grace ;

Such was his form, as painters, when they show

Their utmost art, on naked *loves* bestow. *Id.*

'Tis no dishonour, trust me, *love*, 'tis none ;

I would die for thee. *Id. Don Sebastian.*

Let it be never said, that he whose breast

Is filled with *love*, should break a *lover's* rest. *Dryden.*

What danger, Armant, is this your fear ?

Or what *love*secret which I must not hear ? *Id.*

To the dear mistress of my *lovesick* mind,

Her swain a pretty present has designed. *Id.*

Nothing new can spring

Without thy warmth, without thy influence bear,

Or beautiful or *lovesome* can appear. *Id.*

Men in *love* with their opinions may not only suppose what is in question, but allege wrong matter of fact. *Locke.*

To be good and gracious, and a *lover* of knowledge, are suitable things.

Burnet's Theory of the Earth.

Love is the great instrument of nature, the bond and cement of society, the spirit and spring of the universe : *love* is such an affection as cannot so properly be said to be in the soul, as the soul to be in that : it is the whole man wrapt up into one desire. *South.*

The jealous man wishes himself a kind of deity to the person he *loves* ; he would be the only employment of her thoughts. *Addison.*

The children are educated in the different notions of their parents ; the sons follow the father, while the daughters read *love*letters and romances to their mother. *Id. Spectator.*

If there is such a native *loveliness* in the sex, as to make them victorious when in the wrong, how irresistible is their power when they are on the side of truth. *Id.*

Cato's a proper person to entrust

A *lovetale* with. *Id.*

The fair

With cleanly powder dry their hair ;

And round their *lovely* breast and head

Fresh flowers their mingled odours shed. *Prior.*

A *love* potion works more by the strength of charm than nature. *Collier on Popularity.*

He has adapted the arguments of obedience to the imperfection of our understanding, requiring us to consider him only under the amiable attributes of goodness and *lovingkindness*, and to adore him as our friend and patron. *Rogers.*

In youth, of patrimonial wealth possess,

The *love* of science faintly warmed his breast. *Fenton.*

Now I behold the steed curvet and bound,
And paw with restless hoof the smoking ground,
The dew lapped bull now chafes along the plain,
While burning *love* ferments in every vein. *Gay.*

Has this amorous gentleman presented himself with any *lovetoy*s, such as gold snuff-boxes ? *Arbuthnot and Pope.*

Let mutual joys our mutual trust combine,
And *love*, and *love-born* confidence be thine.

Pope.

The *lover* and the *love* of human kind.

Id.

Sae wistfully she gazed on me,

And *lovelier* was than ever:

Quo' she, a sodger ance I *lov'd*,

Forget him shall I never.

Burns.

What is life when wanting *love*?

Night without a morning:

Love's the cloudless summer sun,

Nature gay adorning.

Id.

That *love* of praise can never be criminal, that excites and enables a man to do a great deal more good than he could do without it.

Mason.

Love is not pedlar's trumpery bought and sold:

He will give freely, or he will withhold;

His soul abhors a mercenary thought,

And him as deeply who abhors it not.

Cowper.

Prospects, however *lovely*, may be seen

Till half their beauties fade.

Id.

Oh! ever *loving*, *lovely*, and beloved;

How selfish sorrow ponders on the past,

And clings to thoughts now better far removed!

But Time shall tear thy shadow from me last.

Byron.

Thou *lovedst* me

Too much, as I *loved* thee: we were not made

To torture thus each other, though it were

The deadliest sin to *love* as we have *loved*.

Id.

Here is a *loveliness* in death,

That parts not quite with parting breath:

But beauty with that fearful bloom,

That hue which haunts it to the tomb;

Expression's last receding ray,

A gilded halo hovering round decay,

The farewell beam of feeling past away!

Id.

LOUGH, *n. s.* Sax. *luh*, *lagu*; Goth. *laug*; Teut. *luch*; Irish *loch*. A lake or body of standing water.

A people near the northern pole that won,
Whom Ireland sent from *loughs* and forests hore,
Divided far by sea from Europe's shore. *Fairfax*.
Lough Ness never freezes.

Philosophical Transactions.

LOUGHBOROUGH, a market town of Leicestershire, the second in the county. In the time of the Saxons it was a royal village. The chief manufactures are stockings, and cotton-spinning. The district of Charnwood Forest, westward of the town, extends ten miles in length, and six in breadth. It is full of hills, woods, and rocks, and was disforested by Henry III. Its market is on Thursday; and its fairs are on April 25th, May 28th, August 1st, and November 2d. It has a large church, a free school, and two charity schools for eighty boys, and twenty girls. It has been much reduced by fires; but is still a very agreeable town, and is seated on the Fosse, which runs almost parallel with the Soar. The new canal has made its coal trade very extensive. It is eleven miles north of Leicester, and 109 north-west by west of London.

LOUGH NEAGH. See NEAGH.

LOUGH STRANGFORD. See STRANGFORD.

LOUIS, or LEWIS, the name of eighteen kings of France. See FRANCE. Of these we shall here only take notice of the following:—

LOUIS VII., A. D. 1137, was the first who had the courage to oppose the encroachments of the popes on the regal authority: pope Innocent II.

excommunicated him for appointing an archbishop of Bourges; but Louis defended his prerogatives, and put the priests to death who had been the authors of the quarrel. In 1147 he marched with an army of 80,000 men against the Saracens, but was defeated; and, returning by sea, was taken by the Greeks, but rescued by Roger king of Sicily. He died in 1180, aged sixty.

LOUIS IX., or St. LOUIS, one of the greatest monarchs of France; equally memorable for his valor and his virtues, but unfortunately, misled by the superstition of the times, he sacrificed his own repose, and the welfare of his kingdom, to the folly of crusading. He succeeded his father in 1226. In 1248, leaving France to the care of his mother, he embarked for Egypt, attended by his queen, his three brothers, and the flower of the French nobility. At first his victories were rapid; he took Damietta in 1249; but in 1250 was defeated and taken prisoner by the Turks, with all his nobles, and the greatest part of his army. The sultan demanded an exorbitant sum for his ransom, and his answer deserves to be recorded: 'Tell the sultan, that a king of France is not to be ransomed with money; I will give the sum required for my people, and Damietta for myself.' These terms were accepted, and a peace of ten years ensued. Upon his return to France, he diminished the taxes, revoked those which the financiers had introduced; issued several salutary edicts; founded several churches and hospitals; and effectually overturned the ecclesiastical jurisdiction of the court of Rome, by his Pragmatic sanction in 1269, which established the independency of the Gallican church. Thirteen years residence in his capital indemnified his subjects for his absence; but his pious zeal prevented the enjoyment of this happiness: he embarked for the sixth crusade in 1270; and died the same year, at the siege of Tunis, aged fifty-five. See FRANCE.

LOUIS XII. A. D. 1492, styled the Just, and the father of his people, is memorable for his valor in the field, and his wisdom in the cabinet. He was undoubtedly a great general, though unfortunate towards the end of his reign, when he did not command his troops in person: his orders transmitted from home were misunderstood, or wilfully disobeyed; and he had the mortification, before he died, to see the total expulsion of the French from the possessions he had acquired for them by his personal bravery. At fifty-three years of age he married the princess Mary of England, sister of Henry VIII. and died about two months after his nuptials, in 1515.

LOUIS XIII., A. D. 1610, increased the military reputation of his country, and made considerable additions to its domains. The beginning of his reign was occupied in civil wars with his mother and his protestant subjects; which he was excited to continue by his celebrated minister cardinal Richelieu, who attended him to the siege of Rochelle, the bulwark of the Hugonot party; which surrendered in 1628, after a siege of more than a year. Upon this and other occasions the king gave proofs of great personal bravery. His attachment to his ally the duke de

Nevers, who succeeded to the duchy of Mantua, but was refused the investiture by Charles VI. emperor of Germany, involved him in a war with that prince, the Spaniards, and the duke of Savoy; in which Louis was victorious; and obtained a treaty of peace, by which the duke of Mantua was guaranteed in the possession of his dominions. In 1635 a new war broke out between France and Spain, and the emperor took part with the latter: it lasted thirteen years against the emperor, and twenty-five against Spain, with various success; and the military experience acquired by the different armies in the Low Countries, on the frontiers of France, and in Italy, paved the way for the successes of Louis XIV. Louis XIII. died in 1643, aged forty-one.

Louis XIV., falsely styled the Great, became king at five years of age, in 1643. He was at first styled Dieu-donne, the French considering him as the gift of heaven, granted to their prayers after the queen had been barren twenty-two years. This princess (Anne of Austria) was declared regent by Louis XIII., and saw herself under necessity of continuing the war against Philip IV. king of Spain, her brother. The duke d'Enghien was made general of the French armies; and so signal was the success of this renowned warrior (afterwards prince of Condé), that his victories brought on the advantageous treaty of Munster in 1648, between France, the emperor Ferdinand III. and Christina queen of Sweden: the basis of the aggrandisement of France in this reign, the principal events of which, and of the next, will be found related under the articles GREAT BRITAIN, FRANCE, &c. Louis XIV. died in 1715, aged seventy-seven.

Louis XV., great-grandson of the preceding, succeeded in 1715. He was styled, in the course of his reign, the well beloved, which he lost some years before he died, and was detested and despised by his subjects for his shameful attachment to Madame Pompadour, the wife of M. D'Etoiles, who, by the ministry of her patron the duke d'Aiguillon, governed the kingdom, and invaded the rights of the people. He died in 1774, in the sixty-fourth year of his age, and fifty-ninth of his reign.

Louis XVI., one of the most unfortunate, and yet one of the most deserving of the French monarchs of the race of Capet, and house of Bourbon, succeeded his grandfather in 1774. The principal events of this reign are related under the article FRANCE. His character is universally allowed to have been such as, in times of less disturbance, would have insured him a high degree of popularity to the end of his life. He was naturally of a mild and humane disposition; and had the merit of having been the first who instituted a society for the instruction and employment of the blind; an example of benevolence which has been since successfully followed in this and other countries. He was also an author, and translated 5 vols. of Gibbon's History, and Walpole's Historical Doubts, into French. His last will and testament, written by himself, exhibits a strong picture of his piety, resignation, and affection for his relations. At his trial he showed an uncommon degree of spirit, recol-

lection, and undaunted fortitude. On the 21st of January, 1793, this unfortunate monarch fell by the guillotine, a sacrifice to that democratic jealousy,—that popular fury,—which only exhausted its rage by destroying many of the greatest men in France.

LOUIS XVIII. (Stanislaus Xavier de France), second son of the dauphin, the son of Louis XV., and brother of the unfortunate Louis XVI., was born at Versailles, November 17th, 1755. He is said as a boy to have manifested a timid and reserved disposition, united with a more decided turn for literary pursuits than either of his brothers. On the accession of his elder brother to the throne, he presented him with a pamphlet of his own writing, entitled *Mes Pensées*; which appears to have given but little satisfaction to that prince. The count de Provence, as Louis was then styled, fled from Paris to Coblenz, on the 20th of June 1791, and took a principal share in the organisation of the emigration. The progress of the revolution afterwards compelled him to retire to Turin, and subsequently to Verona, under the name of the count de Lille, a title which he long retained. In 1796 he joined the army of Condé, then at Reigal, and two years afterwards was acknowledged as king of France by the emperor Paul of Russia, at whose invitation he took up his residence in the ducal castle of Mittau in Courland. Soon however he received orders to quit the Russian territories in a week, and took refuge at Warsaw, whence the king of Prussia finally compelled him to retire, as a last resource, to England. Here he was hospitably received and provided for at Hartwell, a seat belonging to the marquiss of Buckingham, where he remained till the fall of Napoleon in 1814; when he was publicly received in London as king of France. Again driven from his throne, by the return of Buonaparte from Elba, he retired into the Netherlands, till the battle of Waterloo. He survived this second elevation nine years, and died in his sixty-ninth year, on the 16th of September, 1824. For a considerable time previously, a dry erysipelas in his legs had deprived him of the power of walking, and, together with a natural tendency to corpulency, produced a paralysis of the lower extremities which became the immediate cause of his dissolution. This prince acted with great temper and policy on his second return to France, when it required no small skill to render the intrusion of the foreign armies palatable to the people. Besides the pamphlet already mentioned, he was the author of *Le Mariage Secret*, a comedy in three acts, in which he is reported to have been assisted by his secretary Ducis, the imitator of Shakspeare. Two operas also were the offspring of his pen, *Panurge*, and the *Caravane du Caire*, to which Gretry composed the music. His other writings are an account of his journey to Coblenz, and a few political articles in the *Journal de Paris*, during the year 1814.

LOUIS (St.), a city of Brasil, South America, the chief town of the island of Maranhão. It is the see of a bishop, and built upon very unequal ground, extending from the water's edge, to the distance of about a mile and a half. It comprises some broad streets and squares, but is

a very straggling place. This, however, gives it an airy appearance in so warm a climate; the streets are mostly paved, and the houses are many of them neat, but in the smaller streets the windows are not glazed. The churches are numerous, and gaudily decorated; there are also Carmelite and Franciscan convents. The governor's palace stands upon rising ground, fronting the town, and is a long stone building, like most of the rest, of one story only in height. The western end joins the town-hall and prison, and the oblong piece of ground in its front, covered with grass, gives to it on the whole a handsome and striking appearance. There is a fort in the adjoining hollow close to the water; the other extremity is nearly closed by the cathedral. The ground upon which the whole place stands is said to be composed of a soft red stone. This city also contains a custom-house and treasury. The harbour is formed by a creek in the island, and entered from the bay of St. Marcos. The channel is narrow but of sufficient depth for common sized merchant ships. Population, including negroes, about 12,000. Long. $43^{\circ} 37' W.$, lat. $2^{\circ} 30' S.$

LOUIS (St.), a lake of North America, twelve miles long, by six broad; formed at the junction of the Ottawa with the St. Lawrence.

LOUIS (St.), a river of North America, navigable 150 miles, which has its source near the head waters of the Mississippi, and falls into Lake Superior, on the west shore. Long. $91^{\circ} 52' W.$, lat. $46^{\circ} 44' N.$

LOUIS (St.), a river of Lower Canada, which falls into the St. Lawrence, where its waters form Lake St. Louis.

LOUIS D'OR, a French coin first struck in the reign of Louis XIII. in 1640, but laid aside at the revolution. Its original value was twenty-four francs, 20s. English. A new Louis d'or of twenty francs is now current, and its value, at par, is 16s. 8d. English.

LOUIS, FORT, a barrier fortress in the north-east of France, in Alsace. It is situated on the island of Giessenheim, on the Rhine, and was constructed by the famous Vauban. In November 1793 it was taken by the Austrians, who blew up the works: but the French soon after restored them. Twelve miles east of Haguenau.

LOUIS, FORT, a French settlement near the mouth of the Coza in Florida, sixty miles north-east of the mouth of the Mississippi. It was the residence of the governor of Louisiana, till the peace in 1673.

LOUIS, KNIGHTS OF ST., a military order in France, instituted by Louis XIV. in 1693. The annexed diagram represents the cross of this order; the king was their grand master; and there were in it eight great crosses, and twenty-four commanders; the number of knights was not limited. At their institution, the king charged his revenue with a fund of 300,000 livres for the pensions of the commanders and knights.

LOUISA, a county in the centre of Virginia, North America, bounded north by Orange and Spotsylvania counties, east by Hanover county, south by Goochland and Fluvanna counties, and west by Albemarle county: 116 miles from Washington.

LOUISA, LOANGO, a large river of Loango, in Western Africa, which falls into the Atlantic, in lat. $5^{\circ} 30' S.$ Captain Tuckey found only one river here bearing this name, though two have been generally laid down in the maps.

LOUISBURG, the capital of Cape Breton, is situated on a point of land on the south-east side of that island. Its streets consist for the most part of stone houses, regularly built, with a large parade at a little distance from the citadel; the inside of which is a fine square, whose sides measure 200 feet. The town is about half an English mile in length, and two in circuit. It has an excellent harbour, four leagues deep, and fit for the largest fleets, but it is closed by ice from November to May. The entrance is but 400 yards wide, between two islands, one of which is fortified, and its fires cross with those of batteries on the main. In the north-east part is a fine careening wharf to heave down; and very secure from all winds. On the opposite side are fishing stages, for 2000 boats to cure fish. Sometimes the frosts set in soon, and are more intense; as particularly in 1745, when by the middle of October a great part of the harbour was frozen.

The principal trade here is the cod fishery, which may in general be continued from April to the end of the year. Louisburg was taken from the French by the English under Sir Peter Warren and our American forces, commanded by Sir William Pepperel, in the year 1745; but afterwards restored to France by the treaty of Aix-la-Chapelle. It was retaken by the English, under admiral Boscawen and lieutenant-general Amherst, on the 27th of July 1758, and its fortifications demolished. Long. $59^{\circ} 50' W.$, lat. $45^{\circ} 55' N.$

LOUISIADE, an archipelago of islands in the Eastern Seas, lying to the south-east of New Guinea, and about 400 miles in length, by 160 in extreme breadth. The centre of them is nearly under 10° of S. lat. and $152^{\circ} 25'$ E. long. They are interspersed with dangerous shoals and reefs, the principal of which received names from the French in 1793, in the voyage in quest of La Perouse. Some of the islands are fertile and populous, the inhabitants being of a deep copper color, with woolly hair; and wearing a cord wound several times round their middle. Many smear their faces with charcoal, and use personal ornaments. They are fond of war, and fight with slings, darts, tomahawks, and a large wooden shield. There seems reason to conclude that they are cannibals; and the French found them of a perfidious disposition; their canoes have both outriggers and sails. Their huts stand six or eight feet from the ground on posts; one of their canoes was thought by the navigators who visited them to be fifty feet long. They appear to set little value on iron. None of the islands composing this archipelago exceed thirty-five miles in length.

LOUISIANA, a country ceded to the United States of America by France in 1805, for 15,000,000 dollars, is bounded north by unsettled country. The northern part of the eastern boundary is formed by Red River, a branch of the Assiniboine, which rises near the sources of the Mississippi. The boundary line, proceeding south to the sources of the Mississippi, follows that river down to lat. 31° N., thence proceeds due east to the Perdido, thence down that stream to its mouth. The gulf of Mexico forms the south boundary; the Spanish provinces form a part of the west and south-west, and the Pacific Ocean the north part of the west boundary. Long. 89° to $126^{\circ} 30'$ W., lat. 26° to $49^{\circ} 37'$ N. From north to south, about 1380 miles, and from east to west 1680; containing about 1,500,000 square miles.

The boundaries of this country are not accurately defined, and its extent not well ascertained. Spain maintains that it extends no farther east than the outlet of Lake Pontchartrain, and no farther west on the gulf of Mexico than the Sabine River; but the government of the United States claims to the Del Norte, including the province of the Texas. The claim of the United States to the country watered by the Columbia and its branches, lying between the Rocky Mountains and the Pacific Ocean has also been contested.

A small portion of this country is incorporated into the state of Mississippi, the south-east part forms the state of Louisiana, and the remainder is formed into a government by the name of Missouri Territory. But a very small part of this immense territory is yet purchased of the natives. It embraces a great variety of climate, soil, and productions. The face of the country is very various; towards the south it is level, and in many parts overflowed; towards the north elevated and hilly; and towards the west abounding in lofty mountains. The principal mountains are the Rocky Mountains.

West of the Rocky Mountains the principal rivers are the Columbia and its branches, the Multnomah, Lewis's River, and Clark's River. The principal rivers east of the Rocky Mountains are Missouri, Osage, Bighorn, La Platte, Kansas, Yellowstone, Arkansas, Red River, White River, St. Francis, Ouachitta, Moines, St. Peter's, Sabine, Brassos de Dios, Colorado, Guadalupe, and Del Norte. See MISSOURI and TEXAS.

LOUISIANA, one of the United States formed in 1812, is bounded north by Missouri Territory; east by the state of Mississippi and the gulf of Mexico. The boundary line is formed by the river Mississippi from lat. 33° to 31° N., thence by the parallel of 31° to Pearl River, thence by that stream to its mouth. The gulf of Mexico forms the southern boundary, and Sabine River the western, from its mouth to lat. 32° N.; thence the boundary line proceeds due north to lat. 33° , thence due east to the Mississippi, Long. 89° to $94^{\circ} 5'$ W., lat. 29° to 33° N.; 240 miles long from north to south, and 210 broad, containing 48,220 square miles. The number of militia in 1817 amounted to 9233.

At the time of the census, in 1810, this state was styled the territory of Orleans, and contained

twelve districts, and 75,556 inhabitants, of whom 31,660 were slaves. Since that time it has been erected into a state, with the annexation of a part of West Florida, containing the parishes of New Feliciana, East Baton Rouge, St. Helena, and St. Tammany.

The parishes, square miles, and population, in 1810, are exhibited in the following Table:—

Parishes.	Square miles.	Population.
Ascension . . .	350	5100
Assumption . . .	500	5670
Avozelles . . .	700	3488
Baton Rouge, (West) . . .	350	3092
Concordia . . .	2100	4662
Iberville . . .	350	7050
Interior of La Fourche . . .	2500	5500
Natchitoches . . .	10600	7926
Quachitta . . .	4000	5140
Ocatatoola . . .	2000	2576
Orleans . . .	1300	46,310
Plaquemines . . .	1500	4489
Point Coupee . . .	600	5936
Rapides . . .	2300	7559
St. Bernard . . .	400	3356
St. Charles . . .	300	5107
St. James . . .	170	7672
St. John Baptiste . . .	150	5700
St. Landre, Opelousas . . .	7600	12,552
St. Mary's and St. Martin's, } Attacapas . . . }	5100	13,646
Baton Rouge, (East) . . .	6717	10,000
New Feliciana . . .	8247	
St. Helena . . .	4027	
St. Tammany . . .	2861	
Washington . . .	2286	

New Orleans is the capital, and the only large town. The most considerable towns west of the Mississippi, are Natchitoches, St. Martinsville, and Alexandria. There are five banks in this state, all at New Orleans. The legislature is composed of a senate of seventeen members, and a house of representatives, of thirty-four members. In 1818 eight of the senators, and twenty-one of the representatives were French: and the others Americans. A large proportion of the inhabitants are French and Spanish. The principal rivers are the Mississippi, Red, Quachitta, Black, Tensas, Sabine, Calcasieu, Mermentau, Vermilion, Atchafalaya, Teche, Pearl, Amite, and Iberville. The largest lakes are Pontchartrain, Maurepas, Borgne, Chetimaches, Mermentau, Calcasieu, Sabine, Bisteneau, Bodeau, and Ocatatoola.

All the southern part of this state is of warm temperature, and a vast alluvial tract of low champaign country, extending from Lake Borgne to Sabine River, and from the gulf of Mexico to Baton Rouge and Red River, about 250 miles long, and from seventy to 140 wide. This extensive tract is intersected by numerous rivers, bays, creeks, and lakes, dividing the country into a great number of islands. The country about

the Balize is one continued swamp, destitute of trees, and covered with a species of coarse reeds, from four to five feet high. Nothing can be more dreary than a prospect from a ship's mast while passing this immense waste.

A large extent of country in this state, is annually overflowed by the Mississippi. According to Mr. Darby, the average width of overflowed lands above Red River, from lat. 31° to 32° N., may be assumed at twenty miles, equal to 2770 square miles. Below lat. 31° to the efflux of the La Fourche, about eighty miles in extent, the inundation is about forty miles in width; equal to 3200 square miles. All the country below the efflux of the La Fourche is liable to be inundated equal to 2370 square miles. From this calculation it appears that 8340 square miles are liable to be inundated by the overflowing of the Mississippi; and if to this be added 2550 square miles, for the inundated lands on Red River, the whole surface of the state, liable to inundation, will amount to 10,890 square miles. Of this extent, not one-half is actually covered annually with water. The immediate banks of all the streams are seldom, and many of them never, inundated; and they afford strips of rich tillable land, from a mile to a mile and a half wide.

The country between the Mississippi, Iberville, and Pearl Rivers, is an important part of the state. The southern half is a level country, yet highly productive in cotton, sugar, rice, corn, and indigo. The northern part, presents an undulating surface, covered with a heavy growth of timber, consisting of white, red, and yellow oak, hickory, black walnut, sassafras, magnolia, and poplar. The district of New Feliciana has been considered by some as the garden of Louisiana.

The south-western part of the state, comprising the districts of Opelousas and Attacapas, consists mostly of extensive prairies. Some of these prairies are detached, but the lines of woods between them are generally very narrow; and they may be considered as forming one immense meadow. A large portion of these tracts are barren; but some parts, particularly that bordering on the Teche, are very fertile, and contain flourishing settlements. It has been estimated, that the prairie lands in the state, including the swamps along the gulf of Mexico, constitute one-fifth of its whole surface.

The country on both sides of Red River, from its mouth to the limits of the state, is intersected with lakes, which are more than forty in number, and all communicate with the river. The bottoms on the river are from one to ten miles wide, and of very fertile soil. The timber on the bottoms is willow, cotton woods, honey locust, &c.; on the rich uplands, elm, ash, hickory, mulberry, walnut, and grape-vine; on the sandy uplands are pitch and yellow pines, and oak. The staple productions are cotton, sugar, and rice.

LOUISVILLE, a town of Kentucky, United States, the capital of Jefferson county; it is pleasantly situated on the Ohio, at the head of the Rapids, being built on an eminence seventy feet high, and gently descending to a narrow plain. The principal streets run parallel with the river. A company has been incorporated here by the legislature, for the purpose of opening a

canal on the Kentucky side of the Rapids. An extensive commerce is now carried on from this town with Natchez, New Orleans, and St. Louis. It is a flourishing town, and has two banks, an academy, and excellent rope walks: 122 miles from Cincinnati, and fifty-two west of Frankfort. Inhabitants about 10,000.

LOUNGE, *v. n.* } Belg. *lunderen*; Teut. *Lounger*, *n. s.* } *Slungeren*. To linger; idle away time; live or behave lazily.

The *loungeurs* are satisfied with being merely part of the number of mankind, without distinguishing themselves from amongst them. They may be said rather to suffer their time to pass than to spend, it without regard to the past, or prospect of the future.

Spectator.

LOUR, or } Belg. *looren*; Teut. *Low'er*, *v. n. & n. s.* } *lauren*, to frown. To LOW'ERINGLY, *adv.* } look dark or gloomy; applied to the appearance of the sky as well as countenance; to pout; look sullen: as a substantive, gloominess; sourness of look.

Now is the winter of our discontent

Made glorious summer by this sun of York,
And all the clouds that *lowered* upon our house,
In the deep bosom of the ocean buried.

Shakspeare.

There was Diana when Actæon saw her, and one of her foolish nymphs, who weeping, and withal *lowering*, one might see the workman meant to set forth tears of anger.

Sidney.

Philoclea was jealous for Zelmane, not without so mighty a *lower* as that face could yield.

Id.

He mounts the throne, and Juno took her place,
But sullen discontent sat *lowering* on her face;
Then impotent of tongue, her silence broke,
Thus turbulent in rattling tone she spoke.

Dryden.

The *lowering* spring, with lavish rain,
Beats down the slender stem and bearded grain.

Id.

When the heavens are filled with clouds, and all nature wears a *lowering* countenance, I withdraw myself from these uncomfortable scenes.

Addison.

If on Swithin's feast the welkin *lours*,
And every penthouse streams with hasty showers,
Twice twenty days shall clouds their fleeces drain.

Gay.

Their *lowering* and pouring,

The storm no more I dread;

Though thickening and blackening

Round my devoted head.

Burns.

Ask what is human life—the sage replies,

With disappointment *louring* in his eyes,

A painful passage o'er a restless flood,

A vain pursuit of fugitive false good,

A scene of fancied bliss and heart-felt care,

Closing at last in darkness and despair.

Cowper.

Above, the frequent feudal towers

Through green leaves lift their walls of grey

And many a rock which steeply *lours*,

And noble arch in proud decay,

Look o'er this vale of vintage-bowers.

Byron.

LOURISTAN, a mountainous but fertile district of Irak, in Persia, bordering upon Khuzistan. It is abundantly watered, and this pasture is most luxuriant; but agriculture is quite neglected. The pastoral tribes of the country trace their origin to a remote antiquity, though they admit that their ancestors have become mingled with several Turkish hordes. They are savage, fearless, and nearly independent. They reside

even through the winter in black tents. The only town is Korumabad.

LOUSE, *n. s. & v. a.*

LOUS'ILY, *adv.*

LOUS'INESS, *n. s.*

LOUS'Y, *adj.*

learned company; à Gr. λυω, λυσω, he says, i. e. solvo, nati enim in cute eam erodunt. A body insect of the genus pediculus: to louse is, oddly enough, used by some of our quaint writers for to free from lice: lousy, for mean; low-born: in a mean, paltry way.

There were lice upon man and beast.

Erod. viii. 18.

As for all other good women, that love to do but little work, how handsome it is to louse themselves in the sunshine, they that have been but a while in Ireland can well witness.

Spenser on Ireland.

I pray you now, remembrance on the lousy knave, mine host.

—A lousy knave, to have his gibes and his mockeries.

Shakespeare.

Frogs, lice, and flies, must all his palace fill

With loathed intrusion.

Milton.

Let him be daubed with lace, live high and whore, Sometimes be lousy, but be never poor.

Dryden.

Sweetbriar and gooseberry are only lousy in dry times, or very hot places.

Mortimer's Husbandry.

It is beyond even an atheist's credulity and imprudence to affirm, that the first men might proceed out of the tumours of trees, as maggots and flies are supposed to do now, or might grow upon trees; or perhaps might be the lice of some prodigious animals, whose species is now extinct.

Bentley.

Not that I value the money the fourth part of the skip of a louse.

Swift.

You sat and loused him all the sun-shine day.

Id.

LOUSE, in zoology. See PEDICULUS.

LOUT, *v. n., v. a. & n. s.*

LOUT'ISH,

LOUT'ISHLY, *adv.*

To bow; to stoop; stoop awkwardly: hence a low servile, clownish fellow. Shakespeare uses the active verb for to overpower or over-influence, or perhaps, circumvent.

He fond this holy old Urban anon

Among the saintes buriels louting.

Chaucer. Cant. Tales.

He fair the knight saluted, louting low,

Who fair him quitted, as that courteous was.

Spenser.

This lout, as he exceeds our lords, the odds

Is that we scarce are men, and you are gods.

Shakespeare.

I have need of such a youth,

That can with some discretion do my business;

For 'tis no trusting to yon foolish lout.

Id.

I am louted by a traitor villain,

And cannot help the noble chevalier.

Id.

The palmer, grey with age, with countenance louting low,

His head even to the earth before the king did bow.

Dryden.

Under the sand bag he was seen,

Louting low, like a forester green.

Ben Jonson.

Pamela, whose noble heart with disdain, that the trust of her virtue is reposed in such a lout's hands, and yet, to shew an obedience, taken in shepherdish apparel.

Sidney.

This loutish clown is such, that you never saw so

illfavoured a visor; his behaviour such, that he is beyond the degree of ridiculous.

Sidney.

Thus wailed the louts in melancholy strain.

Gay.

If after all some headstrong hardy lout Would disobey, though sure to be shut out, Could he with reason murmur at his case, Himself sole author of his own disgrace?

Cowper.

LOUTH, a market town of Lincolnshire, one of the handsomest in the county. It contains about 4000 inhabitants; and has a canal to the sea at Tilney, about eight miles long, a charity school for forty children, and a free school founded by Edward IV., together with a large church, and a fine steeple, 288 feet high. The other public buildings are the town-hall, the mansion-house, the assembly room, the theatre, and several dissenting meeting-houses. The principal manufactures are those of carpets and blankets. The town is incorporated under a warden and six assistants. It has markets on Wednesday and Saturday, and fairs on May 24th and August 16th. It is twenty-seven miles north-east of Lincoln, and 148 north of London.

LOUTH, a county in the province of Leinster, and kingdom of Ireland, bounded on the north by the counties of Monaghan and Armagh, on the south by Meath, on the east by the Irish Channel, and on the west by Cavan. It extends twenty-three miles in length, and sixteen in breadth. Its area contains 110,750 acres, which are divided amongst sixty-one parishes, and five baronies, these are called Ardee, Dundalk Baronies, Upper and Lower Ferrand, and Louth. Its chief towns are Dundalk, the Assizes town, Ardee, Carlingford, remarkable for its beds of excellent oysters; Dunleer; Castle-Bellingham, famous for its malt liquor; Louth; and Callon, the beautiful and improved residence of the right honorable lord Oriel, to whom it owes its origin, as well as its present condition. Besides these, part of the county of the town of Drogheda is properly in this county (see DROGHEDA), the Boyne being the natural boundary between Meath and Louth.

The surface of Louth is singularly undulating and well watered, and the soil remarkably fertile. Much corn is grown here, for which there is an immediate sale at Drogheda; and good coarse linen was formerly manufactured throughout the county, but this trade has passed out of this district into Yorkshire. This county abounds in military and ecclesiastic antiquities; and many ancient raths or artificial mounds, generally attributed to the Danes, exist here (vide Wright's Louthiana), besides numerous beautiful monastic ruins. The sea-coast affords some advantages of exportation, but might be made to yield still greater. Carlingford Bay is more serviceable to the adjacent county than to Louth. Dundalk Bay is much in want of improvement; and the trade of Drogheda would be multiplied tenfold, by a small expense in deepening the mouth of the river. The town of Louth, in the same county, contains only a population of 600 persons. Here are the ruins of an ancient abbey, founded by St. Patrick; the possessions of which, at the general dissolution, were granted to Sir

Oliver Plunket, whose descendants now enjoy the title of barons of Louth.

LOUVAIN, a city of the Netherlands, on the river Dyle, in the old province of Austrian Brabant. The walls are nine miles in circumference, but not above a third part of the ground is built on, the rest being laid out in gardens, fields, and vineyards. The castle stands on a high hill, surrounded with fine gardens, and has a charming prospect. The town contains nine market places, 126 streets, sixteen stone bridges, numerous water mills, and several handsome palaces. The town-house is a venerable Gothic building, adorned with statues on the outside; and the churches are handsome, particularly the collegiate church of St. Peter; but the principal ornament is the university, founded in 1426 by John IV. duke of Brabant. It contains about forty colleges, among which are four called *Pædagogia*; and an English college of friars, preachers, established by cardinal Howard, brother to the duke of Norfolk, who was originally chaplain to queen Catharine, consort to Charles II. The Irish have likewise a seminary, erected in part under the care of Eugenius Mattheus, titular archbishop of Dublin, 1623. In 1743 the inhabitants amounted to 12,000. At the beginning of the fourteenth century, under John III., Louvain had a flourishing manufacture of woollen cloth: 400 houses being occupied by substantial clothiers, who employed an incredible number of weavers. In 1382 these weavers took up arms, and rebelled against duke Wenceslaus, throwing from the windows of the town-hall seventeen of the aldermen and counsellors, and afterwards proceeded to lay waste great part of Brabant; but being besieged, and reduced to great extremities, they implored mercy, which was granted after the execution of several of the ring-leaders. But the greater part took refuge in England; where they introduced, or at least improved, the woollen manufacture. From that period the manufacture declined, and little or no cloth of any account is now made. Upon the ruins of these looms was also formed the cloth manufacture of Limbourg, which is still carried on with advantage. The old draper's hall is now converted into public schools, where lectures in divinity, philosophy, law, and physic, and the public acts are made. Adjoining to these is the university library.

Louvain was anciently the capital of the province. It has often been besieged, but seldom taken. In 1542 it was besieged by the Gueldians; in 1572 by William, prince of Orange; in 1635 by the Dutch and French united; and in 1710 by the French; but on all these occasions the enemy were obliged to retire with loss. In 1746, however, it was taken by the French; and again in 1792 by the French republicans under Dumourier, but evacuated on the 22d of March, 1793. It was at last retaken and long annexed to the republic in 1794. Population 25,000. It lies fourteen miles north-east of Brussels, and twenty-one south-east of Antwerp.

LOUVETURE (Toussaint), a negro chief, who by his intelligence, bravery, and activity, had nearly accomplished the independence of St. Domingo. In 1796 general Rochambeau

confided to him the command of a division of the French army, destined to oppose the English, and from this period he appears to have conceived a project of becoming independent. He expelled from the island the French commissary Santhonax, and proceeded with great artifice towards the execution of his designs. In 1799 the colony became the prey of intestine divisions, and a civil war took place between Toussaint and the mulatto general Rigaud, in which the former proved triumphant. On the accession of Buonaparte, this negro chief, by alternate submission and hostility, endeavoured to secure his authority, until, at length, general Leclerc, with a French fleet and army, in February 1801, put an end to his temporising policy: after a short but brave resistance, he was compelled to submit. He was now transported to France, and confined, first in the temple at Paris, and then in the fortress of Joux, where he died in 1803, not without suspicion of violence being used.

LOUVET (John Baptist), a celebrated French senator, and literary character, a considerable sufferer during the course of the most bloody part of the French revolution. From an interesting sketch of his life, written by himself in the caverns of Jura in 1794, and published in 1795, our limits permit us only to select the few following particulars:—He passed most of his time in the country, composing works of literature; and his love of independence had led him to banish luxury so completely, that 800 francs per annum (about £34 sterling) sufficed for his maintenance. The first seven volumes of his first work, *The Adventures of the Chev. de Faublas*, increased his income; and the publication of six more, in spring 1789, added to it still farther. But the profits of his next novel were diminished by the revolution, which, by the demand it occasioned for political writings, stifled the taste for frivolous pieces. Mounier having in October, 1789, published a pamphlet, accusing the Parisians of the crimes of the Orleans faction, Louvet wrote an answer, entitled, *Paris Justified*; which was so well received, that he was immediately admitted a member of the Jacobin club, which, however, he but seldom attended. He soon after produced two comedies. In the one, of five acts, entitled *L'Anobli Conspirateur, ou le Bourgeois Gentilhomme du 18me siècle*, he attacked the prejudices concerning nobility. The other was a pointed satire on the mummeries of the court of Rome, entitled *L'Election et L'Audience du Grand Lama Sisipi*. These, however, being thought too bold, were not performed; but his farce entitled *La Grande Revue des armees noires et blanches*, written in ridicule of the army of Coblenz, was represented twenty-five times. In December, 1791, Louvet presented a petition against the princess to the legislative assembly; which, with other two of his petitions, were printed by order of the assembly. In 1792, in the debate respecting a war with Austria, which gave rise to the schism between the Brissotines and Robespierre's faction, Louvet joined the former, reduced Robespierre himself to silence, and from that moment was proscribed by him. Mean time Louvet became editor of the paper called

the Sentinel, of which 20,000 copies were sometimes printed, and in one number of which he attacked the conduct of Dumourier. After the bloody 2d of September he denounced Robespierre, and, had he been supported by Petion, would have prevented the rise of that tyrant's power and the horrors that followed. He, however, published a letter addressed to Maximilian, Robespierre, and his Royalists. On this occasion he was expelled the Jacobin club, together with Roland and other eminent Brissotines. At the trial of Louis XVI. he supported the motion of Salle for an appeal to the people; and not long after was proscribed. After providing for the safety of Lodoiska his wife, and being five weeks secreted by two friends, he left Paris, June 24th; and after passing sometimes for a smuggler, sometimes for a soldier, at other times for a deserter, and at all times for a violent Jacobin or Maratist, and running a thousand risks of being detected, he at last obtained a safe and impenetrable asylum in one of the caverns of Mount Jura; where he remained till the end of July, 1794, when his wife brought him the news of the Thermidorean revolution; soon after which he returned to Paris, was welcomed to his seat by the convention, and not long after elected president. After this he commenced bookseller, but died in 1797.

LOUVRE, the old royal palace at Paris, on the north bank of the Seine, a splendid quadrangular edifice, with a court in the centre, completed by Napoleon. The origin of its name, and the time of the erection of the oldest part of it, are unknown. We only know that Philip Augustus, in 1214, built a fort and a state prison in this place; that Charles V., during the years 1364—80, added some embellishments to the building, and brought his library and his treasury thither; and that Francis I., in 1528, erected that part of the palace which is now called the Old Louvre. Henry IV. laid the foundation of the splendid gallery which connects the Louvre, on the south side, with the Tuileries; Louis XIII. erected the centre; and Louis XIV., according to the plan of the physician Perrault, the elegant façade towards the east, together with the colonnade of the Louvre, which, even now, is the most perfect work of architecture in France. At a later period, Louis XIV. chose the palace built by him at Versailles for his residence. After Napoleon had taken possession of the Tuileries, he began a second gallery, opposite to the former, by which the two palaces would have been made to form a great whole, with a large quadrangular court in the centre; only 600 feet of it were completed at the time of his abdication, and it has not since been continued. Since the revolution, the collection of antiquities has been kept in the lower floor of the Louvre. Here, also, the exhibitions of national industry take place, and the academies hold their sessions.—To have the privilege of the Louvre, formerly meant, in France, a permission to drive, with a coach, into the courts of all the royal palaces. At first, this was the prerogative of the princes only; but, in 1607, when a duke, under the pretence of indisposition, rode into the Louvre, Henry IV. gave him (and, in

1609, the duke of Sully also) permission constantly to do so. At last, during the minority of the king Louis XIII., all the high officers of the crown, and dukes, obtained this privilege from Mary of Medici.

LOUYS, or LOUIS (John), an eminent engraver, who flourished about the middle of the sixteenth century. According to Basin, he was a native of Flanders. He learned the art from Peter Southman, at the time that Suyderhoef studied under him; and his usual style of engraving bears some resemblance to that of his master. One of his best prints is Diana, with her nymphs, reposing after the chase; a middling-sized plate, from Rubens.

LOW, *adj. adv. & v. a.* } Sax. *lēȝþ*; Goth. *lēȝh*; Swed. Teut. *lōw*LAND, } and Belgic *lag*, Dan. *law*, are connected, probably, with the Goth. *la*, LOW'LY, *adj. & adv.* } *leggja*. To lay or deposit. See LAY. LOW'N, *n. s.* } Near the ground; LOW'NESS, } under the ground; LOW'SPIRITED, } deep; depressed; not high or elevated on any scale of admeasurement, rank, price, honor, time, intellect, or sound: hence subdued; impotent; humble; submissive: it is used adverbially in the same variety of signification: the phrases 'low water,' 'low ebb,' clearly relate to the depth of the surface of the water, from the land or some given plane, and not to its shallowness, as Dr. Johnson supposes by defining low, in this sense, 'as not deep.' Swift uses lowed for lowered, barbarously: to lower is to make or bring low: lessen; grow less: lowland is flat, marshy land: lowly and lowliness are used metaphorically only, i. e. for humbly or meanly; humility or meanness: lowly, is an obsolete name of a vessel, or low fellow: lowness is applied both literally and metaphorically in one or other of the senses noted above.

It became a spreading vine of *low* stature.

Ezek. xvii. 6.

Take my yoke upon you, and learn of me: for I am meek and *lowly* in heart.

Matt. xi. 29.

To be worst,

The *lowest*, most dejected thing of fortune,
Stands still in esperance.

Shakspeare.

King Stephen was a worthy peer,
His breeches cost him but a crown,
He thought them sixpence all too dear,
And therefore called the tailor *low*n. *Id.*

They know

By the height, the *lowness*, or the mean, if dearth
Or foison follow. *Id. Antony and Cleopatra.*

Now I must

To the young man send humble treaties,
And palter in the shift of *lowness*. *Shakspeare.*

'Tis better to be *lowly* born,
And range with humble livers in content,
Than to be perked up in a glistening grief,
And wear a golden sorrow. *Id. Henry VIII.*

Moses was a meek man but a severe master; his face did not more shine in God's aspect upon him, than it *lowered* in his aspect to men. *Bp. Hall.*

Vast yellow offsprings are the German's pride ;
But hotter climates narrower frames obtain,
And low-built bodies are the growth of Spain.

Creech.

It will also happen, that the same part of the pipe which was now *lowermost* will presently become higher, so that the water does ascend by descending ; ascending in comparison to the whole instrument, and descending in respect of its several parts.

Wilkins.

Equal in days and nights, except to those
Beyond the polar circles ; to them day
Had unbenighted shone, while the *low* sun,
To recompense his distance, in their sight
Had rounded still the ' horizon, and not known
Or east or west.

Milton.

The *lowest* bottom shook of Erebus.

Id.

So high as heaved the tumid hills, so *low*,
Down sunk a hollow bottom, broad and deep,
Capacious bed of waters.

Id.

His volant touch
Instinct through all proportions *low* and high
Fled and pursued transverse the resonant fugue.

Id.

Yet sometimes nations will decline so *low*
From virtue, which is reason, that no wrong
But justice, and some fatal course annexed,
Deprives them of their outward liberty,
Their inward lost.

Id.

Heaven is for thee too high
To know what passes there ; be *lowly* wise :
Think only what concerns thee, and thy being.

Id.

Above the smook and stir of this dim spot,
Which men call earth, and with *lowthoughted* care,
Strive to keep up a frail and feverish being.

Id.

From the tree her step she turned,
But first *low* reverence done, as to the power
That dwelt within.
There under Ebon shades and *low-browed* rocks,
As ragged as thy locks,
In dark Cimmerian desert ever dwell.

Id.

Eve,

With *lowliness* majestic, from her seat,
And grace, that won who saw to wish her stay,
Rose.

Id. Paradise Lost.

To keep them all quiet, he must keep them in
greater awe and less splendor ; which power he will
use to keep them as *low* as he pleases, and at no
more cost than makes for his own pleasure.

Graunt.

Never the earth on his round shoulders bare,
A maid trained up from high or *low* degree,
That in her doings better could compare
Mirth with respect, few words with curtesy.

Sidney.

As when in open air we blow,
The breath, though strained, sounds flat and *low* :
But if a trumpet take the blast,
It lifts it high, and makes it last.

Waller.

Some people know it is for their advantage to *lower*
their interest.

Child on Trade.

His spirits are so *low* his voice is drowned,
He hears as from afar, or in a swoon,
Like the deaf murmur of a distant sound.

Dryden.

His stile is accommodated to his subject, either
high or *low* ; if his fault be too much *lowness*, that of
Persius is the hardiest of his metaphors.

Id.

My eyes no object met
But *low-hung* clouds, that dipt themselves in rain.
To shake their fleeces on the earth again.

Id.

What a devil is he ?

His errand was to draw the *lowland* damps,

And noisome vapours, from the foggy fens,
Then breathe the baleful stench with all his force.

Id.

The *lowliness* of my fortune has not brought me to
flatter vice ; it is my duty to give testimony to virtue.

Id.

With cries they filled the holy fane ;
Then thus with *lowly* voice Ilioneus began.
As two men were walking by the sea-side, at *low*
water, they saw an oyster, and both pointed at it
together.

L'Estrange.

The blessings of fortune are the *lowest* : the next
are the bodily advantages of strength and health ;
but the superlative blessings, in fine, are those of the
mind.

Id.

Try in men of *low* and mean education, who have
never elevated their thoughts above the spade.

Locke.

In that part of the world which was first inhabited,
even as *low* down as Abraham's time, they wandered
with their flocks and herds.

Id.

The kingdom will lose by this *lowering* of interest,
if it makes foreigners withdraw any of their money.

Id.

Severity, carried to the highest pitch, breaks the
mind ; and then, in the place of a disorderly young
fellow, you have a *lowspirited* moped creature.

Id.

Who can imagine that in sixteen or seventeen
hundred years time, taking the *lower* chronology that
the earth had then stood, mankind should be propa-
gated no farther than Judæa ?

Burnet.

The name of servants has of old been reckoned to
imply a certain meanness of mind, as well as *lowness*
of condition.

South.

Lucia, speak *low*, he is retired to rest.

Addison.

He has not so many thoughts that are *low* and
vulgar, but, at the same time, has not so many
thoughts that are sublime and noble.

Id.

The theatre is so well contrived, that, from the
very deep of the stage, the *lowest* sound may be heard
distinctly to the farthest part of the audience ; and
yet, if you raise your voice as high as you please,
there is nothing like an echo to cause confusion.

Id. on Italy.

In Gothic cathedrals, the narrowness of the arch
makes it rise in height, the *lowness* opens it in
breadth.

Addison.

Though he before had gall and rage,
Which death or conquest must assuage ;

He grows dispirited and *low*,

He hates the fight, and shuns the foe.

Prior.

As our high vessels pass their watery way ;

Let all the naval world due homage pay ;

With hasty reverence their top-honours *lower*,

Confessing the asserted power.

Id.

When water issues out of the apertures with more
than ordinary rapidity, it bears along with it such
particles of loose matter as it met with in its passage
through the stone, and it sustains those particles till
its motion begins to remit, when by degrees it *lowers*
them, and lets them fall.

Woodward.

The heavens are not pure in his sight, and he
charges even his angels with folly ; with how *lowly*
a reverence must we bow down our souls before so
excellent a Being, and adore a Nature so much su-
perior to our own !

Rogers.

It is *low* ebb sure with his accuser, when such pec-
cadillos are put in to swell the charge.

Atterbury.

If with a true Christian *lowliness* of heart, and a
devout fervency of soul, we perform them, we shall
find that they will turn to a greater account to us,
than all the warlike preparations in which we trust.

Id.

In comparison of these divine writers, the noblest
wits of the heathen world are *low* and dull.

Felton.

Another crowd
Preferred the same request, and *lowly* bowed.

Pope.

Oh grace serene! Oh virtue heavenly fair!
Divine oblation of *lowthoughted* care!
Fresh blooming hope, gay daughter of the sky,
And faith our early immortality! *Id.*

Corruption, like a general flood,
Shall deluge all; and avarice creeping on,
Spread like a *low-borne* mist, and blot the sun. *Id.*

For from the natal hour distinctive names,
One common right the great and *lowly* claims. *Id.*

Whenever I am turned out, my lodge descends
upon a *low-spirited* creeping family. *Swift.*

The value of guineas was *lowered* from one-and-twenty shillings and sixpence to one-and-twenty shillings. *Id.*

O, had she but been of *lower* degree,
I then might have hoped she would smiled upon me!
O, how past describing had then been my bliss,
As now my distraction no words can express! *Burns.*

Without a stone to mark the spot,
And say, what Truth might well have said,
By all, save one, perchance forgot,
Ah wherefore art thou *lowly* laid? *Byron.*

LOW, *v. n.* Sax. *þlopan*; Belg. *loegen*, of old Goth. *loa*, to sound. To bellow as an ox.

Doth the wild ass bray when he has grass; or
loweth the ox over his fodder? *Job vi. 5.*

The maids of Argos, who, with frantick cries,
And imitated *lowings* filled the skies. *Roscommon.*

Fair *lō* graced *lōs* shield, but *lō* now,
With horns exalted stands, and seems to *low*. *Dryden.*

Had he been born some simple shepherd's heir,
The *lowing* herd, or fleecy sheep his care. *Prior.*

The curfew tolls the knell of parting day,
The *lowing* herds wind slowly o'er the lea,
The ploughman homeward plods his weary way,
And leaves the world to darkness and to me. *Gray's Elegy.*

LOW-BELL is a name given to the bell, by means of which they take birds in the night, in open champaign countries, and among stubble, in October. The method is to go out about nine o'clock in a still evening, when the air is mild, and the moon does not shine. The low-bell should be of a deep and hollow sound, and of such a size that a man may conveniently carry it in one hand. The person who carries it is to make it toll all the way he goes, as nearly as possible, in that manner in which the bell on the neck of a sheep tolls as it goes on and feeds. There must also be a box made like a large lantern, about a foot square, and lined with tuff, but with one side open. Two or three great lights are to be set in this, and the box is to be fixed to the person's breast, with the open side forwards, so that the light may be cast forward to a great distance, and constantly show to the person that carries it, whatever birds roost upon the ground in the large space over which it extends. Two persons must follow him who carries the box and bell, one on each side, so as not to be within the reach of the light to show themselves. Each of these is to have a hand net of about three or four feet square, fastened to a long pole; and on which ever side any bird is seen at roost, the person who is nearest is to lay

his net over it, and take it with as little noise as possible. When the net is over the bird, the person who laid it is not to be in a hurry to take the bird, but must stay till he who carries the light is got beyond it, that his motions may not be discovered. The blaze of the light, and the noise of the bell, terrify and amaze the birds in such a manner that they remain still to be taken; but the people must be very quiet. Some people go on this scheme alone. The person then fixes the light box to his breast, and carries the bell in one hand, and the net in the other; the net in this case may be somewhat smaller, and the handle shorter. When more than one are out at a time it is always proper to carry a gun; as it is no uncommon thing to see a hare when on this expedition.

LOWER (Richard), M. D., an eminent English physician in the seventeenth century, born in Cornwall, and educated at Westminster and Oxford. He practised physic under Dr. Thomas Willis, and in 1674 they discovered the medicinal waters at Astrop in Northamptonshire; which, upon their recommendations, became very much frequented. In 1666 he followed Dr. Willis to London; practised physic under him; and became fellow of the Royal Society, and of the college of physicians. In 1669 he published *Tractatus de Corde*; also *de Motu et Dolore Sanguinis*, et *Chyli in eum Transitu*. After the death of Dr. Willis, in 1765, he was esteemed the most eminent physician in London. He died in 1691.

LOWERING, among distillers, a term used to express the debasing the strength of any spirituous liquor, by mixing water with it. The standard and marketable price of these liquors is fixed, in regard to a certain strength in them, called proof; this is that strength which makes them, when shaken in a phial, or poured from on high into a glass, retain a froth for some time. In this state, spirits consist of about half pure or totally inflammable spirit, and half water; and if any foreign or home spirits are to be exposed to sale, and are found to have that proof wanting, scarcely any body will buy it, till it has been distilled again, and brought to that strength; and, if it is above that strength, the proprietor usually adds water to it, to bring it down to that standard. There is another kind of lowering among the retailers of spirituous liquors, by reducing it under the standard proof. Whoever has the art of doing this, without destroying the bubble proof, which is easily done, by means of some addition that gives a greater tenacity to the parts of the spirits, will deceive all that judge by this proof alone. In this case, the best way to judge of liquors is by the eye and tongue, and the hydrometer. See DISTILLATION.

LOWRIE (Wilson), F. R. S., an engraver of great skill and intelligence, was the son of Mr. Strickland Lowrie, a portrait painter of Whitehaven, and born there January 24th, 1762. At the age of fifteen he displayed a decided partiality for his future profession, although circumstances prevented his immediately acting upon his determination to follow it. After a youthful freak, which induced him to quit his paternal roof in company with a friend, he wandered up to Lon-

don, both supporting themselves on the road by acting occasionally as house-painters. He, however, returned to his friends, and commenced, in the neighbourhood of Worcester, an acquaintance with Mr. Ross, an engraver of some ingenuity, from whom he received his first instructions. Again visiting London, in his eighteenth year, he was fortunate enough to obtain the notice of the late alderman Boydell, by whom he was employed and introduced to Sir William Blizard. The latter finding, as he thought, a strong predilection in Lowrie for medical studies, procured him gratuitous access to the best anatomical lectures; but, after several years attendance at the hospitals, &c., Mr. Lowrie took a distaste to the profession, and returned with great ardor to engraving. He soon distinguished himself for his skill in drawing the human figure, and made a rapid progress, at the Royal Academy, in his art. Among other inventions with which he benefited, may be reckoned a ruling machine for engraving successive lines, either equidistant or in just gradation, from the greatest required distance to the nearest possible. Upon this instrument, invented in 1790, he made various improvements, and constructed one capable of drawing lines to a point, and of forming concentric circles. He introduced, in 1798, the use of diamond points for etching, and was the first person who succeeded in what is technically termed 'biting steel in' well. Mr. Lowrie, having now attained the highest rank in his peculiar line of art, was employed in 1800 on Dr. Rees's Cyclopædia, which, for nearly twenty years, occupied a large portion of his attention; Wilkins's Vitruvius, and Magna Græcia; Nicholson's Architectural Dictionary, &c. His chef-d'œuvre is considered to be an engraving from the Doric Portico at Athens, in Nicholson's Architecture. Of his engravings of machinery that of Ramsden's Sextant, given gratuitously with the instrument, is the best. Mr. Lowrie, who was elected a fellow of the Royal Society in 1812, was a favorer of the Berkeleian system, and published in the Imperial Magazine, January 1820, an ingenious letter on the Mosaic account of the deluge. He died July 1824.

LOWTH (Dr. William), a learned divine, born in London in 1661, was the son of an apothecary, and took his degree of D. D. at Oxford. His learning recommended him to Dr. Mew, bishop of Winchester, who made him his chaplain, gave him two livings in Hampshire, and conferred on him a prebend in the cathedral of Winchester. Few were more deeply versed in critical learning; there being scarcely any ancient author, Greek or Latin, profane or ecclesiastical, that he had not read, constantly accompanying his reading with critical and philosophical remarks. Of his collections in this way, he was upon all occasions very communicative: hence his notes on Clemens Alexandrinus, inserted in Potter's edition; his remarks on Josephus, communicated to Hudson for his edition; and those numerous annotations on the Ecclesiastical Historians, inserted in Reading's edition of them at Cambridge. He also assisted the author of Bibliotheca Biblica; and Dr. Chandler, late bishop of Durham, in his Defence of Christianity. His

piety, diligence, hospitality, and beneficence, rendered his life highly exemplary, and enforced his public exhortations. He married Margaret, daughter of Robert Pitt, esq., of Blandford, by whom he had two sons and three daughters. He died in 1732. He published, 1. A Vindication of the Divine Authority and Inspiration of the Old and New Testament: 2. Directions for the Profitable Reading of the Holy Scriptures; 3. Commentaries on the Prophets; and other works.

LOWTH (Robert), D. D. and F. R. S., son of the preceding, and bishop successively of St. David's, Oxford, and London, was born on the 29th of November, 1710. He studied at Winchester College, where his exercises were distinguished by their elegance; and in 1730 he went to New College, Oxford, where he continued his studies, and took the degree of M. A. June 8th, 1737. In 1741 he was elected by the university professor of Hebrew poetry, re-elected in 1743, and, whilst he held that office, he read his admirable lectures De sacra poesi Hebræorum. In 1744 bishop Hoadley appointed him rector of Ovington in Hants; in 1750 archdeacon of Winchester, and rector of East Weedhay in 1753. In 1754 the university created him D. D. by diploma. Having, in 1749, travelled with lord George and lord Frederick Cavendish, the duke being, in 1755, lord lieutenant of Ireland, Dr. Lowth went to that kingdom as his grace's first chaplain. Soon after this, he was offered the bishopric of Limerick; but, preferring a less dignified station in his own country, he exchanged it with Dr. Leslie, prebendary of Durham, and rector of Sedgfield, for these preferments. In November, 1765, he was chosen F. R. S. In June, 1766, he was, on the death of Dr. Squire, raised to the see of St. David's; and in October translated to that of Oxford. In April 1777 he was translated to the see of London, on the death of bishop Terrick; and in 1783 he declined the offer of the archbishopric of Canterbury. After having been long afflicted with the stone, he died at Fulham, November 3d, 1787. He had married, in 1752, Mary, daughter of Lawrence Jackson of Christ Church, Hants, esq., by whom he had two sons and five daughters; of whom two and his lady survived him. His literary character may be estimated from the value and the importance of his works. Besides his Prelections on the Hebrew Poetry, which have been read with applause abroad and at home, he published, in 1751, The Life of William of Wykeham, Bishop of Winchester, with a dedication to bishop Hoadley; which involved him in a dispute concerning a decision which that bishop had made respecting the wardenship of Winchester College. In 1762 was first published his Short Introduction to English Grammar, which has since gone through many editions. In 1778 he published his last great work, A Translation of Isaiah. Several occasional discourses were also published by himself, worthy of their author. Of his poetical pieces, none display greater merit than Verses on the Genealogy of Christ, and The Choice of Hercules, both written very early in his life. He wrote a spirited Imitation of an Ode of Horace, applied to the alarming situation of Britain in 1745: and

some Verses on the Death of Frederick Prince of Wales, with a few smaller poems. Learning and taste, however, did not constitute bishop Lowth's highest excellence. His amiable manners rendered him an ornament to his station, whilst they endeared him to all with whom he conversed; and his zeal for the interest of religion made him promote to places of trust and dignity such clergymen as he knew were best qualified to fill them; and, whilst virtue and learning are esteemed, the memory of Lowth will be respected.

LOXA, a large town of Spain, in Granada, situated in a romantic position on the Xenil, at the foot of the mountains which enclose the plain of Granada. Its streets rise above one another on the side of the mountain; crowned by a Moorish castle. It has some salt-works, and manufactures of copper. Inhabitants 9000. Thirty miles west of Granada, and eighteen S. S. E. of Cordova.

LOXA, a province and town of Quito, South America, abounding in bark and grain, cows and mules. Cochineal is also plentiful here. It abuts northward on Guayaquil. The town was founded in 1546, and is 237 miles south of Quito. Inhabitants 10,000.

LOXIA, in zoology, a genus of birds of the order of passerines: the distinguishing characters are these: the bill is strong, convex above and below, and very thick at the base; the nostrils are small and round; the tongue is as if cut off at the end; the toes are four, placed three before and one behind; excepting in one species, which has only two toes before and one behind. There are ninety-three species, besides many varieties. The following are among the most remarkable:

L. Abyssinica, the Abyssinian grossbeak, is about the size of the hawfinch; the bill is black; the irides are red; the top and sides of the head, throat, and breast, are black; the upper parts of the body, belly, and thighs, pale yellow, inclining to brown where the two colors divide: the scapulars are blackish; the wing-coverts brown, bordered with gray; the quills and tail brown, edged with yellow: the legs are of a reddish-gray. This bird is found in Abyssinia, and makes a curious nest of a pyramidal shape, which hangs from the ends of branches. The opening is on one side, facing the east; the cavity is separated in the middle by a partition, up which the bird rises perpendicularly about half-way, when descending, the nest is within the cavity, on one side. The brood is thus defended from snakes, squirrels, monkeys, and other mischievous animals, besides being secure from rain, which in that country sometimes lasts for six months together.

L. Bengalensis, the Bengal grossbeak, is a trifle bigger than a house-sparrow; the bill is of a flesh-color; the irides are whitish; the top of the head is of a golden yellow; the upper parts of the body are brown, with paler edges; the sides of the head and under parts rufous white; across the breast is a brown band, uniting to, and of the same color with, the upper parts of the body; the legs are of a pale yellow, the claws gray. This bird is exceedingly common in Hindostan; he is astonishingly sensible, faithful, and docile, never voluntarily deserting the place

where his young were hatched, but not averse, like most other birds, to the society of mankind, and easily taught to perch on the hand of his master. In a state of nature he generally builds his nest on the highest tree that he can find, especially on the palmyra, or on the Indian fig-tree. He makes it of grass, which he weaves like cloth, and shapes like a large bottle, suspending it firmly on the branches, but so as to rock with the wind, and placing it with its entrance downwards to secure it from birds of prey. His nest usually consists of two or three chambers; and it is the popular belief that he lights them with fire-flies, which he catches alive at night, and confines with moist clay or with cow-dung. That such flies are often found in his nest, where pieces of cow-dung are also stuck, is indubitable; but, as their light could be of little use to him, it seems probable that he only feeds on them. He may be taught with ease to fetch any small thing that his master points out to him. The young Hindoo women at Benares, and in other places, wear very thin plates of gold, called ticas, slightly fixed by way of ornament between their eye-brows; and when they pass through the streets it is not uncommon for the youthful libertines, who amuse themselves with training bayas, to give them a signal, which they understand, and send them to pluck the pieces of gold from the foreheads of their mistresses, which they bring in triumph to the lovers. The baya feeds naturally on grasshoppers and other insects; but will subsist, when tame, on pulse macerated in water.

L. cærulea, the blue grossbeak, is the size of the bullfinch: the bill is strong, brown, and the base of it surrounded with black feathers, which reach on each side as far as the eye: the plumage is in general a deep blue, except the quills and tail, which are brown, with a mixture of green, and across the wing-coverts a band of red: the legs are dusky. They inhabit South America, but are sometimes found in Carolina, where they are seen only in pairs, but disappear in winter. Their song consists only of a single note.

L. cardinalis, the cardinal grossbeak, is nearly eight inches in length. The bill is stout, and of a pale red color; the irides are hazel; the head is finely crested, the feathers rising up to a point when erect; round the bill, and on the throat, the color is black; the rest of the bird is of a fine red; the quills and tail duller than the rest, and brownish within; the legs are the color of the bill. The female differs from the male, being mostly of a reddish-brown. This species is met with in several parts of North America; and has attained the name of nightgale, from the sweetness of its song, which resembles that of the nightgale. In spring, and for the greater part of the summer, it sits on the tops of the highest trees, singing early in the morning, and piercing the ear with its loud pipe. They are fond of maize and buck-wheat; and will collect together large hoards of these, often as much as a bushel, which they artfully cover with leaves and small twigs, leaving only a small hole for entrance into the magazine. They are also fond of bees. They come in the beginning of April

into New York and the Jerseys : in autumn they depart towards Carolina. They are pretty tame, frequently hopping along the road before the traveller ; but are not gregarious, scarcely ever more than three or four being met with together.

L. chloris, the green finch, is a well known bird : the general color is a yellowish-green, palest on the rump and breast, and inclining to white on the belly ; the quills are edged with yellow, and the four outer tail-feathers are yellow from the middle to the base ; the bill is pale brown and stout ; and the legs are of a flesh color. This species is common in Britain, and flies in troops during winter. They make their nests in some low bush or hedge, composed of dry grass, and lined with hair, wool, &c., laying five or six greenish eggs, marked at the larger end with red-brown ; and the male takes his turn in sitting. These birds soon become tame ; even old ones being familiar almost as soon as caught ; they live five or six years. Like the chaffinch, they grow blind if exposed to the sun. This species is also pretty common every where on the continent, but not very frequent in Russia ; and is not at all found in Siberia, though it has been met with in Kamtschatka.

L. coccothraustes, the hawfinch, is in length about seven inches, breadth thirteen : the bill is funnel-shaped, strong, thick, and of a dull pale pink color ; the breast and whole under side are of a dirty flesh-color ; the neck ash-colored ; the back and coverts of the wings of a deep brown, those of the tail of a yellowish bay ; the greater quill-feathers are black, marked with white on their inner webs ; the tail is short, spotted with white on the inner sides ; and the legs are of a flesh-color. This species is ranked among the British birds ; but they only visit these kingdoms occasionally, for the most part in winter, and never breed here. They abound more in France, coming into Burgundy in small flocks about the beginning of April ; and soon after making their nests between the bifurcation of the branches of trees, of small dry fibres, intermixed with liverwort, and lined with finer materials. The eggs are of a roundish shape, of a bluish-green spotted with olive-brown, with a few irregular black markings interspersed. They are also common in Italy, Germany, Sweden, and the west and south parts of Russia, where the wild fruits grow. They feed on berries, kernels, &c., and, from the great strength of its bill, crack the stones of the fruit of the haws, cherries, &c., with the greatest ease.

L. curvirostra, the common cross-bill, is about the size of a lark, and is known by the singularity of its bill, both mandibles of which curve opposite ways and cross each other. The general color of the plumage in the male is of a red-lead, inclining to rose color, and more or less mixed with brown ; the wings and tail are brown ; the legs black. The female is of a green color, more or less mixed with brown in those parts where the male is red. This species inhabits Sweden, Germany, Poland, Switzerland, Russia, and Siberia, where it breeds ; but migrates sometimes in vast flocks into Britain and other countries ; for, though in some years

few are met with, yet in others they have visited us by thousands, fixing on such spots as are planted with pines, for the sake of the seeds, which are their natural food. They hold the cone in one claw like the parrot. They also visit North America and Greenland ; and make their nests in the highest parts of fir-trees, fastening them to the branches with the resinous matter which exudes from the trees.

L. enucleator, the pine grossbeak, is about nine inches long. The bill is strong, dusky, and forked at the end ; the head, back, neck, and breast, are of a rich crimson ; the bottoms of the feathers ash-color ; the quill-feathers and tail dusky, their exterior edges of a dirty white ; the legs are black. This species frequents the most northern parts of this kingdom, being only met with in Scotland, especially the Highlands, where they breed, and inhabit the pine-forests, feeding on the seeds, like the cross-bill. They also abound in the pine-forests of Siberia, Lapland, and the north of Russia ; and are common about St. Petersburg in autumn, where they are caught in great plenty for the table. They return north in spring. They are likewise common in the north parts of America, appearing at Hudson's Bay in May, and feeding on the buds of the willow.

L. orix, the grenadier grossbeak, is about the size of a house sparrow. The forehead, sides of the head, and chin, the breast and belly, are black ; the wings are brown, with pale edges ; and the rest of the body is of a beautiful red color ; the legs are pale. These birds inhabit St. Helena, and the Cape of Good Hope ; frequenting watery places that abound with reeds, among which they are supposed to make their nest. These birds, among the green reeds, from the brightness of their colors, appear like so many scarlet lilies.

L. pensilis, the pensile grossbeak, the toddy bird of Fryer, is about the size of the house sparrow : the bill is black, the feet are yellow ; the head, throat, and fore part of the neck, the same ; from the nostrils springs a dull green stripe, which passes through the eye and beyond it, where it is broader ; the hind part of the head and neck, the back, rump, and wing coverts, are of the same color ; the quills are black, edged with green ; the belly is deep gray, and the tail and legs are black. This species is found at Madagascar, and fabricates a nest of a curious construction, composed of straw and reeds interwoven in shape of a bag, the opening beneath. It is fastened above to a twig of some tree ; mostly to those growing on the borders of streams. On one side of this, within, is the true nest. The bird does not form a new nest every year, but fastens a new one to the end of the last ; and often as many as five in number, one hanging from another. These build in society like rooks, 500 or 600 being often seen on one tree.

L. Philippina, the Philippine grossbeak, is about the size of a sparrow : the top of the head, the hind part of the neck and back, and the scapulars, are yellow, the middle of the feathers brown ; the lower part of the back is brown, with whitish margins ; the fore part of the neck

and breast are yellow; and thence to the vent yellowish white; the wing coverts brown, edged with white; the quills are brown, with pale rufous, or whitish edges; and the tail the same; the legs are yellowish. These birds inhabit the Philippine Islands, and are noted for making a most curious nest, in form of a long cylinder, swelling out into a globose form in the middle. This is composed of the fine fibres of leaves, &c., and fastened by the upper part to the extreme branch of a tree. The entrance is from beneath; and after ascending the cylinder, as far as the globular cavity, the true nest is placed on one side of it; where this little architect lays her eggs, and hatches her brood in perfect security. A variety of this species, the *baglafechat*, an inhabitant of Abyssinia, makes a very curious nest like the former, but a little different in shape, which is said to have somewhat of a spiral form, not unlike that of a nautilus. It suspends it, like the other, on the extreme twig of some tree, chiefly one that hangs over some still water; and always turns the opening towards that quarter whence least rain may be expected.

L. pyrrhula, the bullfinch, is well known. The head, wings, and tail, are black; the breast and belly red; the upper tail coverts and vent white; and the breast ash-color. The female differs in having the under parts of a reddish brown. This species is common in most parts of the continent, and throughout Russia and Siberia, where it is caught for the table. They are pretty common in England, and build in bushes, five or six feet from the ground. The nest is composed chiefly of moss; and the eggs, which are five or six in number, are dirty bluish white, marked at the large end with dark spots. The time of breeding is about the end of May, or beginning of June. In summer they frequent woods and retired places. In winter they approach gardens and orchards, and make havoc among the buds of trees. The bullfinch, in its wild state, has only a plain note, but when tamed it becomes remarkably docile, and may be taught any tune after a pipe, or to whistle any notes in the justest manner; it seldom forgets what it has learned; and will become so tame as to come at call, perch on its master's shoulders, and, at command, go through a difficult musical lesson. They may be also taught to speak, and some thus instructed are annually brought to London from Germany.

L. socia, the sociable grossbeak, is about the size of a bullfinch: the general color of the body above is rufous brown, the under parts yellowish; the beak and muzzle are black; the legs brown, and the tail is short. It inhabits the interior country at the Cape of Good Hope. These birds live together in large societies, and their mode of nidification is extremely uncommon. They build in a species of mimosa, which grows to an uncommon size, and which they seem to select for that purpose, as well on account of its ample head, and the great strength of its branches, calculated to admit and to support the extensive buildings which they have to erect, as for the tallness and smoothness of its trunk, which their great enemies, the serpent

tribe, are unable to climb. The method in which the nests themselves are fabricated is highly curious. In one described by Mr. Paterson there could be no less a number, he says, than from 800 to 1000 residing under the same roof. He calls it a roof, because it perfectly resembles that of a thatched house; and the ridge forms an angle so acute and so smooth, projecting over the entrance of the nest below, that it is impossible for any reptile to approach them. The industry of these birds 'seems almost equal,' says our author, 'to that of the bee; throughout the day they appear to be busily employed in carrying a fine species of grass, which is the principal material they employ for the purpose of erecting this extraordinary work, as well as for additions and repairs. Many trees I have seen borne down with the weight, and others I have observed with their boughs completely covered over. One of the deserted nests I had the curiosity to break down, so as to inform myself of the internal structure of it, and found it equally ingenious with that of the external. There are many entrances, each of which forms a regular street, with nests on both sides, at about two inches distance from each other. The grass with which they build is called the boshman's grass; and I believe the seed of it to be their principal food; though, on examining their nests, I found the wings and legs of different insects.'

L. tridactyla, the three-toed grossbeak, the *guisso balito* of Buffon, has only three toes, two before and one behind. The bill is toothed on the edges: the head, throat, and forepart of the neck, are of a beautiful red, which is prolonged in a narrow band quite to the vent; the upper part of the neck, back, and tail, are black; the wing coverts brown edged with white; quills brown, with greenish edges; and legs a dull red: the wings reach half way on the tail. This species inhabits Abyssinia; where it frequents woods, and is a solitary species. It feeds on kernels of seeds, which it breaks with ease with its bill.

LOXODROM'ICK, *n. s.* Gr. *λοξος*, oblique and *δρόμος*, a course. Oblique sailing.

Loxodromick is the art of oblique sailing by the rhomb, which always makes an equal angle with every meridian; that is, when you sail neither directly under the equator, nor under one and the same meridian, but across them: hence the table of rhombs, or the transverse table of miles, with the table of longitudes and latitudes, by which the sailor may practically find his course, distance, latitude, or longitude, is called *loxodromick*. Harris.

LOYAL, *adj.* Fr. *loyal*, *loi* (law); Ital. **LOYALIST**, *n. s.* } *leale* (le); Span. *leal* (le).
LOY'ALLY, *adv.* } Strictly, attached or ob-
LOY'ALTY, *n. s.* } dient to the laws of one's country, and hence to the sovereign; faithful to vows or engagements of any kind. A loyalist is an adherent to the king or sovereign power. Loyalty (Fr. *loiauté*), fidelity to prince or country; or any object of vows or attachment.

The regard of duty in that most loyal nation overcame all other difficulties. Knolles.

Of *Gloster's* treachery,
And of the *loyal* service of his son,
When I informed him, then he called me sot.

Shakspeare.

Though *loyalty*, well held, to fools does make
Our faith more folly; yet he that can endure
To follow with allegiance a fallen lord,
Does conquer him that did his master conquer. *Id.*

What though you be *loyal* to earthly kings and
their crowns and kingdoms, yet if you be traitors and
rebels against the king of his church, Jesus Christ,
and the sceptre of his kingdom; not suffering him
by his laws and officers to reign over you, shall
your *loyalty* towards men excuse your treasons
against the Lord.

Bp. Hall.

The cedar, by the instigation of the *loyalists*, fell
out with the homebians. *Houel's Local Forest.*

He had never any veneration for the court, but
only such *loyalty* to the king as the law required.

Clarendon.

Hail wedded love! by thee
Founded in reason *loyal*, just, and pure. *Milton.*
Abdiel faithful found

Unshaken, unseduced, unterrified,
His *loyalty* he kept. *Id.*

For *loyalty* is still the same,
Whether it win or lose the game;
True as the dial to the sun,

Although it be not shone upon. *Hudibras.*

There Laodamia with Evadne moves,
Unhappy both, but *loyal* in their loves. *Dryden.*

Loyal subjects often seize their prince,
Yet mean his sacred person not the least offence.

Id.

The circling year I wait, with ampler stores,
And fitter pomp, to hail my native shores;
Then by my realms due homage would be paid,
For wealthy kings are *loyalty* obeyed.

Pope's Odyssey.

The most inviolable attachment to the laws of our
country is every where acknowledged a capital vir-
tue; and, where the people are not so happy as to
have any legislature but a single person, the strictest
loyalty is, in that case, the truest patriotism.

Hume.

We too are friends to *loyalty*. We love
The being, who loves the law respects his bounds,
And reigns content within them. *Cooper.*

LOYOLA (Ignatius), the founder of the order
of the Jesuits, was born at the castle of Loyola,
in Guipuscoa, in 1491; and became first page to
Ferdinand V., king of Spain, and then an officer
in his army. In this last capacity he signa-
lised himself by his valor; and had his right leg
broken by a cannon ball, at the siege of Pam-
peluna, in 1521. While confined by his wound,
a Life of the Saints was put into his hands,
which determined him to forsake the military
for the ecclesiastical profession. His first de-
vout exercise was to dedicate himself to the
Blessed Virgin as her knight. He then practi-
sed the most severe mortifications for above a
year; after which he went a pilgrimage to the
Holy Land; and, on his return to Europe, he
continued his theological studies in the univer-
sities of Spain, though he was then thirty-three
years of age. In 1526, upon commencing
preacher, he was imprisoned at Alcala and Sala-
manca, and impeached before the inquisition.
After this he went to Paris, and laid the founda-
tion of his new order; the institutes of which he
presented to pope Paul III., who made many
objections to them, but at last confirmed the in-

stitution in 1540. He died in Rome, July 31st
1556, aged sixty-six; and left his disciples two
celebrated works; 1. *Spiritual Exercises*; 2.
Constitutions, or Rules of the Order. But, though
these avowed institutes contain many privileges
obnoxious to the welfare of society, the most ob-
jectionable are contained in the private rules
entitled *Monita Secreta*, which were not disco-
vered till the close of the seventeenth century;
and most writers attribute these, and even the
Constitutions, to Laynez, the second general of
the order.

LOZENGE, *n. s.* Fr. *losenge*, Gr. *λοζος*,
oblique. A rhomb; a preserved fruit, or medici-
nal cake, of this form.

Not icladde in silke was he,
But all in flowris and flowrettes,
I painted all with amorettes,
And with *losings* and scochons,
With birdis, liberdes, and lions,
And othir bestis wrought ful well.

Chaucer. Romaunt of the Rose.

The best builders resolve upon rectangular squares,
as a mean between too few and too many angles;
and, through the equal inclination of the sides, they
are stronger than the rhomb or *losenge*.

Wotton's Architecture.

They are of two sorts, square and *losenge*:
the first is used in cutting very broad strokes, the other
for fainter and more delicate lines.

Intson's Elements.

LOZENGE, in heraldry. See HERALDRY.
Though all heralds agree that ladies are to place
their arms on lozenges, yet they differ with re-
spect to the causes that gave rise to it. Plutarch
says, in the life of Theseus, that in Megara, an
ancient town of Greece, the tomb-stones, under
which the bodies of the Amazons lay, were of that
form. S. Petra Sancta says, this shield repre-
sents a cushion, on which women used to sit and
spin. Sir J. Ferne thinks it is formed from the
shield called Tesra, which the Romans finding
unsit for war, allowed women to place their en-
signs upon, with one of its angles always upper-
most.

LOZENGES, among jewellers, are common to
brilliant and rose diamonds. In brilliants they
are formed by the meeting of the skill and star
facets on the bezil; in the latter by the meeting
of the facets in the horizontal ribs of the crown.
See FACET.

LOZERE, a department of France, is formed
of the ancient district of the Gevaudan and part
of the Cevennes dependent on the former pro-
vince of Languedoc, and takes its name from a
small chain of mountains, being part of those
called the Cevennes mountains. The chief place
is Mende; it consists of three arrondissements
or subprefectures, Mende containing 43,821 in-
habitants; Florac 39,453; Marvejols 50,660;
making a total population of 133,934 souls, on
an area of 2421 square miles. It is subdivided
into twenty-four cantons, and 191 communes,
yielding a territorial revenue of 5,904,000 francs,
is in the ninth military division, with two elec-
toral arrondissements, which send two members
to the chamber of deputies. It has a royal court
at Nismes, and a bishopric at Mende. This de-
partment is bounded on the north by those of
Cantal and the Upper Loire; on the east by

those of Ardeche and the Gard ; on the south by the Gard, and on the west by that of the Aveyron. It is intersected by mountains, on which are many lakes abounding in fish, and by valleys and plains of moderate extent and not very fertile. It is divided by nature into three parts, known by their respective names of Montagnes, Causses, and Cevennes ; the first of which produces rye, a small quantity of barley and oats and forage ; the second, which is the most fertile, yields wheat, small grain, forage, and fruits ; the third produces a little rye, chestnuts, and a great quantity of potatoes. The Cevennes mountains extend over part of this department, from one of the peaks of which, the mountain of Lozère, it derives its name ; they are covered with snow during a part of the year. Among the plants which grow spontaneously in these mountains, are many that are useful in pharmacy. Great flocks of sheep are reared here, and a great number of mules ; during the summer also they receive flocks from Lower Languedoc. In some parts the mulberry tree is cultivated with tolerable success. The temperature of the atmosphere is very variable ; at some periods, and at certain degrees of altitude, two or three different temperatures are experienced in the same day. In the north the winter lasts for six months, and in some years even nine ; but towards the south it scarcely continues four months. The height of the sun and the numerous waters render this country cold and damp, and this is the common temperature of the department ; the winters are usually severe, the spring seasons rainy, the summers often stormy, and the autumns fine only towards the end. This mountainous country is cultivated with oxen, and does not yield a sufficient supply for its inhabitants. There are 21,681 hectares of forests and very few vineyards ; the mean produce of every hectare of arable land is ten francs ninety-four centimes.

Here are also mines of iron, lead, antimony, silver, and copper, and quarries of marble, granite, porphyry, and plaster. At Bagnols there are mineral waters. The manufacture of serges, and cotton spinning, is carried on successfully ; mines of copper and lead are worked, and various foundries. A number of workmen annually emigrate to the south, to attend the cultivation of the silk-worm, and at the same time to labor at the hay making and the harvest. The people trade in wine, chestnuts, oil, coarse cloths, serges, and cotton yarn.

The principal rivers are the Tarn, the Lot, the Allier, the Gardon, the Chassezal, the Truyere, the Reze, the Tarnon, the Mimente, the Jaute and the Cologne. It is crossed by none of the great royal roads ; but fourteen different cross roads serve to promote the communication ; goods are chiefly conveyed on mules.

LOZERE, *THE*, a high mountain in the Cevennes, situated at the eastern extremity of the department, to which it gives its name. It is about 1473 metres above the level of the sea, and a plat of granite on the top, in shape bearing resemblance to the back of an ass, about ten or twelve miles long, covered with fine pastures and thick forests.

LU, *n. s.* A game at cards. See Loo.

LUB'BARD, *n. s.* } Perhaps from *LoB*,
LUB'BER, } which see. There
LUB'BERLY, *adj. & adv.* } are also Belg. *lobben*,
emasculated, and *lugard*, a lout, probable deri-
vations. A sturdy, lazy fellow. Lubberly is
awkward ; clownish.

For tempests and showers deceiveth a many,
And lingering lubbers loose many a penie. *Tusser.*

They clap the lubber Ajax on the shoulder,
s if his feet were on brave Hector's breast,
And great Troy shrinking.

Shakspeare. Troilus and Cressida.

A notable lubber thou reportest him to be.

Shakspeare.

I came to Eaton to marry Mrs. Anne Page ; and
she's a great lubberly boy. *Id.*

These chase the smaller shoals of fish from the
main sea into the havens, leaping up and down puff-
ing like a fat lubber out of breath. *Carew.*

Tell how the drudging goblin sweat ;

His shadowy flail hath thrashed the corn,

That ten day labourers could not end ;

Then lies him down the lubber fend. *Milton.*

Merry Andrew on the low rope copies lubberly the
same tricks which his master is so dexterously per-
forming on the high. *Dryden.*

Venetians do not more uncouthly ride,
Than did your lubber state mankind bestride.

Id.

How can you name that superannuated lubber ?

Congreve.

Yet their wine and their victuals those curmudgeon

lubbards

Lock up from my sight in cellars and cupboards.

Swift.

LUBEC, or LUBECK, a city and port of Ger-
many, in Lower Saxony. It is seated at the
conflux of the Trave with the Steckenitz, the
Elbe, the Wackentiz, &c., twelve miles from the
Baltic, where it has a fine harbour. By the
Steckenitz and the Elbe it communicates with
the German Ocean. The city lies on the side of
a hill, with the Trave, increased by the Stecke-
nitz on the one side, and the Wackentiz on the
other ; and is strongly fortified with bastions,
walls, and ramparts ; the last of which are planted
with trees, and for man agreeable walk. Lubec,
being formerly the chief of the Hanse Towns was
very powerful, but a great part of its trade is
now transferred to Hamburg ; however, it still
employs 100 ships, and has a fair share of the
Baltic trade. It is about two miles long, and
more than one broad. The houses are of stone.
Several of the streets have on each side rows of
lime trees, with canals in the middle. The
chief public structures are the cathedral, the
church of St. Mary's, several Lutheran churches,
a nunnery with an abbess, and prioress ; a poor's
house, an alms-house, orphan house, a hospital
dedicated to the Holy Ghost, a house in which
poor travellers are entertained three days, and
then sent forward with a pass, or provided with
medicine if ill ; a Calvinistic church, and Ca-
tholic Chapel. The deputies of the Hanse
Towns used to meet in the town house of Lu-
bec. Inhabitants 55,000. It is forty miles
north-east of Hamburg. In 1802 Lubec had
seventy to eighty merchant vessels of burthen,
and in the same year there entered 1368 vessels,
and cleared out 1234. It has manufactories of
cordage and sail-cloth, sugar refineries and to-

bacco manufactories, and builds merchant vessels. Travemunde is a village of fishermen and pilots, on the north bank of the river; it has a fortress mounting forty cannons. Its port, where vessels above 200 tons lighten to ascend to Lubec, can hold sixty sail. A packet sails between this place and Petersburg.

LUBIENITSKI (Stanislaus), a Polish gentleman, born at Cracow in 1623, and educated by his father. He became a celebrated Socinian minister; and endeavoured to obtain toleration from the German princes for his brethren. His labors, however, were ineffectual; being himself persecuted by the Lutheran ministers and banished from place to place, until at length, in 1675, he was poisoned with his two daughters, his wife narrowly escaping. He wrote, 1. A History of the Reformation in Poland; 2. A History of Comets, from the Flood to 1665: and other works in Latin.

LUBIN (Augustin), according to Dr. Watkins, or Nicholas Lubin according to others, geographer to Louis XIV., and an Augustine monk, was born in 1624. He wrote a description of Lapland; Sacred Geography; and several other works. He died in 1695, aged seventy-one.

LUBIN (Elihard), a Protestant divine, born at Westersted in Germany, and educated at Leipsic. He became professor of poetry in the university of Rostock, in 1595: and in 1605 professor of divinity. He wrote notes on Anacreon, Juvenal, Persius, &c., and several other works; but his most celebrated production is a treatise on the nature and origin of evil, entitled *Phosphorus de Causâ primâ et Naturâ Mali*, printed at Rostock in 1596; in which we have a curious hypothesis to account for the origin of moral evil. He supposed two co-eternal principles; not matter and vacuum, as Epicurus did: but God, and Nihilum or Nothing.

LUBLIN, a considerable town of Poland, capital of the palatinate of the same name, with a citadel, a bishop's see, a university, a Jewish synagogue, and judicial courts. It has three fairs, frequented by merchants from all nations. It is seated on the Bystrzna. Long. 22° 31' E., lat. 51° 26' N.

LUBRICATE, <i>v. a.</i>	} Lat. <i>lubricus</i> . To make smooth, slippery, or of easy movement. Lubricity is smoothness; aptness to move or glide easily; slipperiness; uncertainty; wantonness. Lubric and lubricous are, smooth; slippery; loose; unsteady; wanton. Lubrification and lubrification, the act of making smooth or lubricous.
LUBRICITY, <i>n. s.</i>	
LUBRIC, <i>adj.</i>	
LUBRICOUS,	
LUBRIFICATION, <i>n. s.</i>	

The cause is *lubrification* and relaxation, as in medicines emollient; such as milk, honey, and mallows.

I will deduce him from his cradle through the deep and *lubrick* waves of state, till he is swallowed in the gulph of fatality. Wotton.

A throng
Of short thick sobes, whose thundering volleys float
And roll themselves over her *lubrick* throat
In panting murmurs. Crashaw.

He that enjoyed crowns, and knew their worth,
excepted them not out of the charge of universal

vanity; and yet the politician is not discouraged at the inconstancy of human affairs, and the *lubricity* of his subject. Glanville's Apology.

The judgment being the leading power, if it be stored with *lubricous* opinions instead of clearly conceived truths, and peremptorily resolved in them, the practice will be as irregular as the conceptions. Id. Scepia.

The manifold impossibilities and *lubricities* of matter cannot have the same conveniences in any modification. More.

From the lechery of these fauns, he thinks that satyr is derived from them, as if wantonness and *lubricity* were essential to that poem which ought in all to be avoided. Dryden.

Why were we hurried down

This *lubrick* and adulterate age;

Nay, added fat pollutions of our own,
T' increase the steaming ordures of the stage? Id.

A state of tranquillity is never to be attained, but by keeping perpetually in our thoughts the certainty of death and the *lubricity* of fortune. L'Etrange.

Both the ingredients are of a *lubricating* nature; the mucilage adds to the *lubricity* of the oil, and the oil preserves the mucilage from inspissation. Ray on Creation.

A twofold liquor is prepared for the inunction and *lubrification* of the heads of the bones; an oily one, furnished by the marrow; a mucilaginous, supplied by certain glandules seated in the articulations. Id.

The parts of water being voluble and *lubricous*, as well as fine, it easily insinuates itself into the tubes of vegetables, and by that means introduces into them the matter it bears along with it. Woodward's Natural History.

There are aliments which, besides this *lubricating* quality, stimulate in a small degree. Arbutnot on Aliments.

The patient is relieved by the mucilaginous and the saponaceous remedies, some of which *lubricate*, and others both *lubricate* and stimulate. Sharp.

To trace in Nature's most minute design
The signature and stamp of power divine,
Contrivance intricate, expressed with ease,
Where unassisted sight no beauty sees;
The shapely limb and *lubricated* joint,
Within the small dimensions of a point,
Muscle and nerve miraculously spun;
His mighty work, who speaks and it is done. Couvpr.

LUCANIA, a country of Italy, and a part of Magna Græcia; bounded on the north by the Silarus, by which it is separated from the Picentini, and by the river Bradanus, by which it is parted from the Apuli Peucetii; on the south by the Laus, which separated it from the Bruttii; on the east by the Sinus Tarentinus; and on the west by the Tuscan Sea.

LUCANUS (Marcus Annæus), a Latin poet, born at Corduba in Spain, about A. D. 39. He was the son of Annæus Mela, the youngest brother of Seneca; and was conveyed to Rome at the age of eight months. At Rome he was educated under the Stoic Cornutus, so warmly celebrated by his disciple Persius the satirist, who was the intimate friend of Lucan. In the close of his education, Lucan is said to have passed some time at Athens. On his return to Rome he rose to the office of questor, before he had attained the legal age. He was afterwards enrolled among the augurs; and married a lady of

noble birth. Lucan had for some time been admitted to familiarity with Nero, when the emperor chose to contend with him for poetical honors by the public recital of a poem he had composed on Niobe. Lucan had the hardness to repeat a poem on Orpheus, in competition with that of Nero; and the judges of the contest were just and bold enough to decide against the emperor. Hence Nero became the persecutor of his successful rival, and prohibited him to produce any poetry in public. The well known conspiracy of Piso against the tyrant soon followed; and Tacitus concludes that Lucan engaged in the enterprise from the poetical injuries he had received. His firmness and intrepidity are very forcibly displayed in the picture of his death which Tacitus has given us. He was condemned to have his veins opened, as his uncle Seneca had before him; and, 'while his blood issued in streams, perceiving his feet and hands to grow cold and stiffen, and life to retire by little and little from the extremities, while his heart was still beating with vital warmth, and his faculties nowise impaired, he recollected some lines of his own, which described a wounded soldier expiring in a manner that resembled this. These lines he rehearsed; and they were the last words he ever uttered.' The critics differ concerning the verses of the *Pharsalia* which the author repeated. Some think the verses were v. 810 to 814, lib. ix., but Lipsius contends, that the passage occurs in lib. iii. v. 635—638; thus translated by Mr. Rowe:

No single wound the gaping rupture seems,
Where trickling crimson swells in slender streams;
But, from an opening horrible and wide,
A thousand vessels pour the bursting tide:
At once the winding channel's course was broke;
Where wandering life her mazy journey took;
At once the currents all forgot their way,
And lost their purple in the azure sea.

Such was the death of Lucan, before he had completed his twenty-seventh year. His wife, Polla Argentaria, is said to have transcribed and corrected the first three books of his *Pharsalia* after his death. Quintilian disputes the title of Lucan to be classed among the poets; and Scalliger says, that he seems rather to bark than to sing. But the most elevated poetic spirits have been his warmest admirers; in France he was idolised by Corneille, and in England translated by Rowe. The severest censures on Lucan have proceeded from those who have unfairly compared his language to that of Virgil; but how unjust is such a comparison! How differently should we think of Virgil as a poet, if we possessed only the verses which he wrote at that period of life when Lucan composed his *Pharsalia*! In the disposition of his subject, in the propriety and elegance of diction; he is undoubtedly far inferior to Virgil; but, if we attend to the bold originality of his design, and to the vigor of his sentiments; if we consider the *Pharsalia* as the rapid and uncorrected sketch of a young poet, executed in an age when the spirit of his countrymen was broken, and their taste in literature corrupted; it may be justly esteemed one of the most noble and most wonderful productions of the human mind. Lucan wrote

several poems, but none remain besides his *Pharsalia*.

LUCANUS, the stag-beetle, in zoology, a genus of insects of the order coleoptera. The antennæ end in a club or knob, which is compressed or flattened on one side, and divided into short laminæ resembling the teeth of a comb; the jaws are protracted or advanced before the head, and are dentated. See ENTOMOLOGY.

L. cervus is the largest as well as the most singular species. It has two large moveable maxillæ, resembling the horns of a stag, which project from its head, and have acquired it the appellation of stag-beetle. Those maxillæ, broad and flat, equal to one-third of its length, have in the middle, towards their inner part, a small branch, and at their extremity are forked. They have also several small teeth throughout their length. The head that bears these maxillæ is irregular, very broad, and short. The thorax is something narrower than the head and body, and margined round. The elytra are very plain, without either streaks or lines. The whole animal is of a deep brown color. It is commonly found upon the oak, but is scarce in the neighbourhood of London; and, though the largest of coleopterous insects to be met with in this part of the world, it is much smaller than those of the same species that are found in woody countries. It is strong and vigorous, and its horns, with which it pinches severely, are carefully to be avoided. The jaws are sometimes as red as coral, which gives this insect a very beautiful appearance; the female is distinguished by the shortness of the jaws, which are not half so long as those of the male. The females deposit their eggs in trunks of decayed trees, such as the oak and the ash. The larvæ lodge under the bark, and in the hollow of old trees, which they eat into and reduce into fine powder, and there transform themselves into chrysalids. They are common in Kent and Sussex, and are sometimes met with in other parts of England. The protracted jaws are particularly useful to these animals, in stripping off the bark from trees, and affixing themselves thereby to the tree, while they suck with their trunk the juice that oozes from it.

LUCARIA, from Lat. *lucus*, a grove, a feast celebrated at Rome, on the 18th of July, in memory of the flight of the Romans into a wood, where they found an asylum from the Gauls. This wood was situated between the Tiber and the Via Salaria. On this festival, Plutarch informs us, it was customary to pay the actors with the money arising from the felling of wood. This money was called *lucar*.

LUCAS (Richard), D. D., a learned English divine, born in 1648, and educated at Oxford; after which he took orders, and was for some time master of the free school at Abergavenny. Being esteemed an excellent preacher, he became vicar of St. Stephen's Coleman Street, and lecturer of St. Olave's in Southwark. In 1696 he was installed prebendary of Westminster. His sight began to fail in his youth, and he totally lost it in his middle age. He was greatly esteemed for his piety and learning; and published several works, particularly; 1. Practical

Christianity; 2. An Enquiry after Happiness; 3. Several Sermons; 4. A Latin translation of the whole Duty of Man. He died in 1715.

LUCAS JACOBS, or LUCAS VAN LEYDEN, an eminent artist, called also Hugense, was born at Leyden in 1494. He received his first instructions in painting from his father Hugues Jacobs: but completed his studies under Cornelius Engelbrecht. A few years before his death, it is said that during a journey through Zealand and Brabant a painter of Flushing, envious of his great abilities, gave him poison at an entertainment, which, though slow, was fatal in its effects, and put an end to his life, after six years languishing under its cruel influence. Others, however, attribute his death to his incessant industry. The superiority of his genius manifested itself very early; for his works, even when but nine years of age, were so excellent as to excite the admiration of all contemporary artists; and, when he was about fifteen, he painted a St. Hubert which gained him great applause. His tone of coloring, Mr. Pilkington observes, is good; his attitudes are well chosen; his figures have a considerable expression in their faces; and his pictures are very highly finished. He endeavoured to proportion the strength of his coloring to the different degrees of distance in which his objects were placed: for, in that early time, the true principles of perspective were but little known. In the town-hall at Leyden his finest picture, the Last Judgment, is preserved with great care; the magistrates having refused very large sums for it. Lucas painted not only in oil, but also in distemper and upon glass. Nor was he less eminent for his engraving. The strokes are as delicate upon the objects in the front, as upon those in the distances; and this want of variety, joined with the feebleness of the masses of shadow, gives his engravings, with all their neatness, an unfinished appearance. He was attentive to the minutie of his art. He gave great expression to the heads of his figures; but in his works the same heads are too often repeated. The hands and feet are rather mannered than correct; and, when he attempted to draw the naked figure, he succeeded but indifferently. He made the folds of his draperies long and flowing; but his female figures are too often excessively loaded with girdles, bandages, and other ornamental trappings. He engraved on wood, as well as on copper; but his works on the former are not numerous. They are, however, very spirited; though not equal, upon the whole, to those of his friend Albert. Lucas's prints are pretty numerous, but seldom met with complete. The following are among the principal: 1. Mahomet sleeping, with a priest murdered by his side, and another figure stealing his sword; a middling-sized upright plate, 1508. 2. An ecce homo, a large plate, lengthwise, 1510. 3. The crucifixion on Mount Calvary, 1510. 4. The wise men's offering, on Mount Calvary, 1513. 5. Return of the prodigal son, middling-sized, lengthwise, 1518. 6. The dance of Magdalen, large, lengthwise, 1519. 7. His own portrait, small, upright, 1525. 8. David playing before Saul, a middling-sized, upright, very fine print. 9. A print called Ulespiegle, which is the scarcest

of all his works. It was in the collection of the king of France; and said by Marolles to be unique; but Mariette had also an impression of it. It represents a travelling bag-piper with his family, consisting of his wife, seven children, a little dog, &c., in a singular group. This rare print is dated 1520, and has been sold for sixteen louis d'ors. It is nearly seven inches and a half high by four and three-quarters broad; and has been twice copied.

LUCCA, DUCHY OF, is a small principality created a duchy by the congress of Vienna in 1815, and given in full sovereignty to her majesty the Infanta Maria Louisa of Spain, and her descendants in the direct male line. It is encompassed by Tuscany, Modena, and the Mediterranean, and contains about 430 square miles. Much of it is mountainous, and its scenery is picturesque and beautiful, while the industry of the inhabitants has covered numerous hills to their very summits with vines, olives, chestnuts, and mulberry trees. The atmosphere has all the mildness and serenity of Italy, and the delightful plain on which the capital stands, and the valleys in other parts of the duchy, are composed of black alluvial soil, abounding with rich pasturage. Some grain is produced, but wine, oil, and silk, are the chief products. Inhabitants 124,000.

Lucca, the capital, is situated near the southern confines, on the river Serchio. It is about three miles in circumference. Its ramparts are planted with trees. Several of the churches are built of Carrara marble. The cathedral and St. Michael's are the most elegant. The princess's palace is a large structure surrounded with trees, and many of the nobility have elegant mansions in the vicinity. Here are a university, an academy of arts and sciences, and a celebrated establishment for the education of females, of noble birth. There are likewise manufactures of cloth and silk, but the principal trade is in oil. The baths of Lucca are on the banks of the Serchio near the town and much frequented. The religion is Catholic, the army about 800, and the yearly income of the duchy nearly £65,000. The inhabitants, who are a moral and industrious race, amount to about 18,000.

LUCE, *n. s.* Lat. *lupus*. A pike full grown

Ful many a fat partrich had he in mewe,

And many a breme and many a luce in stew.

Chaucer. Cant. Tales.

They give the dozen white luges in their coast.

Shakspeare.

LUCE, in ichthyology. See ESOX.

LUCENA, a large inland town of Cordova, in the south of Spain. It contains three infirmaries a foundling hospital, and eleven poor houses; and it has manufactures of linen, cloth, and soap, besides the adjacent salt works of Jarales. Population 12,000: thirty-two miles S. S. E. of Cordova. Long. 4° 29' W., lat. 37° 32' N. There are two other small towns of this name in Andalusia, and Valencia.

LUCENT, *adj.*

Luc'ID, *adj.*

LUCIDITY, *n. s.*

LUCIFEROUS, *adj.*

Lucif'ER, *adj.*

Lat. *lucens*, *lucidus*; Fr.

lucide. Bright; shining;

resplendent; clear; pel-

lucif'EROUS, *adj.* applied metapho-

rically to clearness

brightness of intellect as opposed to insanity: luciferous is giving light: lucific, making or creating light.

The long dissensions of the two houses, which, although they had had *lucid* intervals and happy pauses, yet they did ever hang over the kingdom, ready to break forth. *Bacon.*

I meant the day-star should not brighter rise,
Nor lend like influence from his *luculent* seat.

Ben Jonson.

A spot like which perhaps
Astronomer in the sun's *luculent* orb,
Through his glazed optick tube yet never saw.

Milton.

Over his *lucid* arms
A military vest of purple flowed;
Livelier than Malibœan. *Id.*

On the fertile banks
Of Abana and Pharpar, *lucid* streams. *Id.*

The experiment is not ignoble, and *luciferous* enough, as shewing a new way to produce a volatile salt. *Boyle.*

Some beams of wit on other souls may fall,
Strike through and make a *lucid* interval;
But Shadwell's genuine night admits no ray,
His rising fogs prevail upon the day. *Dryden.*
It contracts it, preserving the eye from being injured by too vehement and *lucid* an object, and again dilates it for the apprehending objects more remote in a fainter light. *Ray.*

When made to converge, and so mixed together;
though their *lucifick* motion be continued, yet by interfering, that equal motion, which is the colorfick, is interrupted. *Grew.*

I believed him in a *lucid* interval, and desired he would please to let me see his book. *Tatler.*

A few sensual and voluptuous persons may, for a season, eclipse this native light of the soul; but can never so wholly smother and extinguish it, but that, at some *lucid* intervals, it will recover itself again, and shine forth to the conviction of their conscience. *Bentley.*

The pearly shell its *lucid* globe unfold,
And Phœbus warm the ripening ore to gold.

Pope.

On the transparent side of a globe, half silver and half of a transparent metal, we saw certain strange figures circularly drawn, and thought we could touch them, till we found our fingers stopped by that *lucid* substance. *Gulliver's Travels.*

Beneath the hedge or near the stream,

A worm is known to stray,

That shows by night a *lucid* beam,

Which disappears by day. *Couper.*

Nymphs! on that day ye shed from *lucid* eyes,
Celestial tears, and breathed ethereal sighs!
When Richman reared, by fearless haste betrayed,
The wiry rod in Nieva's fatal shade. *Darwin.*

The sun-born blood suffused her neck, and threw
O'er her clear nut-brown skin a *lucid* hue,
Like coral reddening through the darkened wave,
Which draws the dæver to the crimson cave. *Byron.*

LUCERA, an inland town of Naples, in the Capitanata. Strabo says, 'It had lost much of its splendor in the time of Augustus.' The only relic of Roman architecture now to be seen is a tower in the middle of the castle; but medals are frequently found. It is the see of a bishop. Population 8400: thirty-two miles north-east of Benevento.

LUCERES, in Roman antiquity, the third in order of the three tribes into which Romulus divided the people, including foreigners; so

called from the lucus or grove where Romulus opened an asylum.

LUCERIA, in ancient geography, a town of Italy, in Apulia; which in Strabo's time still exhibited marks of Diomed's sovereignty in those parts. It is called by Ptolemy Nuceria; now Nocera de Pagani, in Naples.

LUCERNA, a small town and citadel of Piedmont. Population 1200; six miles south of Pinerolo.

LUCERNE, a canton in the heart of Switzerland, adjacent to those of Zurich, Schweiz, and Unterwalden. Its superficial extent is about 740 square miles. It is one of the flattest portions of Switzerland, the north consisting of large plains, while the south, though less level, contains only a part of the mountains that border on the lake of Lucerne. Both the soil and climate are favorable to agriculture, and it is watered by the Reuss, Emme, Entlen, Weger, Wyna, Sur, and Eschenbach. It contains several small lakes, such as Sempach, Mauern, Reichen, and the Red Lake. Cattle, horses, goats, sheep, and hogs are reared, as well as corn, in abundance; as also flax and hemp, vines, &c. Several of the towns drive a good carrying trade. Lucerne is the most powerful of the Catholic cantons, and a papal nuncio has resided at the capital ever since the reformation. The canton is divided into the five districts of Lucerne, Entlibuch, Willisau, Sursee, and Hochdorf; each district is subdivided into four quarters. Population 87,000.

LUCERNE, the capital of the canton of that name, is situated on the Reuss, where it issues from the lake of Lucerne. The town stands on both sides of the river, over which are four bridges. The view from these bridges is very picturesque. The town stands on a gentle eminence, at the foot of Mount Pilate, surrounded by a wall and towers, and contains several handsome edifices, and neat groups of houses on the lake. The chief public buildings are the town-hall, watch-tower, and arsenal, in all of which there are curious antiquities. The churches are of Gothic architecture; and there are in the town several monasteries and convents. Here is also a college or high school, belonging formerly to the Jesuits, who were restored in the year 1819, contrary to the wishes of many of the inhabitants. There are various collections of books, paintings, and curiosities in Lucerne; but the most remarkable is the model or map en relief of Switzerland, by general Pfyster. Its commerce is chiefly in corn, and a transit business. Population nearly 7000: forty-two miles east of Berne, and sixteen west by north of Schweiz.

LUCERNE, called also the lake of Waldstadte, a lake of Switzerland, between the cantons of Unterwalden, Lucerne, Schweiz, and Uri. Its length is about twenty-five English miles, but its breadth is unequal, as it consists of a number of detached parts, some of them of considerable size, and forming in a manner separate lakes. The largest of them take their names from the chief places on their banks; thus the lake of Lucerne Proper, the lake of Alpnach, the lake of Stanz, and the lake of Uri. Its general breadth

is two, three, or four miles; the elevation of its surface above that of the sea 1380 feet; and its depth is in some places 600 feet. It is the largest lake in the interior of Switzerland, and, though its banks are not enlivened by towns or luxuriant vegetation, the scenery is striking. From different spots on the surface of the lake may be counted more than twenty-five mountains, comprising some of the highest of the Alps, such as the Pilatusberg, Mount Righi, and the Furca. While these form promontories and cliffs, which increase the beauties of the scenery, they give rise to blasts, which sometimes render it dangerous to navigate the lake.

LUCIA (St.), or ST. ALOUSIE, one of the Caribbee Islands, is about twenty-two miles long and twelve broad; Carenage, the chief town, being in lat. $13^{\circ} 57' N.$, and long. $61^{\circ} 7' W.$ It was first settled by the French in 1650; but was reduced by the English in 1664, who evacuated it in 1666. The French immediately resettled the island, but were again driven away by the Caribs. As soon as the savages were gone, the former inhabitants returned for a short time; but, being afraid of falling a prey to the first privateer that should visit their coasts, they removed to other French settlements that were stronger, or might be better defended. There was then no regular colony at St. Lucia; it was only frequented by the inhabitants of Martinico, who came thither to cut wood, and to build canoes, and who had considerable docks on the island. In 1718 it was again settled by the French; but four years after it was given by the British court to the duke of Montagu, who was sent to take possession of it. This occasioned some disturbance between the two courts; which was settled, however, by an agreement made in 1731, that, till the respective claims should be finally adjusted, the island should be evacuated by both nations, but that both should have wood and water there. This agreement furnished an opportunity for private interest to exert itself. The English no longer molested the French in their habitations; but employed them as their assistants in carrying on with richer colonies a smuggling trade, which the subjects of both governments thought equally advantageous. This trade continued more or less considerable till the treaty of 1763, when St. Lucia was ceded to the crown of France. After that time the colony flourished. In the beginning of 1772 the number of white people amounted to 2018 souls, men, women, and children; that of the blacks to 663 freemen, and 12,795 slaves. The cattle consisted of 928 horses and mules, 2070 horned cattle, and 3184 sheep and goats. There were thirty-eight sugar plantations, which occupied 978 pieces of land; 5,395,889 coffee-trees; 1,321,600 cocoa plants; and 367 plots of cotton. There were 706 dwelling places. The annual revenue at that time was about £175,000, which, according to the abbé Raynal, must have increased one-eighth yearly for some time. It was taken by the British fleet, under admirals Byron and Harrington, in 1779, but restored to France at the peace of 1783. It was again taken by the British troops, under Sir Charles Grey and Sir John Jervis, in 1794; but in 1795 the French,

negroes, and mulattoes rose, and were so successful, that in April, 1795, they were in possession of the whole island, except Morne Fortune which surrendered in May. But on the 26th of May, 1796, that fort and the whole island were recovered by general Abercrombie, after an obstinate resistance; and 2000 men taken prisoners. It was ceded to the French by the treaty of peace in 1801-2, and retaken in the late war, which began the year after. The soil of St. Lucia is tolerably good, even at the sea side; and is much better further up the country. The whole of it is capable of cultivation, except some high and craggy mountains, which bear evident marks of volcanoes. In one deep valley there are still eight or ten ponds, the water of which boils up, and retains some of its heat at the distance of 6000 toises from its reservoirs. The air in the inland parts is unwholesome; but becomes less noxious as the woods are cleared. On some parts of the coast the air is still more unhealthy, by the waters of the rivers, which spring from the foot of the mountains, not having sufficient slope to wash down the sands with which the ocean stops up their mouths.

Le Carenage, the chief place of the island, is about the middle of the west side. Nature has here formed a spacious and secure harbour, in which thirty sail of the line may lay in perfect safety during the hurricane months, and the largest ships may heave down by the shore. The entrance is so narrow that but one ship can enter at a time, and the wind blowing constantly out, she must be towed or warped in.

LUCIA (St.), one of the Cape de Verd Islands, is three leagues from St. Vincent, the two islands having three or four rocky inlets between them, is twenty-four miles long, mountainous, and uninhabited. On the south-east is a good road within two small islands called Itound and White Islands. On the west side there is no water. It abounds with goats, sea and land fowl, tortoises, &c.

LUCIAN, or LUCIANUS, a celebrated Greek author in the first century, born at Samosata, in the reign of Trajan. He studied law, and practised some time as an advocate; but afterwards commenced rhetorician. He lived to the time of Marcus Aurelius, who made him register of Alexandria in Egypt; and, according to Suidas, he was at last worried by dogs, in his ninetyeth year, A. D. 180. His Dialogues and other works are written in elegant Greek. In these he has joined the useful to the agreeable, instruction to satire, and erudition to elegance. He has been censured as an impious scoffer at religion; but surely religion consists neither in the theology of the Pagan poets, nor in the extravagant opinions of philosophers, which he justly ridicules.

LUCIANISTS, or LUCANISTS, a religious sect so called from Lucianus, or Lucanus, a heretic of the second century, a disciple of Marcion, whose errors he followed. Epiphanius says he, abandoned Marcion, teaching the people ought not to marry, and yet other authors mention that he held this error in common with Marcion and other Gnostics. He denied the immortality of the soul, asserting it to be material.

LUCIFER, in astronomy, is the bright planet

Venus, which either goes before the sun in the morning, and is our morning star, or in the evening follows the sun, and then is called *Hesperus*, or the evening star.

LUCIFER, in ecclesiastical history, a celebrated bishop of Cagliari, in Sardinia, who gave rise to a schism, by not admitting the decree of the council of Alexandria, A. D. 362, for receiving the Arian bishops, who recanted their errors. He was banished by Constantius for defending the Nicene doctrine concerning the Trinity. He died A. D. 370. His works were published at Venice.

LUCIFERA, in mythology, a surname given to Diana, under which title she was invoked by the Greeks in childbed. She was represented as covered with a large veil, interspersed with stars, bearing a crescent on her head, and holding in her hand a lighted flambeau.

LUCIFERIANS, a religious sect, who adhered to the schism of Lucifer. See **LUCIFER**. St. Augustine intimates that they believed the soul, which they considered as of a material nature, to be transmitted to the children from their fathers. They increased greatly in Gaul, Spain, Egypt, &c. There were but two Luciferian bishops, but a great number of priests and deacons. They bore a great aversion to the Arians.

LUCILIUS (Caius), a Roman knight and Latin poet, was born at Suessa in Italy, about 140 B. C. He served under Scipio Africanus, in the war with the Numantines, and was in great favor with that celebrated general, and with Lælius. He wrote thirty books of satires, and some learned men ascribe the invention of satire to him; but M. Dacier insists, that Lucilius only gave a more elegant turn to that kind of poetry, than his predecessors Ennius and Pacuvius had done. From Horace, who refers to them several times in his own satires, it appears that he imitated the old Greek comedians in marking out by his censure individuals notorious for their vices, even those of the very highest rank. Though superior to his poetical predecessors at Rome, and though he wrote with great roughness and inelegance, he gained many admirers. By Horace he is compared to a river which rolls upon its waters precious sand, accompanied with mire and dirt. Of his thirty books of verses only a few scattered fragments are come down to modern times. His fragments have been carefully collected by Francis Douza at Leyden, in 1599, with notes.

LUCINA, a goddess among the Romans, who presided over women in labor. Some take her to be Diana, others Juno, others make her a distinct goddess, daughter of Jupiter and Juno. She is called Lucino, because she brought children to light; from the Latin *lux*, light. The Greeks called her *Ilithyia*.

LUCK, *n. s.* } Sax. *luc*; Goth. *lucka*;
LUCKILY, *adv.* } Belg. *luk*; Teut. *gluck*,
LUCKINESS, *n. s.* } *glucke*; à Gr. γλῆκη, dulce,
LUCKLESS, *adj.* } Minshew. Fortune, particularly good fortune;
Lucky, }
 chance; accident: luckily is happily; by good hap or fortune: luckiness, happiness; happy hit: luckless, unhappy, unfortunate: lucky, fortunate, 'happy by chance,' if such luck there be.

Glad of such *luck*, the *luckless lucky* maid
 A long time with that savage people staid,
 To gather breath in many miseries. *Spensor.*

But I more fearful, or more *lucky* wight,
 Dismayed with that deformed, dismal sight,
 Flest fast away. *Færie Queene.*

Farewel, good *luck* go with thee.

Shakspeare:

I did demand what news from Shrewsbury,
 He told me that rebellion had ill *luck*,
 And that young Harry Percy's spur was cold.

Id.

Never shall my thoughts be base,
 Though *luckless*, yet without disgrace.

Suckling.

He forced his neck into a noose,
 To shew his play at fast and loose;
 And, when he chanced to escape, mistook,
 For art and subtlety, his *luck*. *Hudibras.*

Some such method may be found by human industry or *luck*, by which compound bodies may be resolved into other substances than they are divided into by the fire. *Boyle.*

That part of mankind who have had the justice, or the *luck*, to pass, in common opinion, for the wisest have followed a very different scent.

Temple.

It is the pencil thrown *luckily* full upon the horse's mouth, to express the foam, which the painter with all his skill could not form. *Dryden's Dufresnoy.*

What else but his immoderate lust of power,
 Prayers made and granted in a *luckless* hour.

Dryden.

He who sometimes lights on truth, is in the right but by chance; and I know not whether the *luckiness* of the accident will excuse the irregularity of his proceeding. *Locke.*

The guests are found too numerous for the treat,
 But all, it seems, who had the *luck* to eat,
 Swear they ne'er tasted more delicious meat. *Tate.*

Such, how highly soever they may have the *luck* to be thought of, are far from being Israelites indeed. *South.*

Perhaps some arm more *lucky* than the rest,
 May reach his heart, and free the world from bondage. *Addison's Cato.*

It happens *luckily* for the establishment of a new race of kings upon the British throne, that the first of this royal line has all high qualifications. *Addison.*

As little reckt I sorrow's power,

Until the flowery snare

O' witching love, in *luckless* hour,

Made me the thrall o' care. *Burns.*

Patron of all those *luckless* brains,

That to the wrong side leaning,

Indite much metre with much pains,

And little or no meaning. *Cowper.*

LUCKNOW, a district of the province of Oude, Hindostan, situated between the twenty-sixth and twenty-seventh degrees of north latitude. The soil, though in general sandy, when well watered, is very productive, and yields cotton, and all the grains of India except rice. Here also abound excellent vines, mulberries, and oranges. The inhabitants are intelligent, and considerably cultivated.

LUCKNOW, a city of Hindostan, capital of the province of Oude, is situated on the south bank of the Goomty, which falls into the Ganges between Binaras and Ghazypore, and is navigable for middling-sized boats at all seasons of the year. It is an ancient city, but, after being for a

long time the residence of the nabobs of Oude, was abandoned by Shujau ad Dowleh, after the battle of Baxar, for Fyzabad, which he made his capital. On his death, however, in 1774, his successor returned to Lucknow, and expended large sums on his palace and the other public buildings. He also added an iron bridge across the river. The streets are still narrow and very irregular. In the vicinity, however, is the dwelling of the British resident, and other European inhabitants; and adjoining to the palace is the cantonment of one of the East India Company's regiments. The gilt domes of the mosques, and the mausoleum of Asoph ad Dowleh, give it a showy appearance; but the situation of the place is bad, and the soil is a white sand, which, in the hot weather, is driven about by the wind, and penetrates every thing. The nabob's gardens are handsome. His army has been much reduced; but few princes can make a greater display of pomp on state occasions; and his repositories and library contain a number of curiosities. In the vicinity are numerous Hindoo and Mahomedan sacred tombs. Population about 300,000. Long. 80° 55' E., lat. 26° 24' N.

LUCKNOWTY. See **GOUR.**

LUCKPUT BUNDER, a town of Hindostan, province of Cutch. It is situated about thirty miles up the Lory River, which is only navigable by small vessels. It is defended by a good fort, and belongs to the Ameers of Sind. Long. 68° 58' E., lat. 23° 47' N.

LUCKY BAY, a bay on the south coast of New Holland, in the Archipelago de Recherche.

LUCKYPORE, a town of Bengal, in the district of Tipperah, is situated inland from the east bank of the Megna, with which it communicates by a small river. The East India Company have an extensive factory here, for the manufacture or purchase of baftahs and other coarse cotton cloths.

LUCON, or **LUCONIA,** the most considerable of the Philippine Islands, in the Indian Seas, is so called from a native word *luson*, written *luçon* by the Spaniards, the name of a kind of pestle used by the natives to free their rice from the husk, and which the first discoverers took for a war club. The Indians, or Malays, of the Philippines are divided into many nations, the two principal of which are the Tagalls, in Luconia, and the Bissayas, in the central islands. The Tagalls believe themselves to be descended from a colony of Bornean Malays: one writer makes the Malay population of Luconia, subject to the Spaniards, 1,500,000.

The island is of very irregular shape, the southern extremity being formed of a number of peninsulas, making two great bays, that of Manilla on the west, and of Lampoon on the east. A great portion of the tract between these bays is occupied by the lake of the bay, forty-five leagues in circuit, and which is formed by the waters of fifty to sixty rivers and rivulets, and empties itself into Manilla Bay, by the river Passig. The lake is navigable by large boats, and in it is an island nine leagues in circuit, which, though very fertile, is uninhabited. It would appear that the lake has a communication with some of the volcanoes that surround it, its

waters being at times strongly impregnated with sulphur, which destroys the fish. There are also many hot springs in its vicinity. The shores of the lake to the feet of the mountains are well cultivated, producing abundance of rice, indigo of a superior quality, pepper, cocoa, and areca nuts, and logwood. The uncultivated plains abound in wild buffaloes, deer, and hogs.

Luconia produces iron, copper, and gold, of which the latter only is collected in small morsels. The east coast is very mountainous and little productive, the strong easterly winds and atmosphere of the sea destroying vegetation. The mountains on this side are chiefly occupied by the natives, who have fled from the Spanish dominion. The north-east point of the island is Cape Engano, and the north-west Cape Bojador. Manilla, the chief city of the island, and of the Spanish possessions, is situated near the mouth of the Passig, which issues from the lake of the bay. See **MANILLA** and **PHILIPPINES**.

LUCRE, *n. s.*

LUCRATIVE, *adj.* } Latin *lucrum*. Gain; profit; pecuniary emolument: generally used in a bad sense: yet lucrative (of which lucriferosus is an obsolete synonyme) does not partake this character; as it is quite clear that being lucrative is not the least recommendation of numerous pursuits.

LUCRIFEROUS. } Taking the oversight thereof, not by constraint, but willingly; not for filthy lucre, but of a ready mind. *1st Pet. v. 2.*

Malice and lucre in them

Have laid this woe here.

Shakspeare. Cymbeline.

The trade of merchandize, being the most lucrative, may bear usury at a good rate: other contracts not so. *Bacon.*

Should we not farther, honestly comparing things, easily discern, that it is no such indispensable business, but rather indeed some base dotage in lucre, some inveigling bait of pleasure, some bewitching transport of fancy, that crosseth our devotion. *Barrow.*

They all the sacred mysteries of Heaven,

To their own vile advantages shall turn

Of lucre and ambition. *Milton's Paradise Lost.*

Silver was afterwards separated from the gold, but so small a quantity, that the experiment, the costs and pains considered, was not *lucriferous*. *Boyle.*

A soul supreme in each hard instance tried,
Above all pain, all anger, and all pride,
The rage of power, the blast of publick breath,
The lust of lucre, and the dread of death. *Pope.*

The disposition of Ulysses inclined him to pursue the more dangerous way of living by war, than the more lucrative method of life by agriculture. *Broome.*

Her lucrative task she pursues,

And pilfers with so much address,

That none of their odour they lose,

Nor charm by their beauty the less. *Conper.*

LUCRETIA, a celebrated Roman lady, the wife of Tarquinius Collatinus. Being ravished by Sextus, the eldest son of Tarquin II., she stabbed herself, A. A. C. 509. Her dead body, with the bloody poniard, exposed to the senate, was the signal of Roman liberty; the expulsion of the Tarquins, and abolition of the regal dignity, was instantly resolved on, and carried into execution. See **ROME**.

LUCRETIVS CARUS (Titus), a celebrated Latin poet, descended of an ancient and noble Roman family. He studied at Athens, where he became an Epicurean, and acquired great reputation by his learning and eloquence; but in the flower of his age fell into a frenzy, occasioned by a philtre given him by his wife, who was distractedly fond of him. Lucretius, during the intervals of his madness, versified the doctrines of Epicurus, and composed his six books *De Rerum Naturâ*, which are still extant. It is said that he killed himself in a fit of madness, A. A. C. 54, when fifty-one years old. The most correct edition of Lucretius is that of Simon de Coline. His celebrated poem *De Naturâ Rerum*, though among the earliest classics given to the world by the invention of printing, though published by many successive editors, and though translated into all the modern languages of Europe, has not, till very recently, been purified with much success from innumerable corrupt readings which had accumulated through time and ignorance, to the obscurity and essential injury of the text. This was the more to be lamented, since the originality and superlative beauty of this poet are not the only attractions he possesses. It is a fact, says the late Dr. Mason Good, no less remarkable than true, that the inductive method of Bacon, part of the sublime physics of Newton, and various of the chemical discoveries of our own days, were to a surprising degree anticipated, as to their principles and many important results, by the philosophical poet of Rome. The principal editions of Lucretius are,
